Responses to the reviewer comments of our revised manuscript (acp – 2018-201) titled "***Climate and the September 2014 flood event over Mountainous Jammu and Kashmir, India: Physical explanations based on observations and modelling***" By Sumira et al. submitted for possible publication in the journal *Atmospheric Chemistry and Physics*, Copernicus publications.

Formatted: Font color: Blue

General response:

We express our sincere thanks to the reviewer for his invaluable constructive comments of our manuscript. His encouraging comments helps us a lot to improve the presentation quality of the manuscript. Below, we have provided our one to one responses to the reviewing comments. We hope that the present revised manuscript, written taking into account of all the reviewer comments, will convince the reviewer to make positive recommendations of our manuscript for publication in ACP. Manuscript with changes tracked also enclosed in the end for quick reference.

One to one responses:

The responses are in bold faceted.

MAJOR

1. The presentation quality has to be improved, as I (and both referees) mentioned previously.

The quality of the manuscript is now significantly improved.

2. The title is still not suitable for the content of the article. I would suggest something like: "Analyses of temperature and precipitation in the Indian Jammu-Kashmir for the 1980—2016 period: Implications for remote influence and extreme events"

The title of the manuscript is now changed as suggested by the reviewer.

3. "respectively" is used at many places without "respective" cases.

Carefully avoided now all through the manuscript.

4. Fix the confidence interval you wanted to discuss and then just say "significant" or "insignificant". Otherwise, it would be confusing if you use S=0.01 and S=0.05 (line 30, 31-33, and throughout the article)

The present revised manuscript has taken well this into account.

5. Line 184 and many other places you have used "climatic variations". What are these climatic variations? How do you find the changes or variability in climate without analyzing the temperature, precipitation or related parameters?

Unnecessary usage of "climatic" is now removed

6. Section 4.3: In this section you have only used NAO. So how would you know that this is the main reason for the variability in temperature or precipitation?

Enough care has been taken now to rephrase some sentences so that ambiguous statements are removed.

7. You have also used “climatic” at many places for “climate”

Unnecessary usage of “climatic” is now removed

8. You have used three pages to describe the PV and temperature/rainfall correlation analyses. The sections need to be shortened, as there are no new results. Perhaps, you could describe the connection for a station in detail and then discuss how other station measurements differ from the former

Efforts are applied to shorten this section in the revised manuscript.

MINOR

Line 19: what are these climate settings? Be specific. **Modified**
Line 21: short-tern (similarly long-term) **Corrected**
Line 36: “show” **corrected**
Line 38-39: What are the reasons for the difference? **Explained**
Line 22-24: Just write that you have used measurements from six stations in the valley and long-term simulations from the WRF model. That complex sentence is very hard to comprehend. **Modified accordingly**
Line 51: climate change **Corrected**
Line 52: in the coastal **Corrected**
Line 55: “and (4)” **Corrected**
Line 54: “significant” delete “the” **Corrected**
Line 56, 59: remove etc. **Corrected**
Line 67, 68: remove PT when you mention potential temperature surfaces, as you have already mentioned “K” there. Use “e.g. 350 K” **Corrected**
Line 69: PV is conserved everywhere at all times? **Modified with additional phrases**
Line 77—78: western disturbances and monsoon. Else, write all those “etc” things there. There are several “etc” in this manuscript, which is not a good “word” choice. If you know the related processes write those or give some examples. **Corrected**
Line 78: the vertical distribution **Corrected**
Line 79-80: please rephrase the sentence, very difficult to understand this now **Modified**
Line 84: write like, “Kashmir floods in 2014, Leh floods in 2010” **Corrected accordingly**
Line 87: and distinguish **Corrected**
Line 94: PV is considered as Rossby wave activity? **It is a measure of Rossby wave activity, which is already mentioned in the text.**

Line 100: “Jain (2009)” **Corrected**
Line 106: that minimum **Corrected**
Line 112: what are these hydrometeorological parameters? Be specific. **Corrected**
Line 114: data pose **Corrected**
Line 115—116: climatic variations in weather parameters? Please write the change in that particular parameter, instead of that phrase. **Corrected**
Line 117: are necessary for understanding **Modified**
Line 119: climate of the Himalaya **Corrected**
Line 127: “, respectively” and similarly at other places **Corrected**
Line 141: hard to comprehend this sentence “to be clarified with NAO only”
The sentences here are modified so that it can be now comprehended easily.

Line 144: not the connection between NAO INDEX and precipitation, but NAO and precipitation. Index is just a number or set of numbers. Rewrite similar statements elsewhere in the article. **Rewrited as suggested**

Line 161: write “3.1 Measurements and Model simulations”
It is now written as per the reviewer suggestion
Line 163: Please write “The data are analysed carefully….” **Corrected**
Line 170: Space before “. Trends…” **Corrected**
Line 184: This is not correct. You are just correlating the NAO Index with temperature and precipitation. There is no “climatic variations of mean temperature” unless you define it. **Modified accordingly**
Line 221-222: Is this the best parameterization scheme for the Indian region?

We don’t claim here that this is the best parameterization and already cited earlier reference which adopted similar schemes as in the present manuscript.

Line 225: Delete “Priyanka”, Just Ghosh et al. **Corrected**
Line 231: What are “climate data”? Specify the data here. **Corrected**
Line 287, 290: “insignificant level” for confidence intervals. You need to define that with respect to your estimates (e.g. 95% CI). Just write that they are “statistically insignificant”. **Corrected**
Line 296: Influence of North Atlantic Oscillation **Corrected**
Line 306-307: This is not a result, but a guess. If you find something significant from your study, please indicate that clearly. “The analyses show significant correlation between NAO Index and precipitation; indicating a possible connection between NAO and rainfall in the Kashmir, where the positive correlation suggests …..” something like this. **Rewritten accordingly**
Line 309: “at all stations...” **Corrected**
Line 310: downscaled **Corrected**
Line 311: “0.47” is good correlation? **Modified this sentence**
Line 317-318: “A detailed study on this topic will be presented in a separate paper.” Write something similar. **The sentence is rewritten as per the advice of the reviewer**
Line 334—335: write something this sort: ”This is consistent with the model results of

Wiltshore (2013) ……" **The sentence is rewritten accordingly as suggested by the reviewer**

Line 340-341: give a reference for this statement

Now Reference Barnes et al., 2016 is added

Line 357: Please note the study period also, as the trends depend on the length (period of analyses) of the data sets, and then compare trend during similar periods.

Now comparision has been done with information of study period.

Line 362: Give reference for this statement. **It is now provided**

Line 396: "Furthermore" **Corrected**

Line 407: "propagate" **Corrected**

Line 408: delete "clear from studies". This may not be very clear for everyone. Write "This study shows that" or "suggested" or use similar wordings **Corrected**

Line 412: (e.g. Screen and Simmonds, 2014) **e.g. is now added**

Line 412: In northern India **Corrected**

Line 424: They also note that **Corrected**

Line 450: delete "PT" and at other places too **Corrected at all places**

Line 453: "Therefore, PV in the upper troposphere varies" **Corrected accordingly**

Line 455-456: What are these sometimes and other times? years? Be specific here. Rephrase the sentence without "One can" **It is now modified**

Line 465—4666: I am bit confused about the statement. How can you state that the particular correlation between PV and rainfall in 1999—2000 is just due to climate change? There was no effect of this climate change in other years? What do you mean by climate change here? I thought you are analyzing the changes in climate of the region in this study. **Rephrased this sentence**

Line 477-478: The measurements show that the stations located near the Greater Himalaya… **Corrected**

Line 485: Equatorward **Corrected**

Line 486: "at both" and "except for January—March "**Corrected**

Line 502-503: The observations show that the high altitude mountains … **Corrected**

Line 510: the connection between PV and precipitation … **Corrected**

Line 512: PV and precipitation **Corrected**

Line 518: conditions such as local convection. **Corrected**

Line 530: subtropical **Corrected**

Line 532/535: there is no mechanism to "attract" the moisture there. Use "transport" Instead **Transported replaced attracted**

Line 539: what is "drifting climatically"? **The centere of the Subtropical jet which is now mentioned**

Line 547: What is "climatic increase in tropospheric warming"? **It is long-term variation**

Line 548: space before the bracket **Corrected**

Line 549: Space after the full-stop **Corrected**

Line 550: combined effect of **Corrected**

Line 554: again "climatically shifted"? **Corrected**

Look for corrections at other places …. **Corrections are done all through the manuscript**.

Abstract

~~The~~ Local weather and climate of the Himalayas are ~~is very~~ sensitive and interlinked with ~~to~~ global scale changes in climat~~eic variations because of its fragile environmental and climatic settings~~as the hydrology of this region is mainly governed by snow and glaciers. There are clear and strong indicators of climate change reported for the Himalayas, particularly the Jammu and Kashmir region situated in the western Himalayas. In this study, using observational data, ~~the~~ detailed characteristics of long- and short~~-~~-term as well as localized variations of temperature and precipitation are analysed for these six meteorological stations, namely, ~~(~~Gulmarg, Pahalgam, Kokarnag, Qazigund, Kupwara and Srinagar~~)~~ of~~over~~ Jammu and Kashmir, India during 1980-2016. In addition to analysis of stations observations, we also utilized the dynamical downscaled simulations ~~for a period of 37 years~~ of WRF model and ERA-Interim (ERA-I) data for the study period.~~during 1980-2016 by making use of observed stations data, WRF model downscaled monthly-averaged surface temperature and precipitation and ERA-interim (ERA-I) reanalysis data.~~ The annual and seasonal temperature and precipitation changes were analysed by carrying out Student's t-test, Mann-Kendall, Linear regression and Cumulative deviation statistical tests. The results show an increase of 0.8°C in average annual temperature over thirty seven years (from ~~during~~ 1980 to ~~-~~2016) with higher increase in maximum temperature (0.97°C) compared to minimum temperature (0.76°C). Analyses of ~~-~~annual mean temperature at all the stations reveal that the ~~higher rise at~~ high-altitude stations of Pahalgam (1.13°C) and Gulmarg (1.04°C) ~~at the confidence level of S=(0.01)~~ exhibit a steep increase and statistical significant trends. Precipitation patterns in the valley such as at Gulmarg and Pahalgam show a slight and definite decrease in the annual rainfall~~precipitation~~ at Gulmarg and Pahalgam stations ~~at the confidence level of S = 0.1 to 0.05~~. Seasonal

Formatted: Font: (Default) Times New Roman, 14 pt, Bold, Complex Script Font: Times New Roman, 14 pt, Bold analyses show significant increasing trends increase in the winter and spring temperatures at all stations at the confidence level of S = 0.01 to 0.05 with prominent decrease in spring precipitation. at S = 0.01 to 0.05. The present study also reveals that variation in temperature and precipitation during winter (December - March) has a close association with the North Atlantic Oscillation (NAO). Further, the observed temperature data (monthly averaged data for 1980-2016) at all the stations shows good correlation of 0.86 with the results of WRF and therefore the model downscaled simulations arecan be considered as a valid scientific tool for the studies of climateic change studies in this region. Though the correlation between WRF model and observed precipitation is significantly strong, the WRF model underestimates significantly the rainfall amount, which necessitates the need for the sensitivity study of the model using the various microphysical parameterization schemes. Using ERA-IThe potential vorticities in the upper troposphere troposphere are obtained from ERA-I over the Jammu and Kashmir region indicate , it is found that the extreme weather event of September 2014 occurred due to the breaking of intense atmospheric Rossby wave activity over Kashmir. As the wave could transportdrag a large amountlots of water vapour from both the Bay of Bengal and Arabian Sea and dump them over the Kashmir region through wave breaking, it is probably speculated to be resulted in the historical devastating flooding of the whole Kashmir valley in the first week of September 2014. This, which was accompanied by extreme rainfall events measuring more than 620 mm in some parts of the Pir Panjal range in the South Kashmir.

1. Introduction

Climate change is a real Earth's atmospheric and surface phenomenon and the influences of which on all the spheres of life are considered significant almost everywhere in the world at least in the past few decades. Extreme weather events like anomalously large floods and unusual drought conditions associated with changes in climate change play havoc with livelihoods of even established civilizations particularly in the coastal and high-mountainous areas. Jammu and Kashmir, India, located in the Western Himalayan region, is one such cataclysmic mountainous region where the significant influence of climate change on local weather has been observed for the last few decades; (1) shrinking and reducing glaciers, (2) devastating floods, (3) decreasing winter duration and rainfall, and (4) increasing summer duration and temperature etc. (Solomon et al., 2007; Kohler and Maselli, 2009; Immerzeel et al., 2010; Romshoo et al., 2015; Romshoo et al., 2017). Western disturbances (WD) is considered as one of the main sources of winter precipitation for the Jammu and Kashmir region, which brings water vapour mainly from the tropical Atlantic Ocean, Mediterranean Sea, Caspian Sea and Black sea etc. Though WD is perennial, but it is most intense during northern winter (December-February; Demri et al., 2015). Planetary-scale atmospheric Rossby-waves have potential to significantly alter the distribution and movement of WD according to their intensity and duration (few to tens of days). Since WD is controlled by planetary-scale Rossby waves in the whole troposphere of the subtropical latitude region, diagnosing different kinds of precipitation characteristics is easier with the help of potential vorticity (PV) at 350K potential temperature (PT) and 200 hPa level pressure surface (PS) as they are considered as proxies for Rossby wave activities (Ertel, 1942; Bartels et al., 1998; Demri et al., 2015 and Hunt et al 2018a). Here onwards, it will be simply called PV at 350 K and 200 hPa surfaces. For example, (Postel and Hitchman, 1999; Hunt 2018b) studied the characteristics of Rossby wave breaking (RWB) events occurring at 350K PT surface transecting the subtropical westerly jets. Similarly, Waugh and Polvani (2000) studied RWB characteristics at 350K PT surface in the Pacific region during northern fall–spring with emphasis on their influence on westerly ducts and their intrusion into the tropics. Since PV is a conserved quantity on isentropic and isobaric surfaces (ISOES & ISOBS) when there is no exchange of heat and pressure respectively, it is widely used for investigating large-scale dynamical processes associated with frictionless and adiabatic flows. Moreover, all other dynamical parameters, under a given suitable balanced-atmospheric-background condition, can be derived from PV and boundary conditions (Hoskins et al., 1985).

Divergence of the atmospheric air flows near the upper troposphere is larger during precipitation, leading to increase in the strength of PV. Because of which, generally there will be a good positive correlation between variations in the strength of PV in the upper troposphere and precipitation over the ground provided that the precipitation is mainly due to the passage of large-scale atmospheric weather systems like western disturbances, and monsoons etc. Wind flows over topography can significantly affect the verticalheight distribution of water vapour and precipitation characteristics. Because of this, one can expect that the positive correlation between variations in PV and precipitation can be modified significantly. depending upon both the topography and wind flow strength. These facts need to be taken into account while finding long-term climatic variations of precipitation near mountainous regions like the western Himalaya. The interplay between the flow of western disturbances and topography of the western Himalaya further complicates further the identification of source mechanisms of extreme weather events (Das et al., 2002; Shekhar et al., 2010) like the ones that occurred in the western Himalayan region; 2014 Kashmir floods in 2014 and, 2010 Leh floods in 2010, in the Jammu and Kashmir region and Uttrakhand floods in region in 2013. Kumar et al. (2015) also noted that the major flood events in the Himalayas are related to the changing precipitation intensity in the region. This necessitates making use of the proper surrogate parameters like PV and distinguishing between different source mechanisms of extreme weather events associated with both the long-term climatic impacts of remote origin and short-term localized ones like organized convection (Romatschke and Houze 2011; Rasmussen and Houze 2012; Houze and Rasmussen 2016; Martius et al., 2012).

The main aim of the present study is to investigate long-term (the climateic) variation of surface temperature and precipitation over the Jammu and Kashmir, India region of the western Himalayas in terms of of its connections with NAO and atmospheric Rossby wave activity in the upper troposphere. Since PV is considered as a measure of Rossby wave activity, the present work analyses in detail, for a period of 37 years during 1980-2016, monthly variation of PV (ERA-interim reanalysis data, Dee et al., 2001) in the upper troposphere (at 350 K potential temperature and 200 hPa surfaces pressure surfaces) and compares it with observed surface temperature and rainfall (India Meteorological Department, IMD) at six widely separated mountainous locations with variable orographic features (Srinagar, Gulmarg, Pahalgam, Qazigund, Kokarnag and Kupwara). There exist several reports on climatological variation of hydro-meteorological parameters in various parts of the Himalayas. For example, Kumar and Jain (2009) and Bhutiyani et al. (2010) found an increase in the temperature in the north-western Himalayas with significant variations in precipitation patterns. Archer and Fowler (2004) examined temperature data of seven stations in the Karakoram and Hindu Kush Mountains of the Upper Indus River Basin (UIRB) in search of seasonal and annual trends using statistical test like regression analysis. Their results revealed that mean winter maximum-temperature has increased significantly while mean summer minimum-temperature declined consistently. On the contrary, Lui et al. (2009) examined long-term trends in minimum and maximum temperatures over the Tibetan mountain range during1961-2003 and found that minimum temperature increases faster than maximum temperature in all the months. Romshoo et al. (2015) observed changes in snow precipitation and snow-melt-runoff in the Kashmir valley and attributed the observed depletion of stream flow to the changing climate in the region. Bolch et al. (2012) reported that the glacier extent in the Kaorakoaram range is increasing.

These contrasting findings of long- -term variations in temperature and precipitationhydro-meteorological parameters in the Himalayas need to be verified by analyzing long-termmore historic climatologicalic data available in the region. However, the sparse and scanty availability of regional climate data poses challenges in understanding the complex microclimate in this region. Therefore, studying the relationship of recorded regional (Jammu and Kashmir) climatic variations in temperature and precipitationweather parameters with remote and large-scale weather phenomena such as the North Atlantic Oscillation (NAO), and El Niño Southern Oscillation (ENSO) isbecome necessarity for understanding the physical processes that control the locally observed variations (Ghashmi, 2015). Archer and Fowler (2004) and Iqbal and Kashif (2013) found that large-scale atmospheric circulation like NAO influences significantly the climateic condition of the Himalayas. However, detailed information about variation in temperature and precipitation and its teleconnection with observed variations of NAO is inadequately available for this part of the Himalayan region (Kashmir Valley).

2. Geographical setting of Kashmir

The inter mountainous valley of Kashmir has a unique geographical setting and it is located between the Greater Himalayas in the north and Pir Panjal ranges in the south, roughly within the latitude and longitude ranges of 33^0 55´ to 34^o 50´ and 74^o30´ to 75^o 35´- respectively (Fig.1). The heights of these mountains range from about 3,000 to 5,000 m and the mountains strongly influence the weather and climate of the region. Generally the topographic setting of the six stations, though variable, could be broadly categorized into two; (1) stations located on plains (Srinagar, Kokarnag, Qazigund and even Kupwara) and (2) those located in the mountain setting (Gulmarg, Pahalgam). Physiographically, the valley of Kashmir is divided into three regions; Jhelum valley floor, Greater Himalayas and Pir Panjal. In order to represent all the regions of the valley, six meteorological stations located widely with different mean sea levels (msl), namely, Gulmarg (2740m), Pahalgam (2600m), Kokarnag (2000m), Srinagar (1600m), Kupwara (1670m) and Qazigund (1650m) were selected for analyses of observed weather parameters.

The Kashmir valley is one of the important watersheds of the upper Indus basin harbouring more than 105 glaciers and it experiences the Mediterranean type of climate with marked seasonality (Romshoo and Rashid, 2014). Broadly, four seasons (Khattak et al 2011; Rashid et al., 2015) are defined for the Kashmir valley; winter (December to February), spring (March to May), summer (June to August), and autumn (September to November). It is to be clarified here that while defining the period of ~~with respect to~~ NAO (Fig. 4) ~~only,~~ it is considered December-March as winter months as defined by Archer and Fowler (2004) and Iqbal and Kashif (2013) and in all other parts of the manuscript it is~~,~~ December-February ~~is considered as winter season~~ as per the IMD definition. ~~This is because, for the NAO index, normally December-March is considered as northern winter and we adopted the same definition here (Archer and Fowler, 2004; Iqbal and Kashif, 2013). The result of linkage between winter NAO index and Kashmir precipitation does not affect other results of the present work.~~ The annual temperature in the valley varies from about -10℃ to 35℃. The rainfall pattern in the valley is dominated by winter time precipitation associated with western disturbances (Dar et al., 2014) while the snow precipitation is received mainly in winter and early spring season (Kaul and Qadri, 1979).

2. Data and Methodology

India Meteorological Department (IMD) provided 37 years (1980-2016) of data of daily precipitation, maximum ~~temperature~~ and minimum temperatures for all the~~se~~ six stations. Monthly averaged data were further analysed to find long-~~-~~term variations of ~~the~~ weather parameters. Statistical tests including Mann-Kendall, Spearman Rho, Cumulative deviation, Student's t-test were performed to determine long term-~~-~~trends and turning point of weather parameters with statistical significances. Similar analyses and tests were performed also for the Weather and Research Forecasting (WRF) model simulated and ERA-Interim reanalyses data (0.75° by 0.75° spatial resolution in the horizontal plane, monthly averaged time resolution) of same weather parameters and for the NAO index. Brief information about these data sets is provided below.

3.1 Measurements and model simulations~~Observational and model datasets used in this study~~

The obtained observational data are~~were~~ analysed -carefully ~~analysed~~ for homogeneity and missing values. Analyses of ratios of temperature from the neighbouring stations with the Srinagar station were conducted using relative homogeneity test (WMO, 1970). It is found that there is no significant inhomogeneity and data gap for any station. Few missing data points were linearly interpolated and enough care was taken not to make any meaningful interpretation during such short periods of data gaps in the observations. Annual and seasonal means of temperature and precipitation were calculated for all the stations and years. To compute seasonal means, the data were divided

Formatted: Font: (Default) Times New Roman, Bold, Complex Script Font: Times New Roman, Bold

Formatted: Font: Bold, Complex Script Font: Bold

Formatted: Font: (Default) Times New Roman, Bold, Complex Script Font: Times New Roman, Bold into the following seasons: winter (December to February), spring (March to May), summer (June to August) and autumn (September to November). Trends in the annual and seasonal means of temperature and precipitation were determined using Mann–Kendall (non-parametric test) and linear regression tests (parametric test) at the confidence levels of S = 99% or (0.01), S = 95% or 0.05 and S = 90% or 0.1. ~~-~~These tests have been extensively used in hydro meteorological data analyses as they are less sensitive to heterogeneity of data distribution and least affected by extreme values or outliers in data series. Various methods have been applied to determine change points of a time series (Radziejewski et al., 2000; Chen and Gupta, 2012). In this study, change point in time series of temperature and precipitation was identified using cumulative deviation test and Student's t test (Pettitt, 1979). This method detects the time of significant change in the mean of a time series when the exact time of the change is unknown (Gao et al., 2011).

~~The data of~~ W~~w~~inter NAO index during 1980–2010 were obtained for further analyses from Climatic Research Unit ~~were obtained for analyses from~~ through the web link https//www.cru.uea.ac.uk/data. The winter (December - March) NAO index is based on ~~the~~ difference of normalized sea level pressure (SLP) between Lisbon, Portugal and Iceland, which is available from 1964 onwards. Positive NAO index is associated with stronger-than-average westerlies over the middle latitudes (Hurrell, 1997). Correlation between ~~climatic variations of~~ mean (December-March) temperature, precipitation and NAO index was determined using Pearson correlation coefficient method. To test whether the observed trends in winter temperature and precipitation are enforced by NAO, linear regression analysis (forecast) was performed (Fig. 4e and f). The following algorithm ~~from Microsoft Excel defines the forecast method applied here. The forecast algorithm~~ calculates or predicts a future value by using existing values. The predicted value is a y-value for a given w~~x~~-value. The known values are existing w~~x~~-values and y-values, and the new value is predicted by using linear regression.

The syntax is as follows

FORECAST(x, known_y's, known_w~~x~~'s)

W~~X~~ is the data point for which we want to predict a value.
Known_y's is the dependent array or range of data (rainfall or temperature).
Known_w~~x~~'s is the independent array or range of data (time).

The equation for FORECAST is a + bw~~x~~, where:

$$a = \hat{y} - b\hat{w} \quad \text{and } b = \sum(w-\hat{w})(y-\hat{y})/\sum(w-\hat{w})^2$$

$$a = \bar{y} - b\bar{x}$$ ~~and~~

and where Ŵ~~x~~ and ŷ~~y~~ are the sample means AVERAGE (known_w~~x~~'s) and AVERAGE (known y's).

3.2. WRF Model configuration

The Advanced Research WRF version 3.9.1 model simulation was used in this study to downscale the ERA-Interim (European Centre for Medium Range Weather Forecasting Re Analysis) data over the Indian Monsoon region. The model is configured with 2 two-way nested domains (18 km and 9-km horizontal resolutions), 51 vertical levels and model top at 10 hPa level. The model first domain extends from longitude from 24.8516 E to 115.148E and latitude from 22.1127S to 46.7629 N while the second domain covers the longitudes from 56.3838E to 98.5722E and latitudes from 3.86047 S to 38.2874 N.

Domain -1 (18 km resolution) extends from longitude from 24.8516 E to 115.148E and latitude from 22.1127S to 46.7629 N

and

Domain -2 (6 km resolution) extends from longitude from 56.3838E to 98.5722E and latitude from 3.86047 S to 38.2874 N

The initial and boundary conditions supplied to WRF model are obtained from ERA-Interim 6-hourly data. Model physics used in the study for boundary layer processes is Yonsei University's non-local diffusion scheme (Hong et al., 2006), the Kain-Fritsch scheme for cumulus convection (Kain and Fritsch, 1993), Thomson scheme for microphysical processes, the Noah land surface scheme (Chen and Dudhia, 2001) for surface processes, Rapid Radiation Transfer Model (RRTM) for long-wave radiation (Mlawer et al., 1997), and the Dudhia (1989) scheme for short-wave radiation. The physics options configured in this study are adopted based on the previous studies of heavy rainfall and Monsoon studies over the Indian region (Srinivas et al., 2013, Madala et al., 2016, Priyanka Ghosh et al., 2016; Srinivas et al., 2018).

For the present study, the WRF model is initialized on daily basis at 12 UTC using ECMWF ERA-I innterim data and integrated for a 36-hour period using the continuous re-initialization method (Lo et al., 2008; Langodan, et al., 2016; and Viswanadhapalli et al., 2017). Keeping the first 12-hours as model spin-up time, the remaining 24-hour daily simulations of the model are merged to get the climate data during 1980-2016. To find out the skill of the model, the downscaled simulations of WRF model are validated forat six IMD surface meteorological stations. The statistical skill scores such as bias, mean error (ME) and root mean square error (RMS) were computed for the simulated temperature against the observed temperature data of IMD.

4. Results and Discussion:

4.1. Trend in annual and seasonal temperature

Tables 1& 2 show the results of statistical tests (Mann-Kendall and linear regression, cumulative deviation and Student's t) carried out on the temperature and precipitation data respectively. All the parametric and nonparametric tests carried out for the trend analysis and abrupt changes in the trend showed almost similar results. Table 1, therefore shows ~~the ~~results of ~~the ~~representative tests where higher values of statistical significance between Mann-Kendall/linear regression test and Cumulative deviation/student's t test are considered. It is evident that there is an increasing trend at different confidence levels in annual and seasonal temperatures of all the six stations (Pahalgam, Gulmarg, Kokarnag, Srinagar, Kupwara and Qazigund), located in different topographical settings (Table 3). During 1980-2016, Pahalgam and Gulmarg, located at higher elevations of about 2500m amsl (above mean sea level), registered ~~an ~~statistically significant increase in average annual temperature by 1.13°C and 1.04°C~~ respectively at the confidence level of S = (0.01)~~ (Fig. 2a).~~ "S in S = 99% or 0.01" indicates statistically significant.~~ It is to be noted that hereafter it will not be mentioned explicitly about the period 1980-2016 and ~~the ~~statistically significant means the confidence level is about 90%~~ce of derived values~~. Kokarnag and Kupwara, located at the heights of about 1800-2000m amsl, showed an increase of 0.9°C and 1°C respectively~~ at S = 99% or 0.01~~ (Fig. 2a). However, Srinagar and Qazigund, located at the heights of about 1700m-1600m amsl, exhibited an increase of 0.65°C and 0.44°C~~ at S=0.05 and 0.1 respectively~~ (Fig. 2a).

~~The ~~A~~a~~nalyse~~i~~s of maximum and minimum temperatures (Table 1 and Fig. 2b) for the~~se~~ six stations reveal~~s~~ higher rate increase in maximum temperature. ~~At S = 0.01, ~~Pahalgam and Kupwara recorded the highest rise of ~1.3°C followed by Kokarnag (1.2°C) and Srinagar (1.1°C). The exception is that Gulmarg and Qazigund (being a hilly station) shows less than 0.6°C in maximum temperature~~ (0.6°C at S = 0.1)~~. The minimum temperature exhibits~~shows~~ a lowest increase of 0.3°Cat Srinagar and highest increase at Gulmarg station of 1.2°C~~ at S = 0.01~~ (Fig. 2c). Analyses of composite seasonal mean of minimum and maximum temperatures in the valley reveal higher increase in maximum temperature in winter and spring seasons. Among four stations (Gulmarg, Pahalgam, Kokarnag and Kupwara), ~~the mean winter temperature of ~~Gulmarg indicates an increase of less than 1°C ~~(1°C at S=0.1)~~ while Pahalgam, Kokarnag and Kupwara shows an increase of 0.9°C, 0.9°C and less than 0.9°C ~~(0.9°C at S = 0.01) ~~respectively (Table 1 and Fig. 2d). On the contrary, Qazigund and Srinagar showed a slight increase of less than 0.4°C and 0.5°C~~ (S=0.05)~~ respectively. Mean spring~~-~~temperature shows higher rise comparing to other seasons temperatures for all the stations. Gulmarg shows an increase of less than 1.4°C~~ (S=0.05)~~. Pahalgam, Kupwara, Kokarnag ~~-~~showed increase of 1.3°C at S = 0.01. Qazigund and Srinagar revealed 0.6°C~~ (S = 0.05)~~ and 1°C increase~~ at S = 0.1~~ respectively as shown in the Table 1 and Fig. 2e. In summer, the temperature rise for Pahalgam is about less than 0.6°C~~ (S = 0.1)~~ and for Gulmarg and Qazigund, it is about 0.4°C and 0.2°C respectively~~at (insignificant level (NS), (~~Table 1). Kupwara, Kokarnag and Srinagar reveal an increase of less than 0.3°C, 0.4°C and 0.1°C ~~-at (S = 0.1)~~ respectively (Fig, 2f). In Autumn, Gulmarg shows an increase of 0.9°C and Pahalgam exhibit~~shows~~ less than 0.6°C~~ (S=0.05)~~. On the contrary Qazigund shows less than 0.4°C at~~ (S=0.1)~~ ~~but~~while Srinagar shows no significant increase in observed temperatures (Fig. 2g and Table 1).

4.2 Trend in annual and seasonal precipitation

The annual precipitation pattern of the valley is comparable to that of temperature with higher decrease observed at the upper elevation stations of Gulmarg and Pahalgam~~. These two stations show average decrease in annual precipitation at S = 0.05 and S = 0.19 respectively~~ (Fig. 3a and Table 2). Similar to temperature, Table 2 provides in detail the test results of Mann-Kendall, linear regression and Student's t. While Kokarnag and Kupwara show significant decrease, ~~at S = 0.1.~~ t~~T~~he lower elevated stations, Qazigund and Srinagar, exhibit insignificant decrease ~~at NS~~ (Fig. 3a). ~~The analysis of~~W ~~w~~inter precipitation ~~reveals maximum~~ decrease is maximum at Gulmarg and Kokarnag followed by Kupwara and Pahalgam ~~at S = 90%~~and it is insignificant decrease for~~. On the other hand,~~ Srinagar and Qazigund ~~display an average insignificant (NS) decrease~~ (Table 2 and Fig. 3b). The ~~while the~~ spring season precipitation exhibits decreasing trend for~~at S = 0.05 at~~ all the six stations with~~Qazigund and Gulmarg and Srinagar (Fig. 3c). Kupwara, Kokarnag and and Kokarnag show decrease at S=0.01 respectively.~~ t~~T~~he lowest decrease of 42mm precipitation ~~during spring season was observed~~ at Kupwara ~~at S=0.01~~ (Table 2).

During ~~the~~ summer months also, precipitation shows~~follows the same~~ decreasing trend for all stations except Qazigund that~~but~~ it is statistically in~~not at~~ significant ~~level (NS) for Gulmarg, Kupwara, Kokarnag, Pahalgam and Srinagar~~ (Fig. 3d, and Table 2). For~~In addition,~~ Qazigund there is ~~shows~~ no apparent trend in summer precipitation. The autumn precipitation also shows insignificant decreasing trend for the stations ~~at Pahalgam, Kupwara, Kokarnag, Srinagar, Gulmarg and Qazigund shows decrease at insignificant level (NS)~~ (Fig. 3e and Table 2). Cumulative test was used to determine the "change point" of trend in the annual and seasonal variations of temperature and precipitation. ~~The~~ R~~r~~esults reveal that the year 1995 is ~~identified as~~ the year of abrupt increase (change point) in temperature of the valley (Fig. 4a) and the same year is identified as the year of abrupt decrease for precipitation (Fig. 4b).

4.3 Influence of North Atlantic Oscillation (NAO) ~~— index~~ on ~~and~~ ~~the~~ winter precipitation~~climate~~ic~~ fluctuations~~ over the Kashmir valley

Formatted: Font: (Default) Times New Roman, Complex Script Font: Times New Roman

The present study also investigate~~s~~d the tele-connection between the activity of North Atlantic Oscillation (NAO) and ~~index) with~~ the ~~temperature and precipitation~~ variations in temperature and precipitation over the Kashmir valley, particularly during winter season (December - March). It is found that~~The results indicate that~~ there is a significant negative/positive correlation (-0.54/0.68) between NAO (NAO index) and ~~has significant (S=0.05) negative correlation (-0.54) with winter~~ precipitation/~~while the winter~~ temperature ~~shows significant (0.01) positive correlation (0.68) with NAO~~ (Fig. 4c). This suggests that winter precipitation and temperature over the Kashmir

Formatted: Space After: 0 pt, Don't adjust space between Latin and Asian text, Don't adjust space between Asian text and numbers valley has a close associateion some association with the winter NAO index. Higher precipitation over Kashmir is associated with positive phase of NAO. Further the abrupt “change point” year, 1995, in the trend of temperature and precipitation coincides with that of the NAO indexfrom 1995 has clear association with abrupt variation in the NAO index. To test whether the trends in temperatures and precipitation over the Kashmir valley are forced by the NAO, regression analysis was performed on for temperatures and precipitation data during winter temperature and precipitation(December- March) which is depicted in the (Figs. 4e and f) and. the results indicate that there is a significant connection between NAO and precipitation over Kashmir. From the results it is clear that the observed trends in winter and spring temperature and precipitation would have been influenced by NAO.

The observed annual and seasonal variation of temperature at all the six stations except Qazigund (Gulmarg, Pahalgam, Kokarnag, Kupwara, Qazigund and Srinagar) is strongly correlated with WRF down-scaled simulations. Overall, tThe simulations show a good correlation of 0.66, 0.67, 0.72, 0.62, 0.79 and 0.47 for Srinagar, Gulmarg, Kokarnag, Kupwara, Pahalgam and Qazigund respectively. The annual mean simulated temperature shows very good correlation (0.85) with the observations. Figure 5 shows the annual and seasonal correlations of betweentemperature trends of observed and simulated temperatureswith the WRF model (location of Kokarnag is considered for WRF data) and observations.. However, the root mean square error (RMSE) analysis indicates shows that model simulations do slightly underestimate slighlty the observationsed values by with an average value of -0.43°C. Similar to Figure 5, Figure 6 shows the comparison between the WRF model simulated and observed precipitation. Even though the trend is similar, WRF model severely underestimates the rainfall amount. A detailed study on this topic will be presented in a separate paper. This issue needs to be addressed in our near future research studies.

4.4. Discussion

The Himalayan mountain system is quite sensitive to global climateic changevariations as the hydrology of the region is mainly dominated by snow and glaciers, making it one of the ideal sites for early detection of global warming (Solomon et al., 2007; Kohler and Maselli, 2009). Various reports claim that in the Himalayas significant warming had occurred in the last century (Fowler and Archer, 2006; Bhutiyani et al., 2007). Shrestha et al. (1999) analysed surface temperature at 49 stations located across the Nepal Himalayas and the results indicate warming trends in the range of 0.06 to 0.12°C per year. The observations of the present study are in agreement with the studies carried out by Shrestha et al. (1999), Archer and Fowler (2004) and Butiyani (2007). In the present study, it is observed that the rise in temperature is larger at higher altitude stations of Pahalgam (1.13°C) and Gulmarg (1.04°C) and it is about 0.9°C, 0.99°C, 0.04°C, and 0.10°C whereasfor the other stations, Kokarnag, Kupwara, Srinagar and Qazigund respectively recorded a rise of 0.9°C, 0.99°C, 0.04°C, and 0.10°C respectively with an average rise of 0.8°C during 1980-2016. Liu et al. (2009) and Liu and Chen (2000) also reported higher warming trends at higher altitudes in the Himalayan regions. Wiltshire (2013) warned, using a climate change model, that In

Formatted: Space After: 0 pt, Don't adjust space between Latin and Asian text, Don't adjust space between Asian text and numbers the future, t~~t~~he impacts of climate change ~~in the future~~ will be intense at higher elevations and in regions with complex topography, which is consistent with the model results of Wiltshore (2013).

The noteworthy observation in the present study is that ~~drastic and~~ statistically significant steep increase in the temperature (change point) occurred in the year~~has from~~ 1995 and it has been continuing therafter. The mega Elnino in 1998~~El Nino of 1998~~ has been considered ~~recorded in the history of the earth~~ as one of the strongest El-Nino's in history that led ~~brought~~ worldwide increase in temperature (Epstein et al., 1998). ~~In c~~Contrastingly, ~~during~~ the ~~1992~~Elnino in 1992~~,~~ led to a ~~the~~ decrease in temperature throughout the northern hemisphere, which is ascribed to the Mt. Pinatabu~~natural phenomena of~~ volcanic eruption ~~occurred on the Mt Pinatabu~~ (Swanson et al., 2009; IPCC, 2013). ~~This~~Also this event interrupted the direct sunlight to reach on the surface of the earth for about two months (Barnes et al., 2016).

Studies of trends in seasonal ~~-~~mean temperature in many regions across the Himalayas indicate higher warming trends in winter and spring months (Shrestha et al., 1999; Archer and Fowler, 2004; Butiyani, 2009). The seasonal difference found in the present study is consistent with other studies carried out for the Himalayas (Archer and Fowler, 2004; Sheikh et al., 2009 and Roe et al., 2003), Lancang Valley, China (Yunling and Yiping, 2005), Tibet (Liu and Chen, 2000) and the Swiss Alps (Beniston et al., 2010), where almost all stations recorded higher increase in the winter and spring temperatures comparing to autumn and summer temperatures. Recent studies found that reducing the extent depth of snow cover ~~snows~~ and shrinking glaciers may also be one of the contributing factors for the observed higher warming, as the~~because~~ reduction ~~in~~ in the percentage of snow and glacier can ~~change~~alter the surface albedo over ~~of~~ a~~the~~ region, which in turn can increase the surface air temperatures (Kulkarni et al., 2002; Groisman et al., 1994). Romshoo et al. (2015) and Murtaza and Romshoo (2016) have also reported that reduction of snow and glacier cover in the Kashmir regions of the Himalayas during the recent decades could be one of the reasons of occurrence of higher warming particularly on the higher elevated stations of Gulmarg and Pahalgam.

In the Himalayan mountain system, contrasting trends have been noted in precipitation over the recent decades (IPCC, 2001). Borgaonkar et al. (2001), Shreshtha et al. (2000) and Archer and Fowler (2004) observed increasing precipitation patterns over the Himalayas while Mooley and Parthasarathy (1983), Kumar and Jain (2009) and Demri and Dash (2012) reported large-scale decadal variation with increasing and decreasing precipitation periods. The results of the present study indicate that decrease in annual precipitation is slightly insignificant at all the six stations except the spring season. Increasing trend in temperature can trigger large-scale energy exchanges that become more intricate as complex topography alters the precipitation type and intensity in many ways (Kulkarni et al., 2002; Groisman et al., 1994).~~.~~ Climate model simulations (Zarenistana et al., 2014; Rashid et al., 2015) and empirical evidence (Vose et al., 2005; Romshoo et al., 2015) also confirm that increasing temperature results in increased water vapour leading to more intense precipitation events even when the total annual precipitation reduces slightly. The i~~I~~ncrease in temperature therefore enhances~~increases~~ the risks of both floods and

Formatted: Font: (Default) Times New Roman, 10 pt, Complex Script Font: Times New Roman, 10 pt

Formatted: Font: (Default) Times New Roman, 10 pt, Complex Script Font: Times New Roman, 10 pt

Formatted: Complex Script Font: 10 pt droughts. For example, the disaster flood event of September 2014 occurred in the Kashmir valley due to high frequency and high intense precipitation.

The North Atlantic Oscillation (NAO) is one of the strongest northern atmospheric weather phenomena ~~t~~occurring due ~~hat occur in the Northern hemisphere due to~~to the difference of atmospheric pressure at sea level between the Iceland low and ~~the~~ Azores high. It controls the strength and direction of westerly winds across the northern hemisphere. Surface temperatures have increased in the n~~N~~orthern h~~H~~emisphere in the past few decades (Mann et al., 1999; Jones et al., 2001Hijioka et al., 2014), and the rate of warming has been especially high (~ 0.15°C decade^{-1}) in the past 40 years (Folland et al., 2001; Hansen et al., 2001; Peters et al., 2013; Knutti et al., 2016). NAO causes substantial fluctuations in the climate of the Himalayas (Hurrell, 1997; Syed et al., 2006; Archer and Fowler, 2004). Several workers found a strong connection between the NAO and temperature and precipitation in the north-western Himalayas (Archer and Fowler, 2004; Bhutiyani et al., 2007; Bookhagen, 2010; Sharif et al., 2012; Iqbal and Kashif, 2013). A substantial fraction of the most recent warming is linked to the behaviour of the NAO (Hurrell, 1997; Thompson et al., 2003; Madhura et al., 2015). The climate of the Kashmir Himalayas is influenced by ~~the~~ western disturbances ~~particularly~~ in winter and spring seasons. Figs. 4c and d show correlation between ~~the~~ winter time NAO and ~~winter~~ temperature and precipitation over the Kashmir region. While temperature shows n~~N~~egative correlation of~~(~~-0.54~~)~~, precipitation shows ~~exists between winter temperature and winter NAO index and~~ positive correlation of ~~(~~0.68~~) for the precipitation~~. ~~Linear regression analysis was used to determine whether the variation in temperature and precipitation during the winter months (December-March) is forced by NAO.~~ From linear regression analyses, i~~I~~t is found that considerable variation in winter precipitation and / temperature over Kashmir is~~may be~~ forced by winter NAO. The weakening link~~effect~~ of NAO ~~particularly~~ after 1995 has a close association with decreased ~~the~~ winter precipitation and increased winter temperature in the valley. Similarly, Bhutiyani et al. (2009) and ~~–~~Dimri and Dash (2012) also found~~detected a~~ statistically significant ~~substantial~~ decreasing trend in ~~the~~ precipitation ~~pattern and identified considerable decrease in winter precipitation~~ which they related to weakening of NAO index. However, for establishing a detailed mechanism incorporating ~~involved in~~ these variations requires thorough investigation.

The ~~comparison of~~ WRF model simulations compare well with ~~the~~ observations~~ed stations data shows a~~ (significantly strong correlation of 0.85) and the correlation is~~. It is also found that~~ ~~the~~ more for~~higher elevated~~ elevated stations than ~~show higher correlation than~~ ~~the lower elevated~~ valley stations of Srinagar and Kupwara. ~~;~~ H~~h~~owever, it is expected that the good correlation can~~ould~~ result if more precise terrain information is incorporated in the WRF model simulations. Earlier~~Various researchers~~ studies (e.g. Kain and Fritsch, 1990, 1993; Kain, 2004) also found good correlation between observed and WRF simulated rainfall events. In conjunction with large-scale features such as ~~the~~ NAO and ENSO, it can result in large~~-~~scale variability in the climate of this region (Ogura and Yoshizaku, 1988). Furthermore, incorporation of mesoscale teleconnections and their associations in the WRF model can further help in understanding large-scale weather forecasting ~~particularly in~~over this region.

4.5. Physical mechanisms of climate and weather of Jammu &Kashmir

Large-scale spatial and temporal variations in the meridional winds could be due to the passage of planetary-scale Rossby waves (RW) in the atmospheric winds. When RWs break in the upper troposphere, it could lead to vertical transport of atmospheric air between the upper troposphere and lower stratosphere and an irreversible horizontal transport of air mass between the subtropics and extra tropics (McIntyre and Palmer, 1983). Rossby waves have the characteristic of remaining coherent over many days and propagat~~eing~~ long distances of the order of synoptic to planetary scales leading to tele-connection of remote atmospheres of global extent. ~~It is clear from~~ T~~t~~he study~~ies~~ by Chang and Yu (1999) indicates that during northern winter months of December–January–February, Rossby wave packets can be most coherent over a large distance of from the northern Africa to the Pacific through the southern Asia. There are reports on extreme weather events connected to Rossby waves of synoptic to planetary scales in the upper troposphere (e.g. Screen and Simmonds, 2014). In northern~~the northern parts of~~ India, there is an increasing trend in heavy rainfall events, particularly over the Himachal Pradesh, Uttrakhand and Jammu and Kashmir (Sinha Ray and Srivastava, 2000; Nibanupudi et al., 2015). Long-scale Rossby waves can lead to ~~the~~ generation of alternating convergence and divergence in the upper troposphere that in turn can affect surface weather parameters like precipitation through generation of instabilities in the atmospheric air associated with convergence and divergence (Niranjankumar et al., 2016).

Using observations and MERRA (Modern-Era Retrospective Analysis for Research and Applications reanalysis data; http://gmao.gsfc.nasa.gov/research/merra/), Rienecker et al. (2011) showed ~~a~~ strong correlation between 6-10 day periodic oscillations associated with Rossby waves in the upper tropospheric winds ~~associated with Rossby waves~~ and surface weather parameters like atmospheric pressure, winds, temperature, relative humidity and rainfall during a severe weather event observed at the Indian extratropical station, Nainital (29.45° N, 79.5° E), in~~during~~ November–December 2011. ~~Further~~ T~~t~~hey also note~~d~~ that when the upper troposphere shows divergence, the lower troposphere shows convergence and as a result more moisture gets accumulated there leading to enhancement of relative humidity and hence precipitation. It was asserted that Rossby waves in the upper troposphere can lead to surface weather related events through the action of convergence or divergence in the atmospheric air. It is to be noted that a passing Rossby wave can cause fluctuations in divergence and convergence in the atmosphere at periodicities (typically 6-10 days, 12-20 days) corresponding to the Rossby waves at a particular site.

It was reported that Rossby waves account for more than 30% of monthly mean precipitation and more than 60% of surface temperature over many extra tropical regions and influence short~~-~~term ~~climatic~~ extreme weather phenomena~~s~~ (Schubert et al., 2011). Planetary waves affecting weather events severely for long duration of the order of months have been reported by many researchers (Petoukhov et al., 2013; Screen and Simmonds, 2014; Coumou et al., 2014). Screen and Simmonds (2014) found that in the mid latitudes~~, regions~~ there was~~is~~ a strong association between enhanced Rossby wave activity, surface temperature and extreme precipitation events in~~during~~ 1979–2012. Since slowly propagating Rossby waves can influence weather at a particular site for long periods lasting more than few weeks, it is can be seen~~one can see~~ the imprint of climatic variations of Rossby waves in weather events from monthly mean atmospheric parameters.

To understand the present observation of different precipitation characteristics over different stations~~at all the six mentioned stations over the study area~~, it is ~~we~~ compared ~~the~~ between monthly variation of PV in the upper troposphere and ~~with~~ precipitation~~s at all these stations~~. Potential vorticity at 350K~~ potential temperature (PT)~~ surface is identified ~~as a valuable information~~ for investigating ~~the activity of~~ Rossby waves as their~~its~~ breakage (can be identified through reversal of gradient in PV) at this level can lead to exchange of air at the boundary between the tropics and extra tropics (Homeyer and Bowman, 2013). Similarly PV at 200 hPa pressure surface~~ (PS)~~ is more appropriate for identifying Rossby wave breaking in the subtropical regions (Garfinkel and Waugh, 2014).

Since the Srinagar city is located on comparatively plain land than the other ~~, among the~~ all six stations~~, is onthe plain land with comparatively less topographical features located in the centre~~ of the Kashmir valley, precipitation ~~here~~ associated with western disturbances here is under the direct influence of planetary-scale Rossby waves. Accordingly, correlation between PV at the 350 K~~ PT~~ (located near the core of the subtropical jet, Homeyer and Bowman, 2013) and 200 hPa pressure surfaces and precipitation is found significantly larger over Srinagar than other stations. ~~and the correlation becomes weaker for the other stations located at higher altitudes due to significant orographic influences.~~ Orographic effects at other stations can have significant influence on planetary Rossby waves. Therefore~~As a result~~, ~~one can see that~~ PV (ERA-Interim data, Dee et al., 2011) in the upper troposphere varies in accordance with precipitation, which is clearly depicted in Fig. 7, during the entire years of 1984, 1987, 1988, 1990, 1993, 1994, 1995, 1996, 1999, 2006 and 2009. In general, it is ~~One can~~ observed that sometimes PV at 350K ~~PT~~ surface and at other times at 200 hPa pressure surface follows precipitation. This would be due to the influence of Rossby waves generated due to baroclinic or and barotropic instabilities~~ respectively~~. Particularly, the correlation between PV (sometimes either one or both) and precipitation is significantly positive during the Indian summer monsoon months of June-September for ~~of~~ all the years from 1980 to 2009 except 1983, 1985, 1989, 2000-2005 and 2009. At present it is not known why this relation became weak during1999-2010.

For Kokarnag (Fig. 8), the topography of which is similar to Srinagar but it is located in the vicinity of high mountains, the relation between PV and precipitation particularly during the Indian summer-monsoon~~ period~~ is almost similar to that of Srinagar during 1983, 1985, 1989, 1991, 1998, 1999, 2000-2005.~~, but in 2009 it became poor~~. Th~~eis~~ deterioration of the link between PV and rainfall over Kokarnag and Srinagar~~particularly~~ during 1999-2010 ~~is really due to the effect of climate change, which is similar to what was observed for Srinagar. It~~ is intriguing and it may be associated with climate change.~~that why this relation became poor during the years of 1999-2010.~~ In the northern Kashmir region of Kupwara (Fig. 9), msl higher by ~1 km than Srinagar, the relation between PV and precipitation is good in the years 1982-1983, 1985-1988, 1990-1994, 1995-1996, 1999, and 2006. Similar to

Srinagar and Kokarnag, Kupwara also shows a poor link during 1999-2010. Particularly during the summer monsoon period, the PV-precipitation relation is good in all the years except 1989, 1998, 2000-2005, and 2009. One interesting observation is that in 1983, 1985 and 1991 ~~shows better~~the ~~-~~correlation between PV and precipitation for Kupwara is better than Srinagar and Kokarnag. Since Kupwara is located near elevated Greater Himalayan mountain range, Rossby waves associated with topography would have contributed to the good correlation between PV and precipitation here, which is not the case for Srinagar and Kokarnag. In the case of Pahalgam, (Fig.10), located near the Greater Himalayas, generally the link between PV and precipitation is good in almost all the years 1980-2016 but with a difference that sometimes both the PVs and on other times only either of them follow precipitation. ~~during some months.~~ Particularly during summer monsoon months, similar to Kupwara, these years 1989, 2000-2003, 2005 and 2009 show poor correlation. ~~From~~ In general, ~~the~~ precipitation ~~present observations, it can be easily ascertained that stations located~~ near the Greater Himalayas is significantly ~~show~~ ~~similar characteristics~~ influenced~~d~~ ~~by topography associated~~ by Rossby waves associated with topography.

For the hilly station of Qazigund (Fig. 11), located in the south Kashmir region (above ~3 km ~~height~~ msl) near the foot hills of Pir Panjal mountain range, the relation between PV and precipitation ~~ship~~ is better than that of~~observed over~~ the northern station Kupwara. For example, in 1988, the relation is much better over Qazigund than Kupwara. However the opposite is true in 1987. Interestingly, in 1985, both Kupwara and Qazigund show similar variation in PV and precipitation. This may be due to the effect of the nature of limited equator-ward propagation of Rossby waves from mid~~-~~latitudes. In 1995, 1997 and 1998, PV and precipitation follow similar time variation at~~for~~ both Kupwara and Qazigund except for ~~three months of~~ January-March during which precipitation over Qazigund but not Kupwara follows PV. Interestingly, in the whole year of 1999, precipitation at both the stations, ~~Kupwara and Quazigund,~~ follows exceedingly well with PV; however in 1998, only Qazigund but not Kupwara shows good relation. In 2009, precipitation does not follow PV for both the stations. Interestingly in all the months of 2006, PV follows well with precipitation for both Kupwara and Qazigund. However in September, Kupwara but not Qazigund shows good relation. In 2004, only PV at ~~constant potential temperature surface (~~350K~~)~~ surface follows well with precipitation for both the stations. For the summer monsoon period of June-September, these years ~~do not show good correlation~~, namely, 1983, 1985, 1989, 1990, 2000-2003, 2005, 2007-2009, do not show good correlation, which is almost similar to Srinagar and Kokarnag.

In the case of Gulmarg (Fig. 12), PV and precipitation follow each other well in the years of 1988, 1993, 1994 and 1995. In 1996, during the Indian summer monsoon period of June-September, only PV at 350K~~constant potential temperature~~ surface follows precipitation. Overall, during the summer monsoon period, the relationship between PV and precipitation is appreciable for all the years except for 1983, 1989, 1990, 1999 and 2000-2009, which is almost similar to Kupwara and Pahalgam. It may be noted that these stations are located near relatively~~comparatively~~ elevated mountains and hence topographically induced Rossby waves could have contributed to this good relation. ~~From~~ T~~t~~he observations suggest~~-~~ ~~of these stations, one can come to the conclusion easily~~ that high altitude mountains affect the precipitation characteristics through topography generated Rossby waves. The interesting finding here is that irrespective of the different heights of mountains, all the stations show that during 1999-2010 the correlation between upper tropospheric PV and surface precipitation~~rainfall~~ found to be~~became~~ poor, indicating that some unknown new atmospheric dynamical concepts would have played significant role in disturbing the precipitation characteristics significantly over the western Himalayan region. This issue needs to be addressed in the near future by invoking suitable theoretical models so that predictability of extreme weather events can be improved in the mountainous Himalaya.

During 2011-2016 (Fig. 13), it may be observed that for Gulmarg the link~~linkage~~ between PV~~potential vorticities~~ and precipitation holds ~~is~~good ~~–~~in general~~–good~~ for all these years except around July 2012, July-December 2013 and 2015. It is interesting to note here that during the historical flood event of September 2014, the PV~~potential vorticities~~ and precipitation follow each other but in the preceding and following years of 2013 and 2015 their ~~–~~linkage ~~between PV and precipitation~~ is ~~rather~~ poor as noted earlier. Similarly, all the other stations (Srinagar, Pahalgam, Kokarnag, Kupwara, and Qazigund) also show that the link between PV and precipitation is good around September 2014. This would indicate clearly that the extreme weather event occurred during September 2014 is due to~~over the area occurred because of the~~ intense large-scale Rossby wave activity rather than~~and not because of~~ any localized adverse atmospheric thermodynamical conditions such as ~~like enhanced~~ local convection~~ etc~~. In Srinagar, most of the times PV and precipitation follow each other very well as observed during January 2011-June 2012, January-July of 2013 & 2014, whole 2015 and 2016. In Qazigund, this relation is good only during January-July and September-October 2014, during the entire 2015 and 2016 (similar to Srinagar). For Kupwara, PV follows precipitation well during whole of 2011, January-July 2012, January-May 2013, January-November 2014, whole of 2015 and 2016. In the case of Kokarnag, good relation is observed during March-August 2012, January-June 2013 and 2014, around September 2014. In contrast, the relationship is very poor in the entire years of 2015 and 2016. Pahalgam interestingly shows good correlation between PV and precipitation during the whole years of 2011 and 2012. In 2013, 2014, 2015 and 2016, it is good only during January-June in addition to exceptionally good in~~near~~ September 2014.

Finally, it may be observed that the ERA-interim reanalysis data of meridional wind velocity (12UT) at ~3 km altitude above the mean seal level show alternating positive (southerly) and negative values, resembling the atmospheric Rossby waves in the sub~~-~~tropical region during 1-6 September 2014 (Fig. 14)~~,~~. The meridional winds associated with Rossby waves could be easily noted to have their extensions in both the Arabian Sea and Bay of Bengal, indicating that water vapour from both the regions was transported~~attracted~~ towards the Jammu and Kashmir, India region as the converging point of Rossby waves was located near this region. It may be easily noticed that the waves got strengthened on 4thand weakened on 5th and ultimately dissipated on 6th September. This dissipation of Rossby waves led to ~~the~~ dumping of the transported~~attracted~~ water vapour over this region thus caused ~~leading to~~ the historical-record heavy-flooding during this period. This is one clear example of how synoptic scale Rossby waves can reorganize water vapour over large scale and lead to extreme rainfall event. It is well known that subtropical westerly jet is one of many important sources of Rossby waves in the mid to tropical latitudes. If the subtropical jet drifts climatically northward then the surface weather events associated with them also will drift similarly, ~~which will~~ leading to unusual weather changes climatically.

~~Interestingly from the published reports, it can be found~~Published reports Barnes and Polvani, 2013; Lu et al., 2014) indicate ~~-~~that ~~there is a close association between~~ long-term variations ~~changes~~ in Rossby wave breaking activities and stratospheric dynamics have close association with global climate change.~~events and climatic variations and variations in the stratospheric dynamics~~ (~~Barnes and Polvani 2013; Lu et al. 2014).Climatic m~~Merdional shift of the center of subtropical jets, arising due to~~which is in response to the~~ enhanced polar vortex and upper-tropospheric baroclinicity are possible due to the consequences of ~~arising due to~~ global warming, ~~of the tropospheric jet~~ has been successfully linked to climatic changes in Rossby wave breaking events caused by baroclinic instabilities (Wittman et al., 2007; Kunz et al., 2009; Rivière, 2011; Wilcox et al., 2012). The ~~climatic~~ long-term increase in the tropospheric warming arising due to baroclinic forcing of Rossby waves is more prominent in the mid-latitudes than in the tropical regions (Allen et al., 2012; Tandon et al., 2013). This mid-latitude warming plays a criticaln ~~important~~ role in driving ~~the~~ poleward shift of ~~poleward~~the subtropical ~~-~~jet ~~shift~~ responding to climate change (Ceppi et al., 2014). It is to be remembered that the combined effect~~action~~ of tropospheric baroclinic forcing (warming) and stratospheric polar vortex can gradually move the subtropical jet from about 27° to 54° (Garfinkel and Waugh, 2014). Using Global circulation models (GCM), linear wave theory predicts that in response to increased greenhouse gas (GHG) forcing, mid-latitude eddy-driven jets, arising due to strong coupling between synoptic scale eddy activity and jet streams in both the hemispheres, will be ~~climatically~~ shifted poleward (Fourth report of Intergovernmental Panel on Climate Change (IV-IPCC), Meehl et al., 2007). However, mid-latitude Rossby waves and the associated wave dissipation in the subtropical region are predicted to move climatologically~~ically~~ towards equator~~ward~~ due to the spherical geometry of the Earth (Hoskins et al., 1977; Edmon et al., 1980). This propagation of location of wave breaking towards the equator will have long-term (climatic) impact on ~~the proper~~ relation between variations in upper tropospheric~~e~~ PV ~~variations~~ associated with Rossby waves and ~~the associated~~ surface precipitation~~weather parameters~~ in the subtropical latitude regions. This may be one of the reasons that during 1999-2010, the relation between PV and precipitation became poor as observed in the present study.

Regarding surface temperature, except for its linear long-~~-~~term trend, there is no clear evidence of strong link between variations in the upper tropospheric potential vorticities and surface temperature for all the six stations mentioned. It seems that long-term (climatic) variations in the upper tropospheric vorticities have significantly less influence on surface temperature variations.

5. Conclusions

In this study, trends and variations in ~~Studies of climatic change in the~~ surface temperature and precipitation over the Jammu and Kashmir, India region of the western Himalayas are carried out for a period of 37 years during 1980-2016. Analyses of the observations reveal that ~~an increase in the~~ the annual temperature increased by 0.8°C during this period. Higher ~~i~~increase in annual temperature accompanied by insignificant decrease in annual precipitation is noted for stations located at higher altitudes. ~~and that is accompanied by an insignificant decrease in annual precipitation.~~ Long-term variation of winter temperature and precipitation has good correlation with winter NAO index. ~~Additionally,~~ To provide more conclusive evidence on our observations, we employed WRF model simulations which show good correlation of 0.85 with the observed data. It is found that in the recent decades, precipitation associated with both the monsoons and western disturbances has been decreasing significantly. While the monsoon deficiency is associated with decreasing difference in surface temperature between the Indian landmass and nearby Indian Ocean, the deficiency associated with western disturbances during winter is due to the climatic northward displacement of the subtropical westerly jet. This subtropical jet wind helps to enhance the moisture transport~~to drag moisture~~ associated with disturbances from the tropical Atlantic Ocean, Mediterranean and Caspian Seas to the Himalayan region. Regarding historical extreme weather event associated with September 2014 floods in Jammu and Kashmir, it is found that breaking of intense Rossby wave activity over Kashmir played an important role as the wave could transport~~drag~~ lots of water vapor from both the Bay of Bengal and Arabian Sea and dump them here through its breaking during the first week of September, 2014, leading to the extreme rainfall event measuring more than 620 mm in southern ~~some~~ parts of the ~~South~~ Kashmir.

Acknowledgements:

Thanks are due to the India Meteorological Department, Pune, India, ERA-Interim reanalyses and WRF model simulation teams for the data of meteorological parameters employed in the present work. Prof. Shakil Romshoo and Dr. Sumaira Zaz gratefully acknowledge the support of the Department of Science and Technology (DST), Government of India under the research project titled "Himalayan Cryosphere: Science and Society". Dr. T. K. Ramkumar and Dr. V. Yesubabu acknowledge the support of Dept. of Space, Govt. ofIndia.The authors express gratitude to the two anonymous reviewers and Editor for their valuable comments and suggestions on the earlier version of the manuscript that has greatly improved its content and structure.

Table 2 Annual and seasonal Precipitation trends in Kashmir valley during 1980-2016

Table 3: Mean temperature increase at each station from during 1980-2016.

Stations	Elevation in meters	Topography	Increase annual temperature in °C
Pahalgam	2600mts	Located on mountain top	1.13
Gulmarg	2740mts	Located on mountain top	1.04
Srinagar	1600mts	Located on plane surface in an urbanized area	0.55
Kupwara	1670mts	Located on plane surface bounded on	0.92

		three sides by mountains	
Kokarnag	2000mts	Located on plane surface	0.99
Qazigund	1650mts	Located on plane surface	0.78

Figure captions:

Fig. 1 Geographical setting of the Kashmir valley (b) inside the Jammu and Kashmir state (a) of India (c) along with marked locations of six meteorological observation stations: Srinagar, Gulmarg, Pahalgam, Kokarnag, Qazigund and Kupwara

Fig. 2(a-g) Trends in surface temperature (°C) at the six interested locations of the Kashmir valley (a) for annual mean temperature, (b) maximum temperature, (c) minimum temperature, (d) winter mean temperature during December-February, (e) spring mean temperature (March-May), (f) summer mean temperature (June-August) and (g) autumn mean temperature (September-November).

Fig. 3(a-e) Same as Fig. 2 but for precipitation (mm) and only for means of (a) annual, (b) winter, (c) spring, (d) summer and (e) autumn.

Fig. 4(a) Cumulative testing for defining change point of temperature (averaged for all the six stations of the Kashmir valley), (b) same as (a) but for precipitation, (c) comparison of trends of Kashmir temperature with North Atlantic Ocean (NAO index (d) same as (c) but for precipitation, (e) regression analysis of winter temperature and (f) regression analysis of winter precipitation.

Fig. 5 (a) Comparision between observed and WRF model (location of Kokarnag is considered) simulated annually averaged temperature (averaged for all the stations) variations for the years 1980-2016, (b) same as (a) but for spring season, (c) for summer, (d) for autumn, (e) winter, (f) for minimum temperature and (g) maximum temperature

Fig. 6. Same as Fig. 5 but for precipitation. Here the minimum and maximum precipitation are not considered because it cannot be defined them properly in a day.

Fig. 7 (a-f) Observed monthly-averaged surface temperature and precipitation and ERA-interim potential vorticities at the 350 K potential temperature and 200 hPa level pressure surfaces for the station, Srinagar during the years 1980-2016.

Fig. 8 (a-f) Same as the Fig. 6 but for Kokarnag.

Fig. 9 (a-f) Same as the Fig. 7 but for Kupwara.

Fig. 10 (a-f) Same as the Fig. 8 but for Pahalgam.

Fig. 11 (a-f) Same as the Fig. 9 but for Qazigund.

Fig. 12 (a-f) Same as the Fig. 10 but for Gulmarg.

Fig. 13 (a-f) Same as the Fig. 11 but for all the stations and during the years 2011-2016.

Fig. 14. (a-f) Synopitc scale ERA-interim meridional wind velocity covering the Jammu and Kashmir region for sis days from 01 to 06 September 2014 (historical record flooding rainfall over this region).
