17     **Abstract**

19     Local weather and climate of the Himalayas are sensitive and interlinked with global scale changes in  
20     climate as the hydrology of this region is mainly governed by snow and glaciers. There are clear and strong  
21     indicators of climate change reported for the Himalayas, particularly the Jammu and Kashmir region situated in the  
22     western Himalayas. In this study, using observational data, detailed characteristics of long- and short-term as well as  
23     localized variations of temperature and precipitation are analysed for these six meteorological stations, namely,  
24     Gulmarg, Pahalgam, Kokarnag, Qazigund, Kupwara and Srinagar of Jammu and Kashmir, India during 1980-2016.  
25     In addition to analysis of stations observations, we also utilized the dynamical downscaled simulations of WRF  
26     model and ERA-Interim (ERA-I) data for the study period. The annual and seasonal temperature and precipitation  
27     changes were analysed by carrying out Student's t-test, Mann-Kendall, Linear regression and Cumulative deviation  
28     statistical tests. The results show an increase of 0.8°C in average annual temperature over thirty seven years (from  
29     1980 to 2016) with higher increase in maximum temperature (0.97°C) compared to minimum temperature (0.76°C).  
30     Analyses of annual mean temperature at all the stations reveal that the high-altitude stations of Pahalgam (1.13°C)  
31     and Gulmarg (1.04°C) exhibit a steep increase and statistical significant trends. Precipitation patterns in the valley  
32     such as at Gulmarg and Pahalgam show a slight and definite decrease in the annual rainfall at Gulmarg and  
33     Pahalgam stations. Seasonal analyses show significant increasing trends in the winter and spring temperatures at all  
34     stations with prominent decrease in spring precipitation.. The present study also reveals that variation in temperature  
35     and precipitation during winter (December - March) has a close association with the North Atlantic Oscillation  
36     (NAO). Further, the observed temperature data (monthly averaged data for 1980-2016) at all the stations show good  
37     correlation of 0.86 with the results of WRF and therefore the model downscaled simulations are considered as a  
38     valid scientific tool for the studies of climate change in this region. Though the correlation between WRF model and

39 observed precipitation is significantly strong, the WRF model underestimates significantly the rainfall amount,  
40 which necessitates the need for the sensitivity study of the model using the various microphysical parameterization  
41 schemes. The potential vorticities in the upper troposphere troposphere are obtained from ERA-I over the Jammu  
42 and Kashmir region indicate that the extreme weather event of September 2014 occurred due to breaking of intense  
43 atmospheric Rossby wave activity over Kashmir. As the wave could transport a large amount of water vapour from  
44 both the Bay of Bengal and Arabian Sea and dump them over the Kashmir region through wave breaking, it is  
45 probably resulted in the historical devastating flooding of the whole Kashmir valley in the first week of September  
46 2014. This was accompanied by extreme rainfall events measuring more than 620 mm in some parts of the Pir  
47 Panjal range in the South Kashmir.  
48

## 49 1. Introduction

50

51 Climate change is a real Earth's atmospheric and surface phenomenon and the influences of which on all  
52 spheres of life are considered significant almost everywhere in the world in the past few decades. Extreme weather  
53 events like anomalously large floods and unusual drought conditions associated with changes in climate play havoc  
54 with livelihoods of even established civilizations particularly in the coastal and high-mountainous areas. Jammu and  
55 Kashmir, India, located in the Western Himalayan region, is one such cataclysmic mountainous region where  
56 significant influence of climate change on local weather has been observed for the last few decades; (1) shrinking  
57 and reducing glaciers, (2) devastating floods, (3) decreasing winter duration and rainfall, and (4) increasing summer  
58 duration and temperature (Solomon et al., 2007; Kohler and Maselli, 2009; Immerzeel et al., 2010; Romshoo et al.,  
59 2015; Romshoo et al., 2017). Western disturbances (WD) is considered as one of the main sources of winter  
60 precipitation for the Jammu and Kashmir region, which brings water vapour mainly from the tropical Atlantic  
61 Ocean, Mediterranean Sea, Caspian Sea and Black sea. Though WD is perennial, it is most intense during northern  
62 winter (December-February; Demri et al., 2015). Planetary-scale atmospheric Rossby-waves have potential to  
63 significantly alter the distribution and movement of WD according to their intensity and duration (few to tens of  
64 days). Since WD is controlled by planetary-scale Rossby waves in the whole troposphere of the subtropical region,  
65 diagnosing different kinds of precipitation characteristics is easier with the help of potential vorticity (PV) at 350K  
66 potential temperature (PT) and 200 hPa level pressure surface (PS) as they are considered as proxies for Rossby  
67 wave activities (Ertel, 1942; Bartels et al., 1998; Demri et al., 2015 and Hunt et al 2018a). Here onwards, it will be  
68 simply called PV at 350 K and 200 hPa surfaces. For example, (Postel and Hitchman, 1999; Hunt 2018b) studied the  
69 characteristics of Rossby wave breaking (RWB) events occurring at 350K surface transecting the subtropical  
70 westerly jets. Similarly, Waugh and Polvani (2000) studied RWB characteristics at 350K surface in the Pacific  
71 region during northern fall–spring with emphasis on their influence on westerly ducts and their intrusion into the  
72 tropics. Since PV is a conserved quantity on isentropic and isobaric surfaces (ISOES & ISOBS) when there is no  
73 exchange of heat and pressure respectively, it is widely used for investigating large-scale dynamical processes  
74 associated with frictionless and adiabatic flows. Moreover, all other dynamical parameters, under a given suitable

75 balanced-atmospheric-background condition, can be derived from PV and boundary conditions (Hoskins et al.,  
76 1985).

77  
78 Divergence of the atmospheric air flows near the upper troposphere is larger during precipitation, leading to  
79 increase in the strength of PV. Because of which, generally there will be a good positive correlation between  
80 variations in the strength of PV in the upper troposphere and precipitation over the ground provided that the  
81 precipitation is mainly due to the passage of large-scale atmospheric weather systems like western disturbances, and  
82 monsoons. Wind flows over topography can significantly affect the vertical distribution of water vapour and  
83 precipitation characteristics. Because of this, positive correlation between variations in PV and precipitation can be  
84 modified significantly.. These facts need to be taken into account while finding long-term variations of precipitation  
85 near mountainous regions like the western Himalaya. The interplay between the flow of western disturbances and  
86 topography of the western Himalaya complicates further the identification of source mechanisms of extreme weather  
87 events (Das et al., 2002; Shekhar et al., 2010) like the ones that occurred in the western Himalayan region; Kashmir  
88 floods in 2014 and Leh floods in 2010 in the Jammu and Kashmir region and Uttrakhand floods in 2013. Kumar et  
89 al. (2015) also noted that major flood events in the Himalayas are related to changing precipitation intensity in the  
90 region. This necessitates making use of proper surrogate parameters like PV and distinguish between different  
91 source mechanisms of extreme weather events associated with both the long-term climatic impacts of remote origin  
92 and short-term localized ones like organized convection (Romatschke and Houze 2011; Rasmussen and Houze  
93 2012; Houze and Rasmussen 2016; Martius et al., 2012).

94  
95 The main aim of the present study is to investigate long-term (climate) variation of surface temperature and  
96 precipitation over the Jammu and Kashmir, India region of the western Himalayas in terms of of its connections with  
97 NAO and atmospheric Rossby wave activity in the upper troposphere. Since PV is considered as a measure of  
98 Rossby wave activity, the present work analyses in detail, for a period of 37 years during 1980-2016, monthly  
99 variation of PV (ERA-interim reanalysis data, Dee et al., 2001) in the upper troposphere (at 350 K and 200 hPa  
100 surfaces ) and compares it with observed surface temperature and rainfall (India Meteorological Department, IMD)  
101 at six widely separated mountainous locations with variable orographic features (Srinagar, Gulmarg, Pahalgam,  
102 Qazigund, Kokarnag and Kupwara). There exist several reports on climatological variation of meteorological  
103 parameters in various parts of the Himalayas. For example, Kumar and Jain (2009) and Bhutiyani et al. (2010) found  
104 an increase in the temperature in the north-western Himalayas with significant variations in precipitation patterns.  
105 Archer and Fowler (2004) examined temperature data of seven stations in the Karakoram and Hindu Kush  
106 Mountains of the Upper Indus River Basin (UIRB) in search of seasonal and annual trends using statistical test like  
107 regression analysis. Their results revealed that mean winter maximum-temperature has increased significantly while  
108 mean summer minimum-temperature declined consistently. On the contrary, Lui et al. (2009) examined long-term  
109 trends in minimum and maximum temperatures over the Tibetan mountain range during1961-2003 and found that  
110 minimum temperature increases faster than maximum temperature in all the months. Romshoo et al. (2015)  
111 observed changes in snow precipitation and snow-melt-runoff in the Kashmir valley and attributed the observed

112 depletion of stream flow to the changing climate in the region. Bolch et al. (2012) reported that the glacier extent in  
113 the Karakoram range is increasing.

114

115 These contrasting findings of long-term variations in temperature and precipitation in the Himalayas need  
116 to be verified by analyzing long-term climatological data available in the region. However, the sparse and scanty  
117 availability of regional climate data pose challenges in understanding the complex microclimate in this region.  
118 Therefore, studying the relationship of recorded regional (Jammu and Kashmir) climatic variations in temperature  
119 and precipitation with remote and large-scale weather phenomena such as the North Atlantic Oscillation (NAO), and  
120 El Niño Southern Oscillation (ENSO) is necessary for understanding the physical processes that control the locally  
121 observed variations (Ghashmi, 2015). Archer and Fowler (2004) and Iqbal and Kashif (2013) found that large-scale  
122 atmospheric circulation like NAO influences significantly the climate of the Himalayas. However, detailed  
123 information about variation in temperature and precipitation and its teleconnection with observed variations of NAO  
124 is inadequately available for this part of the Himalayan region (Kashmir Valley).

125

## 126 **2. Geographical setting of Kashmir**

127

128 The inter mountainous valley of Kashmir has a unique geographical setting and it is located between the  
129 Greater Himalayas in the north and Pir Panjal ranges in the south, roughly within the latitude and longitude ranges  
130 of  $33^{\circ} 55'$  to  $34^{\circ} 50'$  and  $74^{\circ} 30'$  to  $75^{\circ} 35'$  respectively (Fig.1). The heights of these mountains range from about  
131 3,000 to 5,000 m and the mountains strongly influence the weather and climate of the region. Generally the  
132 topographic setting of the six stations, though variable, could be broadly categorized into two; (1) stations located on  
133 plains (Srinagar, Kokarnag, Qazigund and even Kupwara) and (2) those located in the mountain setting (Gulmarg,  
134 Pahalgam). Physiographically, the valley of Kashmir is divided into three regions; Jhelum valley floor, Greater  
135 Himalayas and Pir Panjal. In order to represent all the regions of the valley, six meteorological stations located  
136 widely with different mean sea levels (msl), namely, Gulmarg (2740m), Pahalgam (2600m), Kokarnag (2000m),  
137 Srinagar (1600m), Kupwara (1670m) and Qazigund (1650m) were selected for analyses of observed weather  
138 parameters.

139

140 The Kashmir valley is one of the important watersheds of the upper Indus basin harbouring more than 105 glaciers  
141 and it experiences the Mediterranean type of climate with marked seasonality (Romshoo and Rashid, 2014).  
142 Broadly, four seasons (Khattak et al 2011; Rashid et al., 2015) are defined for the Kashmir valley; winter (December  
143 to February), spring (March to May), summer (June to August), and autumn (September to November). It is to be  
144 clarified here that while defining the period of NAO (Fig. 4) it is considered December-March as winter months as  
145 defined by Archer and Fowler (2004) and Iqbal and Kashif (2013) and in all other parts of the manuscript it is  
146 December-February as per the IMD definition. The annual temperature in the valley varies from about  $-10^{\circ}\text{C}$  to  
147  $35^{\circ}\text{C}$ . The rainfall pattern in the valley is dominated by winter time precipitation associated with western

148 disturbances (Dar et al., 2014) while the snow precipitation is received mainly in winter and early spring season  
149 (Kaul and Qadri, 1979).

150

151 **2. Data and Methodology**

152

153 India Meteorological Department (IMD) provided 37 years (1980-2016) of data of daily precipitation,  
154 maximum and minimum temperatures for all the six stations. Monthly averaged data were further analysed to find  
155 long-term variations of weather parameters. Statistical tests including Mann-Kendall, Spearman Rho, Cumulative  
156 deviation, Student's t-test were performed to determine long term-trends and turning point of weather parameters  
157 with statistical significances. Similar analyses and tests were performed also for the Weather and Research  
158 Forecasting (WRF) model simulated and ERA-Interim reanalyses data ( $0.75^{\circ}$  by  $0.75^{\circ}$  spatial resolution in the  
159 horizontal plane, monthly averaged time resolution) of same weather parameters and for the NAO index. Brief  
160 information about these data sets is provided below.

161

162 **3.1 Measurements and model simulations**

163

164 The obtained observational data are analysed carefully for homogeneity and missing values. Analyses of  
165 ratios of temperature from the neighbouring stations with the Srinagar station were conducted using relative  
166 homogeneity test (WMO, 1970). It is found that there is no significant inhomogeneity and data gap for any station.  
167 Few missing data points were linearly interpolated and enough care was taken not to make any meaningful  
168 interpretation during such short periods of data gaps in the observations. Annual and seasonal means of temperature  
169 and precipitation were calculated for all the stations and years. To compute seasonal means, the data were divided  
170 into the following seasons: winter (December to February), spring (March to May), summer (June to August) and  
171 autumn (September to November). Trends in the annual and seasonal means of temperature and precipitation were  
172 determined using Mann-Kendall (non-parametric test) and linear regression tests (parametric test) at the confidence  
173 levels of  $S = 99\%$  or (0.01),  $S = 95\%$  or 0.05 and  $S = 90\%$  or 0.1. These tests have been extensively used in hydro  
174 meteorological data analyses as they are less sensitive to heterogeneity of data distribution and least affected by  
175 extreme values or outliers in data series. Various methods have been applied to determine change points of a time  
176 series (Radziejewski et al., 2000; Chen and Gupta, 2012). In this study, change point in time series of temperature  
177 and precipitation was identified using cumulative deviation test and Student's t test (Pettitt, 1979). This method  
178 detects the time of significant change in the mean of a time series when the exact time of the change is unknown  
179 (Gao et al., 2011).

180

181 Winter NAO index during 1980–2010 were obtained for further analyses from Climatic Research Unit  
182 through the web link <https://www.cru.uea.ac.uk/data>. The winter (December - March) NAO index is based on

183 difference of normalized sea level pressure (SLP) between Lisbon, Portugal and Iceland, which is available from  
184 1964 onwards. Positive NAO index is associated with stronger-than-average westerlies over the middle latitudes  
185 (Hurrell, 1997). Correlation between mean (December-March) temperature, precipitation and NAO index was  
186 determined using Pearson correlation coefficient method. To test whether the observed trends in winter temperature  
187 and precipitation are enforced by NAO, linear regression analysis (forecast) was performed (Fig. 4e and f). The  
188 following algorithm calculates or predicts a future value by using existing values. The predicted value is a y-value  
189 for a given w-value. The known values are existing w-values and y-values, and the new value is predicted by using  
190 linear regression.

191  
192 The syntax is as follows  
193

194 FORECAST(x, known\_y's, known\_w's)

195 W is the data point for which we want to predict a value.

196 Known\_y's is the dependent array or range of data (rainfall or temperature).

197 Known\_w's is the independent array or range of data (time).

198  
199 The equation for FORECAST is  $a + bw$ , where:

200 
$$a = \hat{y} - b\hat{w} \quad \text{and } b = \sum(w - \hat{w})(y - \hat{y}) / \sum(w - \hat{w})^2$$

201

202 and where  $\hat{w}$  and  $\hat{y}$  are the sample means AVERAGE (known\_w's) and AVERAGE (known\_y's).

203

204

### 205 3.2. WRF Model configuration

206  
207 The Advanced Research WRF version 3.9.1 model simulation was used in this study to downscale the ERA-Interim  
208 (European Centre for Medium Range Weather Forecasting Re Analysis) data over the Indian Monsoon region. The  
209 model is configured with 2 two-way nested domains (18 km and 9-km horizontal resolutions), 51 vertical levels and  
210 model top at 10 hPa level. The model first domain extends from longitude from 24.8516 E to 115.148E and latitude  
211 from 22.1127S to 46.7629 N while the second domain covers the longitudes from 56.3838E to 98.5722E and  
212 latitudes from 3.86047 S to 38.2874 N.

213

214

215 The initial and boundary conditions supplied to WRF model are obtained from ERA-Interim 6-hourly data.  
216 Model physics used in the study for boundary layer processes is Yonsei University's non-local diffusion scheme  
217 (Hong et al., 2006), the Kain-Fritsch scheme for cumulus convection (Kain and Fritsch, 1993), Thomson scheme for  
218 microphysical processes, the Noah land surface scheme (Chen and Dudhia, 2001) for surface processes, Rapid

219 Radiation Transfer Model (RRTM) for long-wave radiation (Mlawer et al., 1997), and the Dudhia (1989) scheme for  
220 short-wave radiation. The physics options configured in this study are adopted based on the previous studies of  
221 heavy rainfall and Monsoon studies over the Indian region (Srinivas et al., 2013, Madala et al., 2016, Ghosh et al.,  
222 2016; Srinivas et al., 2018).

223

224 For the present study, the WRF model is initialized on daily basis at 12 UTC using ERA-Interim data and  
225 integrated for a 36-hour period using the continuous re-initialization method (Lo et al., 2008; Langodan, et al., 2016;  
226 and Viswanadhapalli et al., 2017). Keeping the first 12-hours as model spin-up time, the remaining 24-hour daily  
227 simulations of the model are merged to get the data during 1980-2016. To find out the skill of the model, the  
228 downscaled simulations of WRF model are validated for six IMD surface meteorological stations. The statistical  
229 skill scores such as bias, mean error (ME) and root mean square error (RMS) were computed for the simulated  
230 temperature against the observed temperature data of IMD.

231

## 232 **4. Results and Discussion:**

233

### 234 **4.1. Trend in annual and seasonal temperature**

235

236 Tables 1& 2 show the results of statistical tests (Mann-Kendall and linear regression, cumulative deviation and  
237 Student's t) carried out on the temperature and precipitation data respectively. All the parametric and nonparametric  
238 tests carried out for the trend analysis and abrupt changes in the trend showed almost similar results. Table 1,  
239 therefore shows results of representative tests where higher values of statistical significance between Mann-  
240 Kendall/linear regression test and Cumulative deviation/student's t test are considered. It is evident that there is an  
241 increasing trend at different confidence levels in annual and seasonal temperatures of all the six stations (Pahalgam,  
242 Gulmarg, Kokarnag, Srinagar, Kupwara and Qazigund), located in different topographical settings (Table 3). During  
243 1980-2016, Pahalgam and Gulmarg, located at higher elevations of about 2500m amsl (above mean sea level),  
244 registered statistically significant increase in average annual temperature by 1.13°C and 1.04°C (Fig. 2a). It is to be  
245 noted that hereafter it will not be mentioned explicitly about the period 1980-2016 and statistically significant means  
246 the confidence level is about 90%. Kokarnag and Kupwara, located at the heights of about 1800-2000m amsl,  
247 showed an increase of 0.9°C and 1°C respectively (Fig. 2a). However, Srinagar and Qazigund, located at the  
248 heights of about 1700m-1600m amsl, exhibited an increase of 0.65°C and 0.44°C (Fig. 2a).

249

250 Analyses of maximum and minimum temperatures (Table 1 and Fig. 2b) for the six stations reveal higher rate  
251 increase in maximum temperature. Pahalgam and Kupwara recorded the highest rise of ~1.3°C followed by  
252 Kokarnag (1.2°C) and Srinagar (1.1°C). The exception is that Gulmarg and Qazigund (being a hilly station) shows  
253 less than 0.6°C in maximum temperature. The minimum temperature exhibits a lowest increase of 0.3°C at Srinagar

254 and highest increase at Gulmarg station of 1.2°C(Fig. 2c). Analyses of composite seasonal mean of minimum and  
255 maximum temperatures in the valley reveal higher increase in maximum temperature in winter and spring seasons.  
256 Among four stations (Gulmarg, Pahalgam, Kokarnag and Kupwara), Gulmarg indicates an increase of less than 1°C  
257 while Pahalgam, Kokarnag and Kupwara shows an increase of 0.9°C, 0.9°C and less than 0.9°C respectively  
258 (Table 1 and Fig. 2d). On the contrary, Qazigund and Srinagar showed a slight increase of less than 0.4°C and 0.5°C  
259 respectively. Mean spring-temperature shows higher rise comparing to other seasons temperatures for all the  
260 stations. Gulmarg shows an increase of less than 1.4°C. Pahalgam, Kupwara, Kokarnag showed increase of 1.3°C  
261 at  $S = 0.01$ . Qazigund and Srinagar revealed 0.6°C and 1°C increase respectively as shown in the Table 1 and Fig.  
262 2e. In summer, the temperature rise for Pahalgam is about less than 0.6°C and for Gulmarg and Qazigund, it is about  
263 0.4°C and 0.2°C respectively(Table 1). Kupwara, Kokarnag and Srinagar reveal an increase of less than 0.3°C,  
264 0.4°C and 0.1°C respectively (Fig. 2f). In Autumn, Gulmarg shows an increase of 0.9°C and Pahalgam exhibit less  
265 than 0.6°C. On the contrary Qazigund shows less than 0.4°C at while Srinagar shows no significant increase in  
266 observed temperatures (Fig. 2g and Table 1).

267

## 268 **4.2 Trend in annual and seasonal precipitation**

269

270 The annual precipitation pattern of the valley is comparable to that of temperature with higher decrease  
271 observed at the upper elevation stations of Gulmarg and Pahalgam (Fig. 3a and Table 2). Similar to temperature,  
272 Table 2 provides in detail the test results of Mann-Kendall, linear regression and Student's t. While Kokarnag and  
273 Kupwara show significant decrease, the lower elevated stations, Qazigund and Srinagar, exhibit insignificant  
274 decrease (Fig. 3a). Winter precipitation decrease is maximum at Gulmarg and Kokarnag followed by Kupwara and  
275 Pahalgam and it is insignificant decrease for Srinagar and Qazigund (Table 2 and Fig. 3b). The spring season  
276 precipitation exhibits decreasing trend for all the six stations with the lowest decrease of 42mm precipitation at  
277 Kupwara (Table 2).

278

279 During summer months also, precipitation shows decreasing trend for all stations except Qazigund that it is  
280 statistically insignificant (Fig. 3d, and Table 2). For Qazigund there is no apparent trend in summer precipitation.  
281 The autumn precipitation also shows insignificant decreasing trend for the stations (Fig. 3e and Table 2).  
282 Cumulative test was used to determine the “change point” of trend in the annual and seasonal variations of  
283 temperature and precipitation. Results reveal that the year 1995 is the year of abrupt increase (change point) in  
284 temperature of the valley (Fig. 4a) and the same year is identified as the year of abrupt decrease for precipitation  
285 (Fig. 4b).

286

287

288 **4.3 Influence of North Atlantic Oscillation (NAO) on the winter precipitation over the**  
289 **Kashmir valley**

290

291 The present study also investigates the tele-connection between the activity of North Atlantic Oscillation  
292 (NAO) and the variations in temperature and precipitation over the Kashmir valley, particularly during winter  
293 season (December - March). It is found that there is a significant negative/positive correlation (-0.54/0.68) between  
294 NAO (NAO index) and precipitation/temperature (Fig. 4c). This suggests that winter precipitation and temperature  
295 over the Kashmir valley has a close association with the winter NAO. Higher precipitation over Kashmir is  
296 associated with positive phase of NAO. Further the “change point” year, 1995, in the trend of temperature and  
297 precipitation coincides with that of the NAO index. To test whether the trends in temperatures and precipitation over  
298 the Kashmir valley are forced by the NAO, regression analysis was performed on winter temperature and  
299 precipitation (Figs. 4e and f) and the results indicate that there is a significant connection between NAO and  
300 precipitation over Kashmir,

301

302 The observed annual and seasonal variation of temperature at all stations except Qazigund is strongly  
303 correlated with WRF downscaled simulations. Overall, the simulations show correlation of 0.66, 0.67, 0.72, 0.62,  
304 0.79 and 0.47 for Srinagar, Gulmarg, Kokarnag, Kupwara, Pahalgam and Qazigund respectively. The annual mean  
305 simulated temperature shows very good correlation (0.85) with observations. Figure 5 shows annual and seasonal  
306 correlations between trends of observed and simulated temperatures (location of Kokarnag is considered for WRF  
307 data). However, root mean square error (RMSE) analysis indicates that model simulations underestimate slightly  
308 the observations by an average value of -0.43°C. Similar to Figure 5, Figure 6 shows the comparison between WRF  
309 model simulated and observed precipitation. Even though the trend is similar, WRF model severely underestimates  
310 the rainfall amount. A detailed study on this topic will be presented in a separate paper.

311

312 **4.4. Discussion**

313

314 The Himalayan mountain system is quite sensitive to global climate change as the hydrology of the region  
315 is mainly dominated by snow and glaciers, making it one of the ideal sites for early detection of global warming  
316 (Solomon et al., 2007; Kohler and Maselli, 2009). Various reports claim that in the Himalayas significant warming  
317 had occurred in the last century (Fowler and Archer, 2006; Bhutiyani et al., 2007). Shrestha et al. (1999) analysed  
318 surface temperature at 49 stations located across the Nepal Himalayas and the results indicate warming trends in the  
319 range of 0.06 to 0.12°C per year. The observations of the present study are in agreement with the studies carried out  
320 by Shrestha et al. (1999), Archer and Fowler (2004) and Butiyani (2007). In the present study, it is observed that rise  
321 in temperature is larger at higher altitude stations of Pahalgam (1.13°C) and Gulmarg (1.04°C) and it is about 0.9°C,  
322 0.99°C, 0.04°C, and 0.10°C for the other stations, Kokarnag, Kupwara, Srinagar and Qazigund respectively during

323 1980-2016. Liu et al. (2009) and Liu and Chen (2000) also report higher warming trends at higher altitudes in the  
324 Himalayan regions. In the future, the impacts of climate change will be intense at higher elevations and in regions  
325 with complex topography, which is consistent with the model results of Wiltshire (2013).

326  
327 The noteworthy observation in the present study is that statistically significant steep increase in the  
328 temperature (change point) occurred in the year 1995 and it has been continuing thereafter. The mega El Nino in  
329 1998 has been considered as one of the strongest El-Nino's in history that led worldwide increase in temperature  
330 (Epstein et al., 1998). Contrastingly, the El Nino in 1992 led to a decrease in temperature throughout the northern  
331 hemisphere, which is ascribed to the Mt. Pinatubo volcanic eruption (Swanson et al., 2009; IPCC, 2013). Also this  
332 event interrupted the direct sunlight to reach on the surface of the earth for about two months (Barnes et al., 2016).

333  
334 Studies of trends in seasonal-mean temperature in many regions across the Himalayas indicate higher  
335 warming trends in winter and spring months (Shrestha et al., 1999; Archer and Fowler, 2004; Butiyani, 2009). The  
336 seasonal difference found in the present study is consistent with other studies carried out for the Himalayas (Archer  
337 and Fowler, 2004; Sheikh et al., 2009 and Roe et al., 2003), Lancang Valley, China (Yunling and Yiping, 2005),  
338 Tibet (Liu and Chen, 2000) and the Swiss Alps (Beniston et al., 2010), where almost all stations recorded higher  
339 increase in the winter and spring temperatures comparing to autumn and summer temperatures. Recent studies found  
340 that reducing the extent depth of snow cover and shrinking glaciers may also be one of the contributing factors for  
341 the observed higher warming, as the reduction in the percentage of snow and glacier can alter the surface albedo  
342 over a region, which in turn can increase the surface air temperatures (Kulkarni et al., 2002; Groisman et al., 1994).  
343 Romshoo et al. (2015) and Murtaza and Romshoo (2016) have also reported that reduction of snow and glacier  
344 cover in the Kashmir regions of the Himalayas during the recent decades could be one of the reasons of occurrence  
345 of higher warming particularly on the higher elevated stations of Gulmarg and Pahalgam.

346  
347 In the Himalayan mountain system, contrasting trends have been noted in precipitation over the recent  
348 decades (IPCC, 2001). Borgaonkar et al. (2001), Shrestha et al. (2000) and Archer and Fowler (2004) observed  
349 increasing precipitation patterns over the Himalayas while Mooley and Parthasarathy (1983), Kumar and Jain (2009)  
350 and Demri and Dash (2012) reported large-scale decadal variation with increasing and decreasing precipitation  
351 periods. The results of the present study indicate that decrease in annual precipitation is slightly insignificant at all  
352 the six stations except the spring season. Increasing trend in temperature can trigger large-scale energy exchanges  
353 that become more intricate as complex topography alters the precipitation type and intensity in many ways  
354 (Kulkarni et al., 2002; Groisman et al., 1994). Climate model simulations (Zarenistana et al., 2014; Rashid et al.,  
355 2015) and empirical evidence (Vose et al., 2005; Romshoo et al., 2015) also confirm that increasing temperature  
356 results in increased water vapour leading to more intense precipitation events even when the total annual  
357 precipitation reduces slightly. The increase in temperature therefore enhances the risks of both floods and droughts.  
358 For example, the disaster flood event of September 2014 occurred in the Kashmir valley due to high frequency and  
359 high intense precipitation.

360        The North Atlantic Oscillation (NAO) is one of the strongest northern atmospheric weather phenomena  
361 occurring due to the difference of atmospheric pressure at sea level between the Iceland low and Azores high. It  
362 controls the strength and direction of westerly winds across the northern hemisphere. Surface temperatures have  
363 increased in the northern hemisphere in the past few decades (Mann et al., 1999; Jones et al., 2001; Hijioka et al.,  
364 2014), and the rate of warming has been especially high ( $\sim 0.15^{\circ}\text{C decade}^{-1}$ ) in the past 40 years (Folland et al.,  
365 2001; Hansen et al., 2001; Peters et al., 2013; Knutti et al., 2016). NAO causes substantial fluctuations in the climate  
366 of the Himalayas (Hurrell, 1997; Syed et al., 2006; Archer and Fowler, 2004). Several workers found a strong  
367 connection between the NAO and temperature and precipitation in the north-western Himalayas (Archer and Fowler,  
368 2004; Bhutiyani et al., 2007; Bookhagen, 2010; Sharif et al., 2012; Iqbal and Kashif, 2013). A substantial fraction of  
369 the most recent warming is linked to the behaviour of the NAO (Hurrell, 1997; Thompson et al., 2003; Madhura et  
370 al., 2015). The climate of the Kashmir Himalayas is influenced by western disturbances in winter and spring  
371 seasons. Figs. 4c and d show correlation between winter time NAO and temperature and precipitation over the  
372 Kashmir region. While temperature shows negative correlation of -0.54, precipitation shows positive correlation of  
373 0.68. From linear regression analyses, it is found that considerable variation in winter precipitation and temperature  
374 over Kashmir is forced by winter NAO. The weakening link of NAO after 1995 has a close association with  
375 decreased winter precipitation and increased winter temperature in the valley. Similarly, Bhutiyani et al. (2009) and  
376 Dimri and Dash (2012) also found statistically significant decreasing trend in precipitation which they related to  
377 weakening of NAO index. However, for establishing a detailed mechanism incorporating these variations requires  
378 thorough investigation.

379

380        The WRF model simulations compare well with observations (significantly strong correlation of 0.85) and  
381 the correlation is more fore elevated stations than valley stations of Srinagar and Kupwara. However, it is expected  
382 that the good correlation can result if more precise terrain information is incorporated in the WRF model  
383 simulations. Earlier studies (e.g. Kain and Fritsch, 1990, 1993; Kain, 2004) also found good correlation between  
384 observed and WRF simulated rainfall events. In conjunction with large-scale features such as NAO and ENSO, it  
385 can result in large-scale variability in the climate of this region (Ogura and Yoshizaku, 1988). Furthermore,  
386 incorporation of mesoscale teleconnections and their associations in the WRF model can further help in  
387 understanding large-scale weather forecasting over this region.

388

389

#### 390        **4.5. Physical mechanisms of climate and weather of Jammu & Kashmir**

391

392        Large-scale spatial and temporal variations in the meridional winds could be due to the passage of  
393 planetary-scale Rossby waves (RW) in the atmospheric winds. When RWs break in the upper troposphere, it could  
394 lead to vertical transport of atmospheric air between the upper troposphere and lower stratosphere and an  
395 irreversible horizontal transport of air mass between the subtropics and extra tropics (McIntyre and Palmer, 1983).

396 Rossby waves have the characteristic of remaining coherent over many days and propagate long distances of the  
397 order of synoptic to planetary scales leading to tele-connection of remote atmospheres of global extent. The study  
398 by Chang and Yu (1999) indicates that during northern winter months of December–January–February, Rossby  
399 wave packets can be most coherent over a large distance of from the northern Africa to the Pacific through the  
400 southern Asia. There are reports on extreme weather events connected to Rossby waves of synoptic to planetary  
401 scales in the upper troposphere (e.g. Screen and Simmonds, 2014). In northern India, there is an increasing trend in  
402 heavy rainfall events, particularly over the Himachal Pradesh, Uttrakhand and Jammu and Kashmir (Sinha Ray and  
403 Srivastava, 2000; Nibanupudi et al., 2015). Long-scale Rossby waves can lead to generation of alternating  
404 convergence and divergence in the upper troposphere that in turn can affect surface weather parameters like  
405 precipitation through generation of instabilities in the atmospheric air associated with convergence and divergence  
406 (Niranjan Kumar et al., 2016).

407

408 Using observations and MERRA (Modern-Era Retrospective Analysis for Research and Applications  
409 reanalysis data; <http://gmao.gsfc.nasa.gov/research/merra/>), Rienecker et al. (2011) showed strong correlation  
410 between 6-10 day periodic oscillations associated with Rossby waves in the upper tropospheric winds and surface  
411 weather parameters like atmospheric pressure, winds, temperature, relative humidity and rainfall during a severe  
412 weather event observed at the Indian extratropical station, Nainital (29.45° N, 79.5° E), in November–December  
413 2011. They also note that when the upper troposphere shows divergence, the lower troposphere shows convergence  
414 and as a result more moisture gets accumulated there leading to enhancement of relative humidity and hence  
415 precipitation. It was asserted that Rossby waves in the upper troposphere can lead to surface weather related events  
416 through the action of convergence or divergence in the atmospheric air. It is to be noted that a passing Rossby wave  
417 can cause fluctuations in divergence and convergence in the atmosphere at periodicities (typically 6-10 days, 12-20  
418 days) corresponding to the Rossby waves at a particular site.

419

420 It was reported that Rossby waves account for more than 30% of monthly mean precipitation and more than  
421 60% of surface temperature over many extra tropical regions and influence short-term extreme weather phenomena  
422 (Schubert et al., 2011). Planetary waves affecting weather events severely for long duration of the order of months  
423 have been reported by many researchers (Petoukhov et al., 2013; Screen and Simmonds, 2014; Coumou et al.,  
424 2014). Screen and Simmonds (2014) found that in the mid latitudes, there was a strong association between  
425 enhanced Rossby wave activity, surface temperature and extreme precipitation events in 1979–2012. Since slowly  
426 propagating Rossby waves can influence weather at a particular site for long periods lasting more than few weeks, it  
427 is can be seen the imprint of climatic variations of Rossby waves in weather events from monthly mean atmospheric  
428 parameters.

429

430 To understand the present observation of different precipitation characteristics over different stations, it is  
431 compared between monthly variation of PV in the upper troposphere and precipitation. Potential vorticity at 350K  
432 surface is identified for investigating Rossby waves as their breakage (can be identified through reversal of

433 gradient in PV) at this level can lead to exchange of air at the boundary between the tropics and extra tropics  
434 (Homeyer and Bowman, 2013). Similarly PV at 200 hPa pressure surface is more appropriate for identifying Rossby  
435 wave breaking in the subtropical regions (Garfinkel and Waugh, 2014).

436

437 Since the Srinagar city is located on comparatively plain land than the other all six stations of the Kashmir  
438 valley, precipitation associated with western disturbances here is under the direct influence of planetary-scale  
439 Rossby waves. Accordingly, correlation between PV at the 350 K (located near the core of the subtropical jet,  
440 Homeyer and Bowman, 2013) and 200 hPa pressure surfaces and precipitation is found significantly larger over  
441 Srinagar than other stations. Orographic effects at other stations can have significant influence on planetary Rossby  
442 waves. Therefore, PV (ERA-Interim data, Dee et al., 2011) in the upper troposphere varies in accordance with  
443 precipitation, which is clearly depicted in Fig. 7, during the entire years of 1984, 1987, 1988, 1990, 1993, 1994,  
444 1995, 1996, 1999, 2006 and 2009. In general, it is observed that sometimes PV at 350K surface and at other times at  
445 200 hPa pressure surface follows precipitation. This would be due to the influence of Rossby waves generated due to  
446 baroclinic or and barotropic instabilities. Particularly, the correlation between PV (sometimes either one or both) and  
447 precipitation is significantly positive during the Indian summer monsoon months of June-September for all the years  
448 from 1980 to 2009 except 1983, 1985, 1989, 2000-2005 and 2009. At present it is not known why this relation  
449 became weak during 1999-2010.

450

451 For Kokarnag (Fig. 8), the topography of which is similar to Srinagar but it is located in the vicinity of high  
452 mountains, the relation between PV and precipitation particularly during the Indian summer-monsoon is almost  
453 similar to that of Srinagar during 1983, 1985, 1989, 1991, 1998, 1999, 2000-2005.. The deterioration of the link  
454 between PV and rainfall over Kokarnag and Srinagar during 1999-2010 is intriguing and it may be associated with  
455 climate change. In the northern Kashmir region of Kupwara (Fig. 9), msl higher by ~1 km than Srinagar, the relation  
456 between PV and precipitation is good in the years 1982-1983, 1985-1988, 1990-1994, 1995-1996, 1999, and 2006.  
457 Similar to Srinagar and Kokarnag, Kupwara also shows a poor link during 1999-2010. Particularly during the  
458 summer monsoon period, the PV-precipitation relation is good in all the years except 1989, 1998, 2000-2005, and  
459 2009. One interesting observation is that in 1983, 1985 and 1991 the correlation between PV and precipitation for  
460 Kupwara is better than Srinagar and Kokarnag. Since Kupwara is located near elevated Greater Himalayan mountain  
461 range, Rossby waves associated with topography would have contributed to the good correlation between PV and  
462 precipitation here, which is not the case for Srinagar and Kokarnag. In the case of Pahalgam, (Fig.10), located near  
463 the Greater Himalayas, generally the link between PV and precipitation is good in almost all the years 1980-2016  
464 but with a difference that sometimes both the PVs and on other times only either of them follow precipitation.  
465 Particularly during summer monsoon months, similar to Kupwara, these years 1989, 2000-2003, 2005 and 2009  
466 show poor correlation. In general, precipitation near the Greater Himalayas is significantly influenced by Rossby  
467 waves associated with topography.

468

469 For the hilly station of Qazigund (Fig. 11), located in the south Kashmir region (above ~3 km msl) near the  
470 foot hills of Pir Panjal mountain range, the relation between PV and precipitation is better than that of the northern  
471 station Kupwara. For example, in 1988, the relation is much better over Qazigund than Kupwara. However the  
472 opposite is true in 1987. Interestingly, in 1985, both Kupwara and Qazigund show similar variation in PV and  
473 precipitation. This may be due to the effect of the nature of limited equatorward propagation of Rossby waves from  
474 mid-latitudes. In 1995, 1997 and 1998, PV and precipitation follow similar time variation at both Kupwara and  
475 Qazigund except for January-March during which precipitation over Qazigund but not Kupwara follows PV.  
476 Interestingly, in the whole year of 1999, precipitation at both the stations, follows exceedingly well with PV;  
477 however in 1998, only Qazigund but not Kupwara shows good relation. In 2009, precipitation does not follow PV  
478 for both the stations. Interestingly in all the months of 2006, PV follows well with precipitation for both Kupwara  
479 and Qazigund. However in September, Kupwara but not Qazigund shows good relation. In 2004, only PV at 350K  
480 surface follows well with precipitation for both the stations. For the summer monsoon period of June-September,  
481 these years, namely, 1983, 1985, 1989, 1990, 2000-2003, 2005, 2007-2009, do not show good correlation, which is  
482 almost similar to Srinagar and Kokarnag.

483

484 In the case of Gulmarg (Fig. 12), PV and precipitation follow each other well in the years of 1988, 1993,  
485 1994 and 1995. In 1996, during the Indian summer monsoon period of June-September, only PV at 350K surface  
486 follows precipitation. Overall, during the summer monsoon period, the relationship between PV and precipitation is  
487 appreciable for all the years except for 1983, 1989, 1990, 1999 and 2000-2009, which is almost similar to Kupwara  
488 and Pahalgam. It may be noted that these stations are located near relatively elevated mountains and hence  
489 topographically induced Rossby waves could have contributed to this good relation. The observations suggest that  
490 high altitude mountains affect the precipitation characteristics through topography generated Rossby waves. The  
491 interesting finding here is that irrespective of the different heights of mountains, all the stations show that during  
492 1999-2010 the correlation between upper tropospheric PV and surface precipitation found to be poor, indicating that  
493 some unknown new atmospheric dynamical concepts would have played significant role in disturbing the  
494 precipitation characteristics significantly over the western Himalayan region. This issue needs to be addressed in the  
495 near future by invoking suitable theoretical models so that predictability of extreme weather events can be improved  
496 in the mountainous Himalaya.

497

498 During 2011-2016 (Fig. 13), it may be observed that for Gulmarg the link between PV and precipitation  
499 holds good in general for all these years except around July 2012, July-December 2013 and 2015. It is interesting to  
500 note here that during the historical flood event of September 2014, the PV and precipitation follow each other but in  
501 the preceding and following years of 2013 and 2015 their linkage is poor as noted earlier. Similarly, all the other  
502 stations (Srinagar, Pahalgam, Kokarnag, Kupwara, and Qazigund) also show that the link between PV and  
503 precipitation is good around September 2014. This would indicate clearly that the extreme weather event occurred  
504 during September 2014 is due to intense large-scale Rossby wave activity rather than any localized adverse  
505 atmospheric thermodynamical conditions such as local convection. In Srinagar, most of the times PV and

506 precipitation follow each other very well as observed during January 2011-June 2012, January-July of 2013 & 2014,  
507 whole 2015 and 2016. In Qazigund, this relation is good only during January-July and September-October 2014,  
508 during the entire 2015 and 2016 (similar to Srinagar). For Kupwara, PV follows precipitation well during whole of  
509 2011, January-July 2012, January-May 2013, January-November 2014, whole of 2015 and 2016. In the case of  
510 Kokarnag, good relation is observed during March-August 2012, January-June 2013 and 2014, around September  
511 2014. In contrast, the relationship is very poor in the entire years of 2015 and 2016. Pahalgam interestingly shows  
512 good correlation between PV and precipitation during the whole years of 2011 and 2012. In 2013, 2014, 2015 and  
513 2016, it is good only during January-June in addition to exceptionally good in September 2014.

514

515 Finally, it may be observed that the ERA-interim reanalysis data of meridional wind velocity (12UT) at ~3  
516 km altitude above the mean seal level show alternating positive (southerly) and negative values, resembling the  
517 atmospheric Rossby waves in the subtropical region during 1-6 September 2014 (Fig. 14). The meridional winds  
518 associated with Rossby waves could be easily noted to have their extensions in both the Arabian Sea and Bay of  
519 Bengal, indicating that water vapour from both the regions was transported towards the Jammu and Kashmir, India  
520 region as the converging point of Rossby waves was located near this region. It may be easily noticed that the waves  
521 got strengthened on 4<sup>th</sup> and weakened on 5<sup>th</sup> and ultimately dissipated on 6<sup>th</sup> September. This dissipation of Rossby  
522 waves led to dumping of the transported water vapour over this region thus caused the historical-record heavy-  
523 flooding during this period. This is one clear example of how synoptic scale Rossby waves can reorganize water  
524 vapour over large scale and lead to extreme rainfall event. It is well known that subtropical westerly jet is one of  
525 many important sources of Rossby waves in the mid to tropical latitudes. If the subtropical jet drifts climatically  
526 northward then the surface weather events associated with them also will drift similarly, leading to unusual weather  
527 changes climatically.

528

529 Published reports Barnes and Polvani, 2013; Lu et al., 2014) indicate that long-term variations in Rossby  
530 wave breaking activities and stratospheric dynamics have close association with global climate change. (Meridional  
531 shift of the center of subtropical jets, arising due to enhanced polar vortex and upper-tropospheric baroclinicity are  
532 possible due to the consequences of global warming, has been successfully linked to climatic changes in Rossby  
533 wave breaking events caused by baroclinic instabilities (Wittman et al., 2007; Kunz et al., 2009; Rivière, 2011;  
534 Wilcox et al., 2012). The long-term increase in the tropospheric warming arising due to baroclinic forcing of Rossby  
535 waves is more prominent in the mid-latitudes than in the tropical regions (Allen et al., 2012; Tandon et al., 2013).  
536 This mid-latitude warming plays a critical role in driving poleward shift of the subtropical jet responding to climate  
537 change (Ceppi et al., 2014). It is to be remembered that the combined effect of tropospheric baroclinic forcing  
538 (warming) and stratospheric polar vortex can gradually move the subtropical jet from about 27° to 54° (Garfinkel  
539 and Waugh, 2014). Using Global circulation models (GCM), linear wave theory predicts that in response to  
540 increased greenhouse gas (GHG) forcing, mid-latitude eddy-driven jets, arising due to strong coupling between  
541 synoptic scale eddy activity and jet streams in both the hemispheres, will be shifted poleward (Fourth report of  
542 Intergovernmental Panel on Climate Change (IV-IPCC), Meehl et al., 2007). However, mid-latitude Rossby waves

543 and the associated wave dissipation in the subtropical region are predicted to move climatologically towards equator  
544 due to the spherical geometry of the Earth (Hoskins et al., 1977; Edmon et al., 1980). This propagation of location of  
545 wave breaking towards the equator will have long-term (climatic) impact on relation between variations in upper  
546 tropospheric PV associated with Rossby waves and surface precipitation in the subtropical latitude regions. This  
547 may be one of the reasons that during 1999-2010, the relation between PV and precipitation became poor as  
548 observed in the present study.

549

550         Regarding surface temperature, except for its linear long-term trend, there is no clear evidence of strong  
551 link between variations in the upper tropospheric potential vorticities and surface temperature for all the six stations  
552 mentioned. It seems that long-term (climatic) variations in the upper tropospheric vorticities have significantly less  
553 influence on surface temperature variations.

554

555

## 556         **5. Conclusions**

557

558

559         In this study, trends and variations in surface temperature and precipitation over the Jammu and  
560 Kashmir, India region of the western Himalayas are carried out for a period of 37 years during 1980-2016. Analyses  
561 of the observations reveal that the annual temperature increased by 0.8°C during this period. Higher increase in  
562 annual temperature accompanied by insignificant decrease in annual precipitation is noted for stations located at  
563 higher altitudes. Long-term variation of winter temperature and precipitation has good correlation with winter NAO  
564 index. To provide more conclusive evidence on our observations, we employed WRF model simulations which  
565 show good correlation of 0.85 with the observed data. It is found that in the recent decades, precipitation associated  
566 with both the monsoons and western disturbances has been decreasing significantly. While the monsoon deficiency  
567 is associated with decreasing difference in surface temperature between the Indian landmass and nearby Indian  
568 Ocean, the deficiency associated with western disturbances during winter is due to the climatic northward  
569 displacement of the subtropical westerly jet. This subtropical jet wind helps to enhance the moisture transport  
570 associated with disturbances from the tropical Atlantic Ocean, Mediterranean and Caspian Seas to the Himalayan  
571 region. Regarding historical extreme weather event associated with September 2014 floods in Jammu and Kashmir,  
572 it is found that breaking of intense Rossby wave activity over Kashmir played an important role as the wave could  
573 transport lots of water vapor from both the Bay of Bengal and Arabian Sea and dump them here through its breaking  
574 during the first week of September, 2014, leading to the extreme rainfall event measuring more than 620 mm in  
575 southern parts of the Kashmir.

576

579 **Acknowledgements:**

580  
581 Thanks are due to the India Meteorological Department, Pune, India, ERA-Interim reanalyses and WRF model  
582 simulation teams for the data of meteorological parameters employed in the present work. Prof. Shakil Romshoo and  
583 Dr. Sumaira Zaz gratefully acknowledge the support of the Department of Science and Technology (DST),  
584 Government of India under the research project titled “Himalayan Cryosphere: Science and Society”. Dr. T. K.  
585 Ramkumar and Dr. V. Yesubabu acknowledge the support of Dept. of Space, Govt. of India. The authors express  
586 gratitude to the two anonymous reviewers and Editor for their valuable comments and suggestions on the earlier  
587 version of the manuscript that has greatly improved its content and structure.
