I can't find the scientific significance and academic value of this article. Why study Up-Vis at 0.1, 0.3, 0.5 km? The authors have not pointed out the differences of Up-Vis at the three altitudes, nor have they studied the differences between them and the horizontal visibility on the ground. What is the purpose of using Up-Vis at three high altitudes? There are many detailed studies focusing on the relationship between visibility, relative humidity and other meteorological elements and PM_{2.5}. The study method and conclusions of this article are too simple and general comparing with the related works.
