12
13 **Abstract.** An Ensemble Kalman Filter data assimilation (DA) system has been
14 developed to improve air quality forecasts using surface measurements of PM₁₀, PM_{2.5},
15 SO₂, NO₂, O₃ and CO together with an online regional chemical transport model, WRF-
16 Chem (Weather Research and Forecasting with Chemistry). This DA system was
17 applied to simultaneously adjust the chemical initial conditions (ICs) and emission
18 inputs of the species affecting PM₁₀, PM_{2.5}, SO₂, NO₂, O₃ and CO concentrations during
19 an extreme haze episode that occurred in early October 2014 over the East Asia.
20 Numerical experimental results indicate that ICs play key roles in PM_{2.5}, PM₁₀ and CO
21 forecasts during the severe haze episode over the North China Plain. The 72-h
22 verification forecasts with the optimized ICs and emissions performed very similarly to
23 the verification forecasts with only optimized ICs and the prescribed emissions. For the
24 first-day forecast, near perfect verification forecasts results were achieved. However,
25 with longer range forecasts, the DA impacts decayed quickly. For the SO₂ verification
26 forecasts, it was efficient to improve the SO₂ forecast via the joint adjustment of SO₂
27 ICs and emissions. Large improvements were achieved for SO₂ forecasts with both the
28 optimized ICs and emissions for the whole 72-h forecast range. Similar improvements
29 were achieved for SO₂ forecasts with optimized ICs only for just the first 3 h, and then

30 the impact of the ICs decayed quickly. For the NO₂ verification forecasts, both forecasts
31 performed much worse than the control run without DA. Plus, the 72-h O₃ verification
32 forecasts performed worse than the control run during the daytime, due to the worse
33 performance of the NO₂ forecasts, even though they performed better at night. However,
34 relatively favorable NO₂ and O₃ forecast results were achieved for the Yangtze River
35 delta and Pearl River delta regions.

36

37 **1 Introduction**

38 Predicting and simulating air quality remains a challenge in heavily polluted regions
39 (Wang et al., 2014; Ding et al. 2016). Chemical data assimilation (DA), which
40 combines observations and model simulations, is recognized as one effective method
41 to improve air quality forecasts. It has been widely used to assimilate aerosol
42 measurements from both ground-based and space-borne platforms, including surface
43 PM₁₀ observations (Jiang et al., 2013; Pagowski et al., 2014), surface PM_{2.5}
44 observations (Li et al., 2013; Zhang, 2016), Lidar observations (Yumimoto et al., 2007,
45 2008), aerosol optical depth products from AERONET (the AErosol RObotic
46 NETwork) (Schutgens et al., 2010a-b, 2012), and from various satellites (Sekiyama et
47 al., 2010; Liu et al., 2011; Dai et al., 2014). These studies indicate that assimilating
48 observations can substantially improve the spatiotemporal variations of aerosol in the
49 simulation and forecasts.

50 Aerosols are not only primarily emitted, but also with a larger portion secondary
51 formed through reactions with several gaseous-phases precursors and oxidants in the
52 atmosphere (Huang et al., 2014; Nie et al., 2014; Xie et al., 2015). So, observations of
53 trace gases are also useful in assimilating data for aerosol simulations and forecasts.
54 Efforts to assimilate atmospheric-composition observations, like O₃, SO₂, NO, NO₂,
55 CO, and NH₃, have also been made. For example, Elbern et al. (1997, 1999, 2000, 2001,
56 2007) developed a 4D-VAR (four-dimensional variational) system to assimilate surface
57 measurements of O₃, SO₂, NO and NO₂ to improve air quality forecasts with the joint
58 adjustment of initial conditions (ICs) and emission rates. Later, van Loon et al. (2000)
59 assimilated O₃ in the transport chemistry model LOTOS, based on an Ensemble Kalman

60 Filter (EnKF). Heemink and Segers (2002) attempted to reconstruct NO_x and volatile
61 organic compound (VOC) emissions for O₃ forecasting by assimilating O₃. Carmichael
62 et al. (2003, 2008a, 2008b) developed 4D-VAR and EnKF systems to assimilate O₃ and
63 NO₂ to improve ICs and emission sources for O₃ forecasting. Hakami et al. (2005)
64 constrained black carbon (BC) emissions during the Asian Pacific Regional Aerosol
65 Characterization Experiment. Henze et al. (2007, 2009) estimated SO_x, NO_x and NH₃
66 emissions based on a 4D-VAR method by assimilating surface sulfate and nitrate
67 aerosol observations. Other studies have estimated the NO_x (van der et al., 2006, 2017;
68 Mijling et al., 2009, 2012, 2013; Ding. et al., 2015) and SO₂ emissions (van der et al.,
69 2017) based on an extended Kalman filter by assimilating SO₂ and NO₂ retrievals from
70 SCIAMACHY (SCanning Imaging Absorption spectroMeter for Atmospheric
71 CHartography) and OMI (Ozone Monitoring Instrument). Barbu et al. (2009) applied
72 an EnKF to optimize the emissions and conversion rates using surface measurements
73 of SO₂ and sulfate. McLinden (2016) constrained SO₂ emissions using space-based
74 observations.

75 In recent years, severe haze pollution episodes have begun to occur more
76 frequently in China, especially in the megacity clusters of eastern China (e.g., Parrish
77 and Zhu, 2009; Sun et al., 2015; Zhang et al., 2015a). Thus, regional haze, especially
78 when accompanied by extremely high PM_{2.5} concentrations, has drawn significant
79 research interest. However, there are large uncertainties involved in the numerical
80 prediction of atmospheric aerosols. During severe haze pollution episodes, air quality
81 models often underestimate the extreme peak mass concentration of particulate matter
82 (Wang et al., 2014). Previous studies have revealed that the assimilation of atmospheric-
83 composition observations can improve air quality forecasts by constraining the
84 uncertainties of both the chemical ICs and emissions (Tang et al., 2010, 2011, 2013,
85 2016; Miyazaki et al., 2012, 2013, 2014). Peng et al. (2017) demonstrated that
86 significant improvements in forecasting PM_{2.5} can be achieved via the joint adjustment
87 of ICs and source emissions using an EnKF to assimilate surface PM_{2.5} observations.

88 In 2013, China launched an atmospheric environmental monitoring system that
89 provides real-time and online atmospheric chemical observations, including PM₁₀,

90 PM_{2.5}, SO₂, NO₂, O₃, and CO (<http://113.108.142.147:20035/emcpublish/>). This
 91 dataset provides an opportunity to improve air quality forecasts using DA. However,
 92 such fruitful observations are less used in air quality forecast despite of large
 93 discrepancy existed between the forecast and observations. But it is now possible to
 94 estimate the impact on forecast improvement of simultaneously assimilating various
 95 surface observations. Thus, we developed an EnKF system that can simultaneously
 96 assimilate surface measurements of PM₁₀, PM_{2.5}, SO₂, NO₂, O₃ and CO to correct WRF-
 97 Chem (Weather Research and Forecasting model with Chemistry) forecasts using the
 98 Goddard Chemistry Aerosol Radiation and Transport (GOCART) aerosol scheme. As
 99 an extension to Peng et al. (2017), the impact of simultaneously assimilating various
 100 surface aerosol and chemical observations was investigated.

101 Sections 2 and 3 briefly describe the DA system and observations used in this
 102 study, respectively. The experimental design is introduced in Section 4. Finally, the
 103 assimilation results are presented in Section 5, before a brief summary in Section 6.

104

105 **2 DA system**

106 The DA system in this study was the same as the one used in Peng et al. (2017). It
 107 can simultaneously analyze the chemical ICs and emissions with the assimilation of
 108 surface PM_{2.5} observations. A brief summary of the DA system is introduced here.

109 In every DA cycle, the ensemble emission scaling factors λ^f are first calculated
 110 by the forecast model of scaling factors \mathbf{M}_{SF} (see details of \mathbf{M}_{SF} in section 2.2). Then,
 111 the ensemble forecast emissions \mathbf{E}^f are calculated using the following equation:

$$112 \quad \mathbf{E}_{i,t} = \lambda_{i,t} \mathbf{E}_t^p, (i = 1, \dots, N), \quad (1)$$

113 where \mathbf{E}_t^p is the prescribed anthropogenic emission. The ensemble members of
 114 chemical fields \mathbf{C}^f are forecasted using WRF-Chem, forced by the forecast emissions
 115 \mathbf{E}^f whose ICs are previously analyzed concentration fields. Now, the background of
 116 the joint vector, $\mathbf{x}^f = [\mathbf{C}^f, \lambda^f]^T$, has been produced. Then, the analyzed state vector,
 117 $\mathbf{x}^a = [\mathbf{C}^a, \lambda^a]^T$, is optimized using an ensemble square root filter (EnSRF). Finally, the
 118 assimilated emissions \mathbf{E}^a can be obtained using equation (1). It is noted that the

119 optimized emissions are only the results of a mathematical optimum by utilizing
120 observations. If the optimized emissions used in the EnSRF experiment run with pure
121 concentrations as state vectors are identical to the emissions obtained from the joint
122 EnSRF experiment run with concentrations and emission factors (representing
123 emissions) as state vectors, identical results may be obtained.

124

125 **2.1 WRF-Chem model**

126 The model used to simulate the transport of aerosols and chemical species was the
127 WRF-Chem (Grell et al., 2005). As in Peng et al. (2017), we used version 3.6.1 and the
128 physical and chemical parameterization options are listed in Table 1. The model
129 computational domain covered almost the whole China and the horizontal resolution
130 was 40.5 km. Figure 1b shows our area of interest, the North China Plain (NCP). The
131 model included 57 vertical levels and the model top was 10 hPa.

132 The hourly prior anthropogenic emissions were based on the Multi-resolution
133 Emission Inventory for China (MEIC) (Li et al., 2014) for October 2010, instead of the
134 regional emission inventory in Asia (Zhang et al., 2009) for the year 2006 in Peng et al.
135 (2017). The reason we chose the MEIC-2010 was that the total emissions are reasonable
136 for cities over the NCP (Zheng et al., 2016). The original resolution of the MEIC-2010
137 is $0.25^\circ \times 0.25^\circ$, but has been processed to match the model resolution (40.5 km) (Chen
138 et al., 2016). No time variation was added to maintain objectivity in the prior
139 anthropogenic emissions.

140

141 **2.2 Forecast model of scaling factors**

142 In this work, the primary sources to be optimized were the emissions of PM₁₀, PM_{2.5},
143 SO₂, NO, NH₃ and CO. The sources of NH₃ were analyzed because they also impact
144 greatly on the aerosols distribution. Thus, the emission scaling factors $\lambda_{i,t}^f =$
145 $(\lambda_{PM2.5}^f, \lambda_{PM10}^f, \lambda_{SO2}^f, \lambda_{NO}^f, \lambda_{NH3}^f, \lambda_{CO}^f)$ were prepared by the forecast model of scaling
146 operator \mathbf{M}_{SF} before WRF-Chem integration.

147 We used the same persistence forecast operator \mathbf{M}_{SF} to forecast $\lambda_{i,t}^f$ as in Peng

148 et al. (2017). The forecast operator was developed by using the ensemble forecast
 149 chemical fields. Thus,

$$150 \quad \boldsymbol{\kappa}_{i,t} = \frac{\mathbf{C}_{i,t}^f}{\bar{\mathbf{C}}_t^f}, (i = 1, \dots, N), \quad (2)$$

$$151 \quad (\boldsymbol{\kappa}_{i,t})_{\text{inf}} = \beta(\boldsymbol{\kappa}_{i,t} - \bar{\boldsymbol{\kappa}}_t) + \bar{\boldsymbol{\kappa}}_t, (i = 1, \dots, N), \quad (3)$$

$$152 \quad \boldsymbol{\lambda}_{i,t}^p = (\boldsymbol{\kappa}_{i,t})_{\text{inf}}, \quad (4)$$

$$153 \quad \boldsymbol{\lambda}_{i,t}^f = \frac{1}{4}(\boldsymbol{\lambda}_{i,t-3}^a + \boldsymbol{\lambda}_{i,t-2}^a + \boldsymbol{\lambda}_{i,t-1}^a + \boldsymbol{\lambda}_{i,t}^p), (i = 1, \dots, N), \quad (5)$$

154 where $\mathbf{C}_{i,t}^f$ is the i th ensemble member of the chemical fields at time t , and
 155 $\bar{\mathbf{C}}_t^f = \frac{1}{N} \sum_{i=1}^N \mathbf{C}_{i,t}^f$ is the ensemble mean; $\boldsymbol{\kappa}_{i,t}$ is the ensemble concentration ratios and
 156 $\bar{\boldsymbol{\kappa}}_t$ is the ensemble mean of $\boldsymbol{\kappa}_{i,t}$ with values of 1; β is the inflation factor to keep the
 157 ensemble spreads of $\boldsymbol{\kappa}_{i,t}$ at a certain level; $\boldsymbol{\lambda}_{i,t-1}^a$, $\boldsymbol{\lambda}_{i,t-2}^a$ and $\boldsymbol{\lambda}_{i,t-3}^a$ are the previous
 158 assimilated emission scaling factors. It is noted that $\boldsymbol{\lambda}_{i,t}^f$ are spatially varying because
 159 they are calculated by using the spatially varying variables, the forecast chemical fields
 160 $\mathbf{C}_{i,t}^f$. Besides, There are very few negative values for $(\boldsymbol{\kappa}_{i,t})_{\text{inf}}$ after inflation. A quality
 161 control procedure is performed for $(\boldsymbol{\kappa}_{i,t})_{\text{inf}}$ before further appliance. All these
 162 negative data were set as 0 in this work. Then $(\boldsymbol{\kappa}_{i,t})_{\text{inf}}$ were re-centered to ensure the
 163 ensemble mean values of $(\boldsymbol{\kappa}_{i,t})_{\text{inf}}$ were all 1. Besides, another quality control
 164 procedure is performed for $\boldsymbol{\lambda}_{i,t}^a$ to keep them positive. Thus, all $\boldsymbol{\lambda}_{i,t}^f$ and $\boldsymbol{\lambda}_{i,t}^a$ could
 165 be positive.

166 In this study, the ensemble forecast chemical fields of PM₂₅, PM₁₀, SO₂, NO, NH₃
 167 and CO of the previous assimilation cycle are respectively used to calculate the
 168 emission scaling factors ($\boldsymbol{\lambda}_{\text{PM2.5}}^f, \boldsymbol{\lambda}_{\text{PM10}}^f, \boldsymbol{\lambda}_{\text{SO2}}^f, \boldsymbol{\lambda}_{\text{NO}}^f, \boldsymbol{\lambda}_{\text{NH3}}^f, \boldsymbol{\lambda}_{\text{CO}}^f$). Previous works
 169 (Peng et al., 2015, 2017) showed that reasonable results can be obtained when the
 170 ensemble spread of the emission scaling factors ranged from 0.1 to 1. In order to keep
 171 the ensemble spread of the scaling factors at this level in most model area, β is chosen
 172 as 1.3, 1.4, 1.3, 1.2, 1.2, and 1.4 for the ensemble concentration ratios of P₂₅, P₁₀, SO₂,
 173 NO, NH₃ and CO, respectively in Equation (3).

174 Then, the sources $\mathbf{E}_{i,t}^f = (\mathbf{E}_{\text{PM}_{2.5}}^f, \mathbf{E}_{\text{PM}_{10}}^f, \mathbf{E}_{\text{SO}_2}^f, \mathbf{E}_{\text{NO}}^f, \mathbf{E}_{\text{NH}_3}^f, \mathbf{E}_{\text{CO}}^f)$ are calculated
175 using equation (1).

176 From the perspective of PM_{2.5} emissions, these include the unspiciated primary
177 sources of PM_{2.5} $\mathbf{E}_{\text{PM}_{2.5}}^f$, sulfate \mathbf{E}_{SO_4} , and nitrate \mathbf{E}_{NO_3} . We updated $\mathbf{E}_{\text{PM}_{2.5}}^f$, \mathbf{E}_{SO_4}
178 and \mathbf{E}_{NO_3} (including the nuclei and accumulation modes) following Peng et al. (2017).
179

180 **2.3 DA algorithm**

181 The assimilation algorithm employed was the EnSRF proposed by Whitaker and Hamill
182 (2002). The EnKF proposed by Evensen (1994) needs perturbations of observations in
183 practice. Compared to the original EnKF, the EnSRF obviates the need to perturb the
184 observations and avoids additional sampling errors introduced by perturbing
185 observations.

186 We used the same EnSRF as in Schwartz et al. (2012, 2014). The ensemble
187 member was chosen as 50. The localization radius was chosen as 607.5 km, so EnSRF
188 analysis increments were forced to zero at 607.5 km away from an observation (Gaspari
189 and Cohn, 1999). The posterior (after assimilation) multiplicative inflation factor was
190 chosen as 1.2 for all the concentration analysis.

191

192 **2.4 State variables**

193 The DA system provides joint analysis of ICs and emissions following Peng et al.
194 (2017). Among them, 16 WRF-Chem/GOCART aerosol variables are included as the
195 state variables. Besides, chemical species, such as SO₂, NO₂ and O₃ are also included
196 because they are the most important gas-phase precursors or oxidants of the secondary
197 inorganic aerosols. CO is also assimilated because CO is an important tracer of
198 combustion sources, as well as a precursor of O₃ beyond NO₂ (Parrish et al., 1991). The
199 state variables of the emission scaling factors are $\boldsymbol{\lambda} =$
200 $(\boldsymbol{\lambda}_{\text{PM}_{2.5}}, \boldsymbol{\lambda}_{\text{PM}_{10}}, \boldsymbol{\lambda}_{\text{SO}_2}, \boldsymbol{\lambda}_{\text{NO}}, \boldsymbol{\lambda}_{\text{NH}_3}, \boldsymbol{\lambda}_{\text{CO}})$.

201 Similar to weak-coupling DA, the DA system simultaneously updates both the ICs
202 and the emissions, but with no cross-variable update, in order to avoid the effects of

203 spurious multivariate correlations in the background error covariance that may develop
 204 due to the limited ensemble size and errors in both the model and observations
 205 (Miyazaki et al. 2012).

206 For the PM_{2.5} observations, the observation operator is expressed as (Schwartz et
 207 al., 2012)

$$208 \quad y_{\text{pm}25}^f = \rho_d[\mathbf{P}_{25} + 1.375\mathbf{S} + 1.8(\mathbf{OC}_1 + \mathbf{OC}_2) + \mathbf{BC}_1 + \mathbf{BC}_2 \\
 209 \quad + \mathbf{D}_1 + 0.286\mathbf{D}_2 + \mathbf{S}_1 + 0.942\mathbf{S}_2], \quad (6)$$

210 where ρ_d is the dry air density; \mathbf{P}_{25} is the fine unspiciated aerosol contributions; \mathbf{S}
 211 represents sulfate; \mathbf{OC}_1 and \mathbf{OC}_2 are hydrophobic and hydrophilic organic carbon
 212 respectively; \mathbf{BC}_1 and \mathbf{BC}_2 are hydrophobic and hydrophilic black carbon respectively;
 213 \mathbf{D}_1 and \mathbf{D}_2 are dusts with effective radii of 0.5 and 1.4 μm respectively; \mathbf{S}_1 and \mathbf{S}_2 are
 214 sea salts with effective radii of 0.3 and 1.0 μm respectively. In fact, PM_{2.5} observations
 215 were only used to analyze \mathbf{P}_{25} , \mathbf{S} , \mathbf{OC}_1 , \mathbf{OC}_2 , \mathbf{BC}_1 , \mathbf{BC}_2 , \mathbf{D}_1 , \mathbf{D}_2 , \mathbf{S}_1 , \mathbf{S}_2 and $\lambda_{\text{PM}2.5}$. Since
 216 we had no NH_3 observations, PM_{2.5} observations were also used to analyze λ_{NH_3} (see
 217 Table 2). For other control variables, PM_{2.5} observations were not allowed to alter them.

218 For the PM₁₀ observations, the PM₁₀ observation operator is expressed as (Jiang
 219 et al., 2013)

$$220 \quad y_{\text{pm}10}^f = \rho_d[\mathbf{P}_{10} + \mathbf{P}_{25} + 1.375\mathbf{S} + 1.8(\mathbf{OC}_1 + \mathbf{OC}_2) + \mathbf{BC}_1 + \mathbf{BC}_2 \\
 221 \quad + \mathbf{D}_1 + 0.286\mathbf{D}_2 + \mathbf{D}_3 + 0.87\mathbf{D}_4 + \mathbf{S}_1 + 0.942\mathbf{S}_2 + \mathbf{S}_3]. \quad (7)$$

222 Thus,

$$223 \quad y_{\text{pm}10-2.5}^f = \rho_d[\mathbf{P}_{10} + \mathbf{D}_3 + 0.87\mathbf{D}_4 + \mathbf{S}_3], \quad (8)$$

224 meaning that, in the assimilation experiments, we did not use the PM₁₀ observations
 225 directly. In equation (13) and (14), \mathbf{P}_{10} denotes the coarse-mode unspiciated aerosol
 226 contributions; \mathbf{D}_3 and \mathbf{D}_4 are dusts with effective radii of 2.4 and 4.5 μm respectively;
 227 \mathbf{S}_3 is sea salt with effective radii of 3.25 μm . We used the PM_{10-2.5} observations (the
 228 differences between the PM₁₀ observations and the PM_{2.5} observations, $y_{\text{pm}10-2.5}^o =$
 229 $y_{\text{pm}10}^o - y_{\text{pm}25}^o$) to analyze \mathbf{P}_{10} , \mathbf{D}_3 , \mathbf{D}_4 , \mathbf{S}_3 and $\lambda_{\text{PM}10}$. In addition, PM_{10-2.5}
 230 observations were used to analyze \mathbf{D}_5 and \mathbf{S}_4 , since they are coarse-mode mineral dust

231 and sea salt aerosols. $PM_{10-2.5}$ observations were not allowed to impact other control
232 variables.

233 Moreover, as shown in Table 2, SO_2 observations were used to analyze the SO_2
234 concentration and λ_{SO_2} . NO_2 observations were used to estimate the NO , NO_2
235 concentration and λ_{NO} . CO observations were used to analyze the CO concentration
236 and λ_{CO} . And finally, O_3 observations were only used to analyze the O_3 concentration.
237

238 3. Observations and errors

239 The surface chemical observations used in this study were obtained from the Ministry
240 of Ecology and Environment of China. Altogether, there were 876 observational sites
241 over the model domain (Figure 1). At most sites, one measurement was selected
242 randomly for the assimilation experiment on a $0.1^\circ \times 0.1^\circ$ grid. Altogether, 355 stations
243 were kept for the model domain, where 133 assimilation stations were located on the
244 NCP and 40 stations were located in the Beijing–Tianjin–Hebei (BTH) region. Other
245 stations were used for verification purposes: 167 independent stations were located on
246 the NCP and 47 in the BTH region.

247 The observation error covariance matrix \mathbf{R} included measurement errors and
248 representation errors. We assumed that \mathbf{R} is a diagonal matrix (without observation
249 correlation).

250 Following Elbern et al. (2007), the measurement error ε_0 is defined as

$$251 \quad \varepsilon_0 = a + b * \Pi_0, \quad (9)$$

252 where Π_0 represents the measurements for $PM_{2.5}$, $PM_{10-2.5}$, SO_2 , NO_2 , CO or O_3 (units:
253 $\mu g \cdot m^{-3}$). A value of $a = 1.5$ and $b = 0.0075$ was chosen for $PM_{2.5}$, $PM_{10-2.5}$, SO_2 ,
254 and NO_2 . For CO , $a = 10$ and $b = 0.0075$.

255 The representativeness error is defined as

$$256 \quad \varepsilon_r = r\varepsilon_0\sqrt{\Delta x/L}, \quad (10)$$

257 where $r = 0.5$, $\Delta x = 40.5$ km (the model resolution), and $L = 3$ km due to the
258 lack of the information of the station type (Elbern et al., 2007).

259 Finally, the total error (ε_t) is defined as

260
$$\varepsilon_t = \sqrt{\varepsilon_0^2 + \varepsilon_r^2}, \quad (11)$$

261 In order to ensure data reliability, the observations were subjected to quality
262 control before DA. Data values larger than a certain threshold were classified as
263 unrealistic and were not assimilated. The threshold values were chosen as 700, 800,
264 300, 300, 400 and 4000 $\mu\text{g}\cdot\text{m}^{-3}$ for $\text{PM}_{2.5}$, $\text{PM}_{10-2.5}$, SO_2 , NO_2 , O_3 and CO , respectively.
265 In addition, observations leading to innovations exceeding a certain value were also
266 omitted. These threshold values were chosen as 70 $\mu\text{g}\cdot\text{m}^{-3}$ for $\text{PM}_{2.5}$, $\text{PM}_{10-2.5}$, SO_2 ,
267 NO_2 and O_3 . Also, 1500 $\mu\text{g}\cdot\text{m}^{-3}$ was chosen for CO .

268

269 **4. Experimental design**

270 The DA experiment followed that of Peng et al. (2017), in which the assimilation
271 of pure surface $\text{PM}_{2.5}$ measurements with the EnKF was performed to correct finer
272 aerosol variables and associated emissions. The experiment focused on an extreme haze
273 event that occurred in October 2014 over North China.

274 The 50-member ensemble spin-up forecasts were first performed from 1 to 4
275 October 2014 using the perturbed meteorological ICs, lateral boundary conditions
276 (LBCs) and emissions. The perturbed meteorological ICs and LBCs are created by
277 adding Gaussian random noise (Torn et al., 2006) to the temperature, water vapor,
278 velocity, geopotential height and dry surface pressure fields of the products of the
279 National Centers for Environmental Prediction Global Forecast System (GFS) by
280 WRFDA. The perturbed emissions were generated also by adding Gaussian random
281 noise with a standard deviation of 10 percent of the corresponding anthropogenic
282 emissions. The aerosol ICs were zero and the aerosol LBCs were idealized profiles
283 embedded within the WRF-Chem model. And both them are not perturbed (Peng et al.,
284 2017).

285 Then, the observed PM_{10} , $\text{PM}_{2.5}$, SO_2 , NO_2 , O_3 and CO data starting from 5 to 16
286 October were assimilated hourly to adjust the ICs and the corresponding emissions. the
287 ICs were the analysis of the previous DA cycle. The meteorological LBCs were
288 perturbed. The anthropogenic emissions, $\mathbf{E}_{\text{PM}_{2.5}}$, $\mathbf{E}_{\text{PM}_{10}}$, \mathbf{E}_{SO_2} , \mathbf{E}_{NO} , \mathbf{E}_{NH_3} , \mathbf{E}_{CO} ,

289 sulfate E_{SO_4} and nitrate E_{NO_3} are calculated by using the forecast emission scaling
290 factors. Other species, such as the organic compounds E_{org} and elemental compounds
291 E_{BC} , are perturbed by adding Gaussian random noise. Since the emissions are calculated
292 by EQ. (1), their background uncertainties and the spatial correlations are completely
293 dependent on those of the corresponding emission factors. The forecast scaling factors
294 are calculated by EQ. (2) ~ (5). And no other perturbations are added to the scaling
295 factors; no other correlations are assumed for the scaling factors.

296 After that, two sets of 72-h forecasts were performed, each at 00:00 UTC from 6
297 to 15 October 2014, with hourly forecasting outputs for the assimilation experiment.
298 These two sets of forecasting experiments were conducted using the ensemble mean of
299 the concentration analysis as the ICs. One set of the experiments was forced by the
300 optimized emissions (denoted as fcICsEs), and the other was forced by the prescribed
301 anthropogenic emissions (denoted as fcICs). The aim was to use the difference between
302 the fcICsEs and fcICs to indicate the impact of the optimized emissions.

303 Moreover, we also run a control experiment. The ICs were based on the ensemble
304 mean of the spin-up forecasts at 00:00 UTC on 5 October 2014. The emissions were
305 the prescribed emissions.

306

307 **5. Results**

308 5.1 Ensemble performance

309 We begin by assessing the ensemble performance for the DA system. Figure 2 shows
310 the time series of the prior total spreads and the prior root-mean-square errors (RMSEs)
311 for $PM_{2.5}$, PM_{10} , and the four trace gases calculated against all observations in the BTH
312 region. It shows that the magnitudes of the total spreads were close to the RMSEs,
313 indicating that the DA system was well calibrated (Houtekamer et al., 2005).

314 Figure 3 shows the area-averaged time series extracted from the ensemble spread
315 of the six emission scaling factors ($\lambda_{PM_{2.5}}^f$, $\lambda_{PM_{10}}^f$, $\lambda_{SO_2}^f$, λ_{NO}^f , $\lambda_{NH_3}^f$ and λ_{CO}^f) in the
316 BTH region. It shows that the ensemble spread of all the scaling factors were very stable
317 throughout the ~10-day experiment period, which indicates that M_{SF} can generate
318 stable artificial data to generate the ensemble emissions. The value of the emission

319 scaling factors ranged from 0.2 to 0.6, indicating that the uncertainty of the assimilated
320 emissions was about 20%–60%.

321

322 5.2 Forecast improvements

323 In order to evaluate the overall performance of the DA system, time series of the hourly
324 pollutant concentrations from the control run, the analysis, and the first-day forecast of
325 the two forecasting experiments were compared with the independent observations in
326 the BTH region (Figure 4). Besides, model evaluation statistics (Table 3) were
327 calculated against independent observations from 6 to 16 October 2014. In addition,
328 biases and RMSEs were presented as a function of forecast range for the control,
329 analysis, and forecast experiments (Figures 5–7).

330 The control run did not perform very well, although it was able to capture the
331 synoptic variability and reproduce the overall pollutant levels when there was a severe
332 haze event. The statistics show that there were larger systematic biases and RMSEs and
333 a smaller correlation coefficient (CORR) for the control (see Table 3). The biases were
334 -34.1 , -77.7 , -565.7 and $-31 \mu\text{g}\cdot\text{m}^{-3}$ for $\text{PM}_{2.5}$, PM_{10} , CO , and O_3 , respectively, from
335 6 to 16 October—about 29.7%, 44.5%, 42.9% and 53.9% lower than the corresponding
336 observed concentrations. During the severe haze episode from 8 to 10 October in
337 particular, when observed $\text{PM}_{2.5}$ were larger than $200 \mu\text{g}\cdot\text{m}^{-3}$, the biases reached -90.5 ,
338 -143.1 , -911.8 and $-39.1 \mu\text{g}\cdot\text{m}^{-3}$, respectively—about 44.4%, 51.9%, 49.2% and 55.7%
339 lower than the corresponding observed concentrations, suggesting a significant
340 systematic underestimation of the WRF-Chem simulation. Additionally, a significant
341 overestimation of $48.1 \mu\text{g}\cdot\text{m}^{-3}$ was obtained for SO_2 —about 145.8% higher than the
342 observed concentrations. As for the NO_2 simulation, WRF-Chem was able to
343 realistically describe the diurnal and synoptic evolution of NO_2 concentrations. The
344 model bias was $22.4 \mu\text{g}\cdot\text{m}^{-3}$, which was about 39.7% higher than the observed NO_2 .
345 These results were similar to the simulations of Chen et al. (2016). Most of the WRF-
346 Chem settings used here were the same as those used in Chen et al. (2016), except that
347 they used CBMZ (Carbon Bond Mechanism, version Z) and MOSAIC (Model for
348 Simulating Aerosol Interactions and Chemistry) as the gas-phase and aerosol chemical

349 mechanisms.

350 After the assimilation of surface observations, the time series of the hourly
351 pollutant concentrations from the analysis showed much better agreement with
352 observations than those from the control. The magnitudes of the bias and the RMSEs
353 decreased and the CORRs increased for all six species. The biases were 5.1, -5.6, 8.1,
354 -8.3, -160.4 and 2.1 $\mu\text{g}\cdot\text{m}^{-3}$ for PM_{2.5}, PM₁₀, SO₂, NO₂, CO and O₃, respectively—
355 about 4.4%, -3.2%, 24.5%, -14.7%, -12.17% and 3.7% of the corresponding observed
356 concentrations, indicating that the analysis fields were very close to the observations.
357 The RMSEs were 51.5, 63.4, 27.9, 31.7, 618.9 and 31.1 $\mu\text{g}\cdot\text{m}^{-3}$, respectively—about
358 44.1%, 52.9%, 58.1%, 20.2%, 35.7% and 38.78% lower than the RMSEs of the control
359 run. The CORRs reached 0.891, 0.890, 0.540, 0.557, 0.705 and 0.753, respectively.
360 These statistics indicate that the DA system was able to adjust the chemical ICs
361 efficiently.

362 The PM_{2.5}, PM₁₀ and CO concentrations from both sets of forecasting experiments
363 benefitted substantially from the DA procedure, as expected. Smaller biases and
364 RMSEs were obtained for almost the entire 72-h forecast range (see Figures 5–7), as
365 compared with the control run. For the first-day forecast in particular, the model
366 performed almost perfectly. It faultlessly captured the diurnal and synoptic variability
367 of the pollutant (see figure 4), in a manner that was very close to that of the analysis.
368 The overall biases were 6.5, -11.9 and 100.4 $\mu\text{g}\cdot\text{m}^{-3}$ for PM_{2.5}, PM₁₀ and CO,
369 respectively; and the RMSEs were 77.8, 98.7 and 805.1 $\mu\text{g}\cdot\text{m}^{-3}$, respectively, in
370 fcICsEs24 (see Table 3). In fcICs24, the biases were 8.3, -10.3 and 130.2 $\mu\text{g}\cdot\text{m}^{-3}$,
371 respectively; and the RMSEs were 75.1, 95.9 and 838.2 $\mu\text{g}\cdot\text{m}^{-3}$, respectively (see Table
372 3). However, with longer-range forecasts, the impact of DA quickly decayed. The
373 relative reductions in RMSE mostly ranged from 30% to 5% for the second- and third-
374 day forecast. From the perspective of the impact of the assimilated emissions, fcICs
375 performed similarly to fcICsEs for PM_{2.5}, PM₁₀ and CO, indicating that ICs play key
376 roles in aerosol and CO forecasts during severe haze episodes, while the impact of
377 assimilated emissions seems negligible.

378 For the SO₂ verification forecast, however, fcICsEs performed much better than

379 both fcICs and the control run. Smaller biases and RMSEs were obtained for almost the
380 entire 72-h forecast range. At nighttime in particular (from 18 to 23 h, 42 to 47 h, and
381 66 to 73 h), when there was significant systematic overestimation in the control run,
382 both the biases and the RMSEs in fcICsEs were about 30% lower than those of the
383 control run. During the daytime (from 0 to 9 h, 24 to 33 h, and 48 to 57 h), fcICsEs still
384 performed slightly better, although the control run did a near perfect job. As for fcICs,
385 smaller biases and RMSEs were obtained for only the first 3 h. Then, the performance
386 was the same as the control run, indicating that the impact of the ICs had disappeared.
387 These results demonstrate the superiority of the assimilated emissions, and that the joint
388 adjustment of SO₂ ICs and emissions is an efficient way to improve the SO₂ forecast.

389 The NO₂ DA results for the independent sites showed really poor performance
390 (see Figures 5–7). Smaller biases were gained in the daytime of the experiment trials.
391 At nighttime, however, when the simulated NO₂ deviated considerably from the
392 observations in the control run, the biases of both sets of the validation forecasts became
393 even larger. Besides, almost all the RMSEs of both sets of the validation forecasts were
394 always larger than those of the control run.

395 The O₃ DA results were dependent on the NO₂ DA results in the daytime, due to
396 chemical transformation. Both the biases and the RMSEs were larger, as compared with
397 those of the control run (see Figures 5–7). However, at nighttime, when there was
398 significant systematic underestimation in the control run, the biases in fcICsEs had very
399 similar values to those of the analysis. Also, the biases in fcICs ranged between the
400 analysis and the control run; and the RMSEs of both sets of forecasting experiments
401 were about 10% smaller than those of the control run. All these results indicate that the
402 DA system performed well at night.

403

404 5.3 Emission optimization results

405 Besides improved pollutant forecasts, improved estimates of emissions were expected
406 from the joint DA procedure. The MEIC-2010 was constructed on the basis of annual
407 statistical books in which the data were often 2–3 years older than the actual year (Chen
408 et al., 2016). However, consistent efforts aimed at reducing and managing

409 anthropogenic emissions have been made over the past decade to mitigate air pollution.
410 Thus, there was a large difference between the emission year and our simulation year.
411 Besides, the spatial allocations of these emissions over small spatial scales, and the
412 monthly allocations, will also lead to some uncertainties. Lastly, the emissions
413 inventory cannot fully capture the day-to-day variability or the actual daily variations,
414 though its differentiation in terms of working days and weekend days, plus the daily
415 variations, can be taken into account in practical applications. However, in this
416 assimilation procedure, the differentiation in terms of working days and weekend days,
417 plus the daily variations, was ignored. Therefore, the prescribed anthropogenic
418 emissions were subject to large uncertainties.

419 Figures 8 and 9 display the spatial distribution of the prescribed emission rates and
420 the differences between the analysis and the prescribed emission rates of PM_{2.5}, PM₁₀,
421 NH₃, SO₂, NO and CO averaged over all hours from 6 to 16 October 2014 in the NCP
422 region. The assimilated emission rates of PM_{2.5}, SO₂, NO and CO were lower than the
423 prescribed emissions on the whole. In the BTH region especially, the differences
424 reached $-0.02 \mu\text{g}\cdot\text{m}^{-2}\cdot\text{s}^{-1}$, -2.9 , -8.8 and $-24.65 \text{ mol}\cdot\text{km}^{-2}\cdot\text{hr}^{-1}$, which was a reduction
425 of about 10%–20% of the prescribed emissions. For PM₁₀ emissions, the assimilated
426 values were very close to the prescribed ones, indicating that the prescribed PM₁₀
427 emissions had small uncertainties for the NCP region. For NH₃ emissions, the
428 assimilated values were a little larger than the prescribed emissions in large industrial
429 cities like Beijing, Tianjin, Baoding, Xingtai, Handan, and Taiyuan. However, they
430 were smaller than the prescribed emissions in agricultural regions, especially in
431 Shandong Province and Henan Province. However, in the BTH region, the assimilated
432 NH₃ emissions were very close to the prescribed emissions on the whole.

433 Figure 10 shows the time series of the emission scaling factors and the emissions.
434 As concluded in Peng et al. (2017), the forecast emission scaling factors changed with
435 the analyzed emission scaling factors due to the use of the time smoothing operator.
436 Besides, although the prescribed emissions were constant when designing the
437 assimilation experiment, the analyzed emission scaling factors showed obvious
438 variation with time, as did the analyzed emissions. For the assimilated SO₂ and NO

439 emissions in particular, the diurnal variations were perfect. In addition, the difference
440 between the assimilated emissions and the prescribed emissions were consistent with
441 those in Figures 8 and 9. The assimilated emissions of PM_{2.5}, SO₂, NO and CO were
442 apparently lower than the corresponding prescribed emissions. Whereas, the values of
443 the assimilated emissions of PM₁₀ and NH₃ were very close to their corresponding
444 prescribed emissions.

445 In order to investigate the impact of optimized emissions on chemical simulations,
446 a simulation (fcEs) using the optimized emissions were performed from 5 to 16 October
447 2014. Same as the control run, the ICs were the ensemble mean of the spin-up forecasts
448 at 00:00 UTC on 5 October 2014. Thus the difference between the fcEs and the control
449 run is the anthropogenic emissions. The results showed that the fcEs performed very
450 similar to the control run in the whole in the BTH region. For PM_{2.5}, PM₁₀ and CO, the
451 values of the fcEs were a little smaller than those of the control run, which were
452 consistent with the difference of the anthropogenic emissions. For SO₂ and NO₂, fcEs
453 performed much better than the control run in most time though significant systematic
454 overestimation still existed during the nighttime. For O₃, minor improvements were also
455 gained due to the better simulation in fcEs for NO₂.

456

457 5.4 Discussion

458 From the results presented above, it is clear that improvements were achieved for
459 almost all the 72-h verification forecasts using the optimized ICs and emissions for
460 PM_{2.5}, PM₁₀, SO₂ and CO concentrations in the BTH region. However, the 72-h NO₂
461 verification forecasts performed much worse than the control run, due to the
462 assimilation. Plus, the 72-h O₃ verification forecasts performed worse than the control
463 run during the daytime, due to the worse performance of the NO₂ forecasts, although
464 they did perform better at night. However, relatively favorable NO₂ and O₃ forecast
465 results were gained for the Yangtze River delta and Pearl River delta (PRD) regions
466 (see Figure 11). In the PRD region, during the daytime, the three NO₂ forecasts (i.e.,
467 the control run, the fcICsEs, and the fcICs) performed similarly, and had relatively
468 small biases and RMSEs. At nighttime, when there was significant systematic

469 overestimation in the control run, the biases and the RMSEs in fcICsEs were much
470 smaller than those in the control run. For the O₃ 72-h verification forecasts, fcICsEs
471 performed much better than the control run, except for the first 8 h. Also, fcICs
472 improved the O₃ forecasts to some extent from the 9- to 72-h forecast range. These
473 results indicate that DA is still an effective way to improve NO₂ and O₃ forecasts.

474 Regarding the failure to improve the NO₂ and O₃ forecasts in the BTH region,
475 there are three likely factors. And certainly, NO₂ and O₃ forecasts in other areas are also
476 facing similar challenges.

477 Firstly, there are still some limitations for the EnKF method. EnKF assimilation is
478 influenced greatly by model errors and observation errors. There are many sources of
479 uncertainties in air-quality forecast that were not directly considered in this study (such
480 as chemical schemes and parameterizations, meteorology, and emissions). And it is
481 very difficult to accurately evaluate the uncertainties of models, though the covariance
482 inflation technique was simply applied for all state variables to roughly compensate for
483 model errors. Therefore, we can only obtain suboptimal results through EnKF
484 assimilation. Furthermore, for short-lived chemical reactive species, such as NO₂ and
485 O₃, they undergo highly complex nonlinear photochemical reactions, even
486 on timescales of hours, such that the forecast accuracy is largely dependent on the
487 chemical process as well as the physical transportation process, the ICs, and the
488 emissions. However, those complex photochemical reaction processes are not precisely
489 described in current chemical mechanisms, e.g., heterogeneous reactions (Yang et al.,
490 2015), the photolysis of nitrous acid and ClNO₂ during daytime (Zhang et al., 2017),
491 and so on. Therefore, on the one hand, there are still large uncertainties for NO₂ and O₃
492 forecasts; whilst on the other hand, it is very difficult for NO₂ and O₃ DA to accurately
493 estimate the model errors with a limited ensemble size. Thus, NO₂ and O₃ assimilations
494 do not perform well (Elbern et al., 2007; Tang et al., 2016). However, for SO₂ and CO,
495 which are representative of long-lived chemical reactive species, the chemical reaction
496 process does not work on timescales of hours, meaning that to some extent hourly
497 chemical DA has the potential to improve their forecasts. For CO in particular, due to
498 its inertness, we might be able to obtain high-quality ICs and emissions through DA.

499 The primary sources of aerosol are the dominant part of the atmospheric aerosol
500 concentration. So, 72-h aerosol forecasts may perform similarly to CO, albeit there are
501 large uncertainties in the chemical model.

502 Secondly, as stated in the above paragraph, the analysis ICs and emissions are only
503 a mathematical optimum under the existing conditions. In addition, only part of the
504 chemical ICs and emissions are involved in the DA experiment; and VOC ICs and
505 emissions, which may greatly influence the NO₂ and O₃ forecasts, were not included
506 here because of the absence of VOC measurements. Although we carried out two DA
507 sensitivity experiments to adjust the VOC ICs and emissions through the use of NO₂ or
508 O₃ measurements, we were still unable to gain improved NO₂ and O₃ forecasts in the
509 BTH region in both DA experiments. VOC measurements are needed to reduce
510 uncertainties of VOC ICs and emissions. In addition, almost all available data were
511 observed in cities, and no observation stations located in rural. Thus, the
512 atmospheric environmental monitoring system was still spatially heterogeneous.

513 Another important point is that there are still limitations to the current chemical
514 mechanisms used in our model, such as the treatment of model error. NO is the primary
515 species of NO_x emissions in city areas, and reacts directly with O₃ to form NO₂ (NO+O₃
516 →NO₂+O₂). Thus, O₃ concentrations may inversely correlate with NO₂ concentrations
517 at night. Consequently, air quality models may systematically underestimate O₃
518 concentrations. Currently, DA can only revise the ICs and the emissions in this work. It
519 cannot change the model performance, especially when there are certain uncertainties
520 for the meteorological simulation.

521

522 **6. Summary**

523 In this study, we developed an EnKF system to simultaneously assimilate surface
524 measurements of PM₁₀, PM_{2.5}, SO₂, NO₂, O₃ and CO via the joint adjustment of ICs
525 and source emissions. This system was applied to assimilate hourly pollution data while
526 modeling an extreme haze event that occurred in early October 2014 over North China.
527 In order to evaluate the impact of DA, two sets of 72-h verification forecasts were
528 performed. One was conducted with the optimized ICs and emissions, and the other

529 with only optimized ICs and the prescribed emissions. A control experiment without
530 DA was also performed for comparison.

531 The results showed that both verification forecasts performed much better than the
532 control simulations for PM_{2.5}, PM₁₀ and CO. Obvious improvements were achieved for
533 almost the entire 72-h forecast range. For the first-day forecast especially, near perfect
534 forecasts results were achieved. However, with longer-range forecasts, the impact of
535 DA quickly decayed. In addition, the forecasts with only optimized ICs and the
536 prescribed emissions performed similarly to that with the optimized ICs and emissions,
537 indicating that ICs play key roles in PM_{2.5}, PM₁₀ and CO forecasts during severe haze
538 episodes.

539 Also, large improvements were achieved for SO₂ forecasts with both the optimized
540 ICs and emissions for the whole 72-h forecast range. However, similar improvements
541 were achieved for SO₂ forecasts with the optimized ICs only for just the first 3 h, and
542 then the impact of the ICs decayed quickly to zero. This demonstrates that the joint
543 adjustment of SO₂ ICs and emissions is an efficient way to improve SO₂ forecasts.

544 Even though we failed to improve the NO₂ and O₃ forecasts in the BTH region,
545 relatively favorable NO₂ and O₃ forecast results were gained in other areas. Also, the
546 forecasts with both the optimized ICs and emissions performed much better than the
547 forecasts with only optimized ICs and the prescribed emissions. These results indicate
548 that there is still potential to improve NO₂ and O₃ forecasts via the joint adjustment of
549 SO₂ ICs and emissions.

550 However, only a case was investigated in this work. Thus it is uncertain if the
551 conclusions about different performance of forecasts for various species would hold in
552 a general. Therefore, more case studies are needed to obtain general conclusions in
553 future works.

554

555 **Data availability.** To reproduce the data presented in the draft, the WRF-Chem model
556 version 3.6.1 can be downloaded at
557 http://www2.mmm.ucar.edu/wrf/users/download/get_source.html; the meteorological
558 background is provided by GFS data (0.5°) which can be downloaded from

559 <https://www.ncdc.noaa.gov/data-access/model-data/model-datasets/global-forecast->
560 [system-gfs;](https://www.ncdc.noaa.gov/data-access/model-data/model-datasets/global-forecast-system-gfs/) the observations are available from
561 <http://113.108.142.147:20035/emcpublish/>.

562 **Competing interests.** The authors declare that they have no conflict of interest.

563 **Acknowledgements.** The authors are grateful to the two anonymous reviewers for their
564 precious suggestions. This work was supported by the National Key Technologies
565 Research and Development program of China (2016YFC0202102), and the National
566 Natural Science Foundation of China (41875014, 41575141 and 41675052). The
567 National Center for Atmospheric Research is sponsored by US National Science
568 Foundation. The numerical calculations in this paper were carried out on the IBM Blade
569 cluster system in the High Performance Computing Center (HPCC) of Nanjing
570 University.

571 **Author contributions.** Zhen Peng and Zhiqian Liu planned the research and
572 developed the algorithm. Zhen Peng, Jianning Sun and Aijun Ding designed the
573 experiments. Zhen Peng, Lili Lei and Junmei Ban developed the model code. Zhen
574 Peng and Kekuan Chu performed the simulations and analysis. Dan Chen provided the
575 anthropogenic emissions for the model. Xingxia Kou performed the quality control
576 procedure for the observations. Zhen Peng prepared the manuscript with contributions
577 from all co-authors.

805 Table 2. State vectors in the data assimilation system.

806 Figure 1. The model domain (left) and the North China Plain (right). Black dots are the
807 observational sites used for assimilation, and red stars are the observational sites used
808 for validation. The green frame marks the Beijing–Tianjin–Hebei region.

809 Figure 2. Time series of prior ensemble mean RMSE (blue line) and total spread (black
810 line) for PM_{2.5}, PM₁₀, SO₂, NO₂, CO and O₃ concentrations aggregated over all
811 observations over the Beijing–Tianjin–Hebei region. Units for all these variables are
812 $\mu\text{g}\cdot\text{m}^{-3}$.

813 Figure 3. Time series of the area-averaged ensemble spread for the emission scaling
814 factors over the Beijing–Tianjin–Hebei region.

815 Figure 4. Time series of the hourly pollutant concentrations in the Beijing–Tianjin–
816 Hebei (BTH) region obtained from observations (red line), the control run (black line),
817 the analysis (pink line), the first-day forecast from fcICsEs (fcICsEs24, blue line), and
818 the first-day forecast from fcICs (fcICs24, blue line). The observations were obtained
819 from the 47 independent sites in the BTH region. The modelled time series were
820 interpolated to the 47 independent sites using the spatial bilinear interpolator method.
821 The shaded backgrounds indicate the distribution of the observations, where the top
822 edge represented the 90th percentile and the bottom edge the 10th percentile. Units:
823 $\mu\text{g}\cdot\text{m}^{-3}$.

824 Table 3. Comparison with observations of the surface PM_{2.5} mass concentrations in the
825 Beijing–Tianjin–Hebei region from the control experiment, the assimilation experiment,
826 and the first-day forecast, over all analysis times from 6 to 16 October 2014. Units:
827 $\mu\text{g}\cdot\text{m}^{-3}$.

828 Figure 5. Bias of surface PM_{2.5}, PM₁₀, SO₂, NO₂, CO and O₃ as a function of forecast
829 range calculated against all the independent observations over the Beijing–Tianjin–
830 Hebei region shown in Figure 1. The 72-h forecasts were performed at each 0000 UTC
831 from 6 to 14 October 2014 and the statistics were computed from 6 to 14 October. Units:
832 $\mu\text{g}\cdot\text{m}^{-3}$.

833 Figure 6. As in Figure 5 but for RMSE. Units: $\mu\text{g}\cdot\text{m}^{-3}$.

834 Figure 7. Normalized RMSE (assimilation divided by control) for fcICsEs and fcICs
835 for PM_{2.5}, PM₁₀, SO₂ and CO.

836 Figure 8. Spatial distribution of the prescribed emissions (top panels) of PM_{2.5} (left), PM₁₀ (middle),
837 and NH₃ (right) and the corresponding time-averaged differences between the ensemble mean
838 analysis and the prescribed values at the lowest model level averaged over all hours from 6 to
839 16 October 2014 in the NCP region. Units for PM_{2.5} and PM₁₀ emissions: $\mu\text{g}\cdot\text{m}^{-2}\cdot\text{s}^{-1}$; and
840 for NH₃ emissions: $\text{mol}\cdot\text{km}^{-2}\cdot\text{hr}^{-1}$.

841 Figure 9. As in Figure 8 but for SO₂ (left), NO (middle), and CO (right). Units for SO₂, NO
842 and CO emissions: $\text{mol}\cdot\text{km}^{-2}\cdot\text{hr}^{-1}$.

843 Figure 10. Hourly area-averaged time series extracted from the analyzed emission
844 scaling factors (black line), the forecast emission scaling factors (green dashed line),
845 the analyzed emissions (blue line), and the prescribed emissions (blue dashed line) in
846 the Beijing–Tianjin–Hebei region. Units for PM_{2.5} and PM₁₀ emissions: $\mu\text{g}\cdot\text{m}^{-2}\cdot\text{s}^{-1}$; and
847 for NH₃, SO₂, NO and CO emissions: $\text{mol}\cdot\text{km}^{-2}\cdot\text{hr}^{-1}$.
