17

18 **Abstract:** Heavy haze usually occurs in winter in eastern China. To control the severe air pollution during the season,
19 comprehensive regional joint-control strategies were implemented throughout a campaign. To evaluate the
20 effectiveness of these strategies and to provide some insights into strengthening the regional joint-control
21 mechanism, the influence of control measures on levels of air pollution were estimated with an integrated
22 measurement-emission-modeling method. To determine the influence of meteorological conditions, and the control
23 measures on the air quality, in a comprehensive study, the 2nd World Internet Conference was held during December
24 16~18, 2015 in Jiaxing City, Zhejiang Province in the Yangtze River Delta (YRD) region. We first analyzed the air
25 quality changes during four meteorological regimes; and then compared the air pollutant concentrations before,
26 during and after the regulation under static meteorological conditions. Next, we conducted modeling scenarios to
27 quantify the effects caused due to the air pollution control measures. We found that total emissions of SO₂, NO_x,
28 PM_{2.5} and VOCs in Jiaxing were reduced by 56%, 58%, 64% and 80%, respectively; while total emission reductions
29 of SO₂, NO_x, PM_{2.5} and VOCs over the YRD region are estimated to be 10%, 9%, 10% and 11%, respectively.
30 Modelling results suggest that during the campaign from December 8 to December 18, PM_{2.5} daily average
31 concentrations decreased by 10 µg/m³ with an average decrease of 14.6%. Our implemented optimization analysis
32 compared with previous studies also reveal that local emission reductions play a key role in air quality improvement,
33 although it shall be supplemented by regional linkage. In terms of regional joint control, to implement pollution
34 channel control 48 hours before the event is of most benefit in getting similar results. Therefore, it is recommended
35 that a synergistic emission reduction plan between adjacent areas with local pollution emission reductions as the
36 core part should be established and strengthened, and emission reduction plans for different types of pollution
37 through a stronger regional linkage should be reserved.

39

40 **1 Introduction**

41 High concentrations of PM_{2.5} has attracted much attention due to its impact on visibility (Pui et al., 2014),
42 human health (West et al., 2016) and global environment. To control air pollution situation in China, the Ministry
43 of Ecology and Environment of the People's Republic of China has released a lot of policies, which can generally
44 be divided into long-term action plans (such as the Clean Air Action Plan (2013-2017), the Five-year Action Plans)
45 and short-term control measures (such as Clean Air Protection during Mega Events, Air Pollution Warning and
46 Protection Measures). China has successfully implemented some mega event air pollution control plans and ensured
47 good air quality, including the 2008 Beijing Olympics (Kelly and Zhu, 2016); the 2010 World Expo in Shanghai
48 (CAI-Asia, 2010); the 2010 Guangzhou Asian Games (Liu et al., 2013); the 2014 Asia-Pacific Economic
49 Cooperation Forum (APEC) (Liang et al., 2017); 2014 Summer Youth Olympics in Nanjing (CAI-Asia, 2014) and
50 the 2015 China Victory Day Parade (Victory Parade 2015) (Liang et al., 2017), etc. After implementation of these
51 control measures, it is important to understand how effective these strategies are.

52 The 2nd World Internet Conference was held in Tongxiang, Jiaxing, Zhejiang during 16-18 December, 2015.
53 To reduce air pollution during the conference, Zhejiang Province and the Regional Air-pollution Joint Control
54 Office of the Yangtze River Delta (YRD) region developed an Action Plan for Air Pollution Control during the
55 Conference (henceforth referred to as the Action Plan), which clarified target goals, time periods for implementing
56 controls, regions in which the controls would be applied, and the control measures to be implemented, as described
57 below. **Targets:** achieve an Air Quality Index (AQI) below 100 in “key areas”, an AQI below 150 in “control areas”,
58 and to achieve significant improvement of the air quality in the surrounding (or buffer) regions outside the control
59 areas. **Time Periods:** the time periods of interest for implementing various controls include the early stage (3 months
60 before the conference), the advanced stage (2 weeks to 4 days before the conference) and the central stage (3 days
61 before and 2 days after the conference). **Regions:** areas within a 50km radius, within a 100km radius and outside of
62 a 100km radius from the centre of Tongxiang were classified as key areas, control areas and buffer areas,
63 respectively. These areas cover 9 cities including Jiaxing, Huzhou, Hangzhou, Ningbo and Shaoxing in Zhejiang
64 province, Suzhou and Wuxi in Jiangsu province and Xuancheng in Anhui province, as shown in Fig.1.

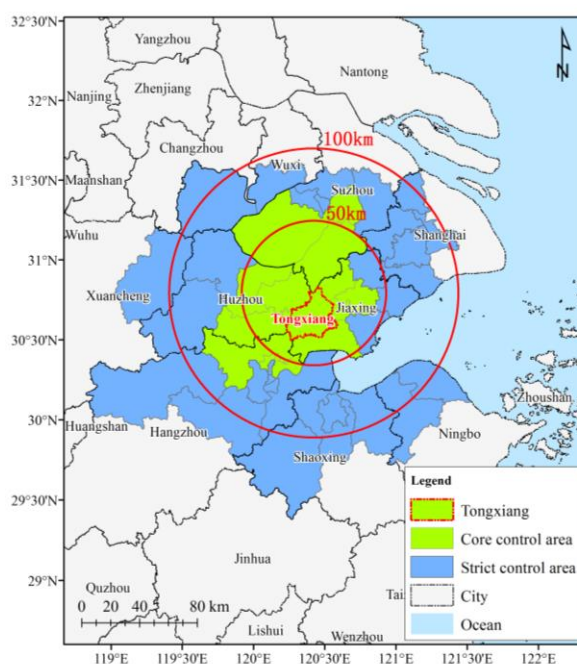

Fig.1 Controlled regions in the Action Plan for Air Quality Control during the World Internet Conference

Many studies have provided descriptive analysis of changing concentrations of air pollutants during mega events; some have reported the emission reductions and related air quality changes (Wang, et al., 2009; Wang, et al., 2010; Liu, et al., 2013; Tang, et al., 2015; Li, et al., 2016; Wang, et al., 2016; Sun, et al., 2016; Wang, et al., 2015; Chen, et al., 2017; Han, et al., 2016; Qi, et al., 2016). However, different air pollution control targets, different control measures, and different locations, may cause significantly different effects among those strategies. In this paper, the reduction in $PM_{2.5}$ achieved through the Action Plan is investigated further to help quantify the level of $PM_{2.5}$ reduction that can be attributed to different aspects of the Action Plan. An integrated emission-measurement-modelling method described in the next section including analysis of multi-pollutant observations, backward trajectory and potential source contribution analyses, estimates of pollutant emission reductions, and photochemical model simulations were adopted to conduct a comprehensive assessment of the impact of control measures on air quality improvement based on three aspects: meteorological conditions, pollutant emission reductions of local sources, and regional contributions.

2 Methodology

In order to strengthen the regional air pollution joint-control mechanism in the YRD region, various measures and their implementation were systematically reviewed, and the qualitative and quantitative relationships among the implementation of measures, changes in emissions of air pollution sources and air quality improvement were studied. Specifically, the impact of measures such as management and control of coal-burning power plants, production restriction and suspension of industrial enterprises, motor vehicle limitation and work site suspension,

85 dust control were investigated. In addition, the role of meteorology (in particular, transport) was assessed in terms
86 of its influence on the relevance and effectiveness of various measures, and ways of optimising air quality control
87 measures and emergency emission reductions under heavy pollution during major events were evaluated.

88 To assess the effectiveness of the various controls outlined in the Action Plan, emission reductions associated
89 with those controls were calculated, and photochemical modelling was conducted to determine the change in $PM_{2.5}$
90 attributed to specific controls. On this basis, an assessment of how to optimise control measures was carried out
91 with respect to both the area in which the emission reduction took place, as well as the start time for implementing
92 the controls (i.e., how far in advance do the controls need to be implemented). Analysis of the numerical modelling
93 results is focused on the effectiveness of the control measures with respect to regional transport of pollutants in the
94 YRD region.

95 **2.1 Measurements**

96 The On-line observational station was set up at the Shanxi supersite of Zhejiang Province ($30.82^{\circ}N$, 120.87
97 $^{\circ}E$), which was located at the core area for pollution-control measures. On-line hourly $PM_{2.5}$ mass concentration,
98 carbonaceous aerosols, elements, and ionic species were measured by the Synchronized Hybrid Ambient Real-time
99 Particulate Monitor (SHARP, model 5030, Thermo Fisher Scientific Corporation, USA), the OC/EC carbon aerosol
100 analyzer (Model-4, Sunset Laboratory Corporation, USA), the Xact multi-metals monitor (XactTM 625, PALL
101 Corporation, USA), and the Ambient Ion Monitor-Ion Chromatograph (AIM IC, model URG 9000, URG
102 Corporation, USA), respectively. Meteorological parameters, including wind speed, wind direction, temperature,
103 pressure, and relative humidity, were measured as well.

104 $PM_{2.5}$ concentration data quality conform to the standards of data quality control published by Ministry of
105 Ecology and Environment of the People's Republic of China.

106 A semi-continuous Sunset OC/EC analyser was used to measure OC and EC mass loadings at the observation
107 site by adopting NIOSH-5040 protocol based on thermal-optical transmittance (TOT). The ambient air was first
108 sampled into a $PM_{2.5}$ cyclone inlet with a flow rate of $8\text{ L}\cdot\text{min}^{-1}$. The OC and EC were collected on a quartz fiber
109 filter with an effective collection area of 1.13 cm^2 . The analyzer was programmed to collect aerosol for 45 min at
110 the start of each hour, followed by the analysis of carbonaceous species during the remainder of the hour. The
111 analysis procedure is described in detail by Huang et al. (2018)

112 The ionic concentrations of nitrate, sulphate, chloride, sodium, ammonium, potassium, calcium and
113 magnesium (Na^+ , K^+ , Ca^{2+} , NH_4^+ , Mg^{2+} , NO_3^- , SO_4^{2-} , Cl^-) in the fine fraction ($PM_{2.5}$) were measured with a 1-hour
114 time resolution using the AIM IC. The sample analysis unit is composed by an anion and a cation ion

115 chromatographs (Dionex ICS-1100), which was using guard columns with potassium hydroxide eluent (KOH) for
116 the anion system and methane sulfonic acid (MSA) eluent for the cation system. The limit of the detection reported
117 by the manufacturer is 0.1 ug/m³ for all species. The operation principle of AIM-IC is described in detail by
118 Markovic et al. (2012)

119 Hourly ambient mass concentrations of sixteen elements (K, Ca, V, Mn, Fe, As, Se, Cd, Au, Pb, Cr, Ni, Cu,
120 Zn, Ag, Ba) in PM_{2.5} were determined by the Xact multi-metals monitor. In brief, the Xact instrument samples the
121 air through a section of filter tape at a flow rate of 16.7 lpm using a PM_{2.5} sharp cut cyclone. The exposed filter tape
122 spot then advances into an analysis area where the collected PM_{2.5} is analyzed by energy-dispersive X-ray
123 fluorescence (XRF) to determine metal mass concentrations. The sequence of sampling and analysis were performed
124 continuously and simultaneously on an hourly basis.

125 2.2 Potential Source Contribution Analysis

126 TrajStat is a HYSPLIT model developed by Chinese Academy of Meteorological Sciences and NOAA Air
127 Resources Laboratory based on geographic information system (GIS). It uses statistical methods to analyze air mass
128 back trajectories to cluster trajectories and compute potential source contribution function (PSCF) with observation
129 data and meteorological data included (Wang et al., 2009).

130 PSCF analysis is a conditional probability function using air mass trajectories to locate pollution sources. It
131 can be calculated for each 1° longitude by 1° latitude cell by dividing the number of trajectory endpoints that
132 correspond to samples with factor scores or pollutant concentrations greater than specified values by the number of
133 total endpoints in the cell (Zeng et al., 1989). Therefore, pollution source areas are indicated by high PSCF values.
134 Since the deviation of PSCF results could increase with the raise of distance between cell and receptor, therefore a
135 weight factor (W_{ij}) was adopted in this study to lower the uncertainty of PSCF results. PSCF and W_{ij} calculations
136 are described in Eq. (1) and Eq. (2), where m_{ij} is the number of trajectory endpoints greater than specified values in
137 cell (i, j), n_{ij} is the number of total endpoints in this cell (Zeng et al., 1989; Polissar et al., 1999).

$$138 \quad P = \frac{m_{ij}}{n_{ij}} \cdot W(n_{ij}) \quad (1)$$

$$139 \quad W(n_{ij}) = \begin{cases} 1.00, & 80 < n_{ij} \\ 0.70, & 20 < n_{ij} \leq 80 \\ 0.42, & 10 < n_{ij} \leq 20 \\ 0.05, & n_{ij} \leq 10 \end{cases} \quad (2)$$

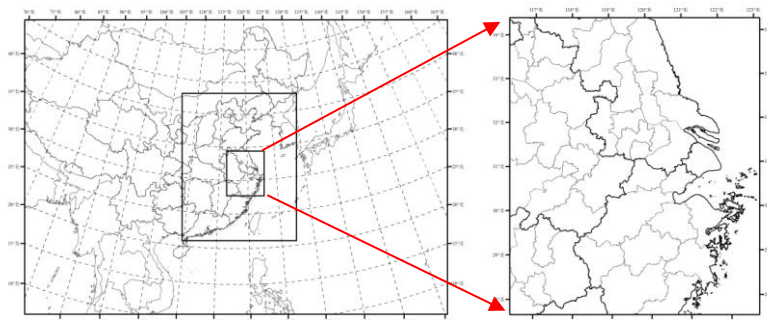

140 In this study, the TrajStat modelling system was used to analyze potential source contribution areas of PM_{2.5}
141 in Jiaying during different pollution episodes with the combination of Global Data Assimilation System (GDAS)
142 meteorological data provided by the NCEP (National Center for Environmental Prediction). Polluted air mass

143 trajectories corresponded to those trajectories with PM_{2.5} hourly concentration higher than 75 µg/m³.

144 2.3 Model setup

145 2.3.1 Model selection and parameter settings

146 In this study, the WRF-CMAQ/CAMx air quality numerical modelling system was used to evaluate the
147 improvement in air quality resulting from the control measures outlined in the Action Plan. It takes into account of
148 modeling variations from different air quality models. For the mesoscale meteorological field, we adopted the WRF
149 model Version 3.4 (<https://www.mmm.ucar.edu/wrf-model-general>), the CAMx model Version 6.1
150 (<http://www.camx.com/>) and the CMAQ model Version 5.0 (Nolte et al., 2015; <http://www.cmascenter.org/cmaq/>).
151 The chemical mechanism utilized in CMAQ was the CB05 gas phase chemical mechanism (Yarwood, et al., 2005)
152 and AERO5 aerosol mechanism, which includes the inorganic aerosol thermodynamic model ISORROPIA (Nenes,
153 et al., 1998) and updated SOA yield parameterizations. The gaseous and aerosol modules used in CAMx are the
154 CB05 chemical mechanism and CF module, respectively. The aqueous-phase chemistry for both models is based
155 on the updated mechanism of the Regional Acid Deposition Model (RADM) (Chang et al., 1987). Particulate Source
156 Apportionment Technology (PSAT) coupled in the CAMx is applied to quantify the regional contributions to PM_{2.5}
157 as well. The WRF meteorological modeling domain consists of three nested Lambert projection grids of 36km-
158 12km-4km, with 3 grids larger than the CMAQ/CAMx modeling domain at each boundary. WRF was run
159 simultaneously for the three nested domains with two-way feedback between the parent and the nest grids. Both the
160 three domains utilized 27 vertical sigma layers with the top layer at 100hpa, and the major physics options for each
161 domain listed in Table 1. For the CMAQ/CAMx modelling domain shown in Figure 2, we adopted a 36-12-4km
162 nested domain structure with 14 vertical layers, which were derived from the WRF 27 layers. The two outer domains
163 cover much of eastern Asia and eastern China, respectively, while the innermost domain covers the YRD region.
164 The simulation period was from 1-18 December, 2015, during which 1-7 December was utilized for model spin-up
165 and 8-18 December was the key period for analysis of the modelling results with control measures.

166
167 Fig 2. Modeling domain
168

Table 1 Parameterization scheme of the physical processes in the WRF model

Physical Processes	Parameterization Scheme	Reference
Microphysical Process	Purdue Lin Scheme	(Lin, 1983)
Cumulus Convective Scheme	Grell-3 Scheme	(Grell and Dévényi, 2002)
Road Process Scheme	Noah Scheme	(Ek, 2003)
Boundary Layer Scheme	Yonsei University (YSU) Scheme	(Hong, 2006)
Long-wave Radiation	RRTM Long-wave Radiation Scheme	(Mlawer et al., 1997)
Short-wave Radiation Scheme	Goddard Short-wave Radiation Scheme	(Chou and Suarez, 1999)

170 Initial and boundary conditions (IC/BCs) for the WRF modeling were based on 1-degree by 1-degree grids
 171 FNL Operational Global Analysis data that are archived at the Global Data Assimilation System (GDAS). Boundary
 172 conditions to WRF were updated at 6-hour intervals for D01.

173 Anthropogenic source emission inventory in YRD is based on a most recent inventory developed by our group
 174 (Huang et al., 2011; Li et al., 2011; Liu et al., 2018). The emission inventory for areas outside YRD in China is
 175 derived from the MEIC model (Multi-resolution Emission Inventory of China, latest data for
 176 2012(<http://www.meicmodel.org>) and anthropogenic emissions over other Asian region are from the MIX emission
 177 inventory for 2010 (Li et al., 2017). Biogenic emissions are calculated by the MEGAN v2.1 (Guenther et al., 2012).
 178 We further developed a controlled emission inventory to account for the control measures based on the emission
 179 reduction requirements described in the control measures plan and the control measures for the emergency air
 180 pollution warning. These estimates are basically according to the control measures and reduction requirements for
 181 specific source sectors and cities described the control plan. The Sparse Matrix Operator Kernel Emissions (SMOKE,
 182 <https://www.cmascenter.org/smoke>) model is applied to process these emissions for modeling inputs that is more
 183 detailed emission processes and not usually used in China.

184 2.3.2 Model performance

185 Prior to evaluating the effectiveness of the control measures and reactions, the performance of the modelling
 186 system was evaluated to ensure it was able to reasonably reproduce the observed meteorological conditions and
 187 PM_{2.5} levels. Statistical indexes used for model evaluation include Normalised Mean Bias (NMB), Normalised
 188 Mean Error (NME) and Index of Agreement (IOA). The equations to calculate these statistical indexes are as follows:

$$189 \quad NMB = \frac{\sum(P_j - O_j)}{\sum O_j} \times 100\% \quad (3)$$

$$190 \quad NME = \frac{\sum |P_j - O_j|}{\sum O_j} \times 100\% \quad (4)$$

$$IOA = 1 - \frac{\sum(P_j - O_j)^2}{\sum(|P_j - \bar{O}| + |O_j - \bar{O}|)^2} \quad (5)$$

189 where P_j and O_j are predicted and observed hourly concentrations, respectively. \bar{O} is the average value of
 190 observations. IOA ranges from 0 to 1, with 1 indicating perfect agreement between model and observation.

191 Observational data from the Shanxi supersite in Jiaxing City were compared with model results for model
 192 evaluation verification. Table 2 shows the summary statistics for the main meteorological parameters simulated
 193 with the WRF model and hourly PM_{2.5} concentrations simulated by CMAQ. Among the meteorological parameters,
 194 wind speed is slightly over predicted with the NMB value of 28%, while temperature, relative humidity and pressure
 195 all have IOA values greater than 0.9. Figure 3 compares the simulated and observed PM_{2.5} concentrations at the
 196 Shanxi supersite. In general, model predicted data are lower than the observed data with the NMB value of -22% to
 197 -30%, the NME value of 45% to 47% and the IOA value of 0.67 to 0.70 (Table 2). These underestimations may be
 198 due to three reasons: Firstly, winter underestimation of PM_{2.5} (especially SOA) is a common issue with CMAQ or
 199 CAMx simulations over China (Hu et al., 2017; Li et al., 2016), which can be explained by a lack of model calculated
 200 oxidants or missing reactions (Kasibhatla et al., 1997) of SOA formation pathways (Appel et al., 2008; Foley et al.,
 201 2010). Secondly, uncertainty still exists in the regional emission inventory, including the basic emissions inventory
 202 and the control scenarios. Thirdly, the wind speed is slightly overestimated over the region, with NMB and NME
 203 of 28% and 33%, causing fast dispersion of air pollutants. Overall, these statistics for both the meteorological
 204 parameters and simulated PM_{2.5} are generally consistent with the results in other published modelling studies(Zheng
 205 et al., 2015;Wang et al., 2014;Zhang et al., 2011;Fu et al., 2016;Li et al., 2015b;Li et al., 2015a), which suggests
 206 that the simulation performance is acceptable.

207 Table 2 Statistics of simulation verification for meteorological parameters and hourly PM_{2.5} concentration

Statistical indexes	Wind speed	Temperature	Relative humidity	Air pressure	CAMx-PM _{2.5}	CMAQ-PM _{2.5}
NMB	28%	3%	-9%	0%	-30%	-22%
NME	33%	14%	12%	0%	45%	47%
IOA	0.81	0.97	0.93	1.00	0.67	0.70

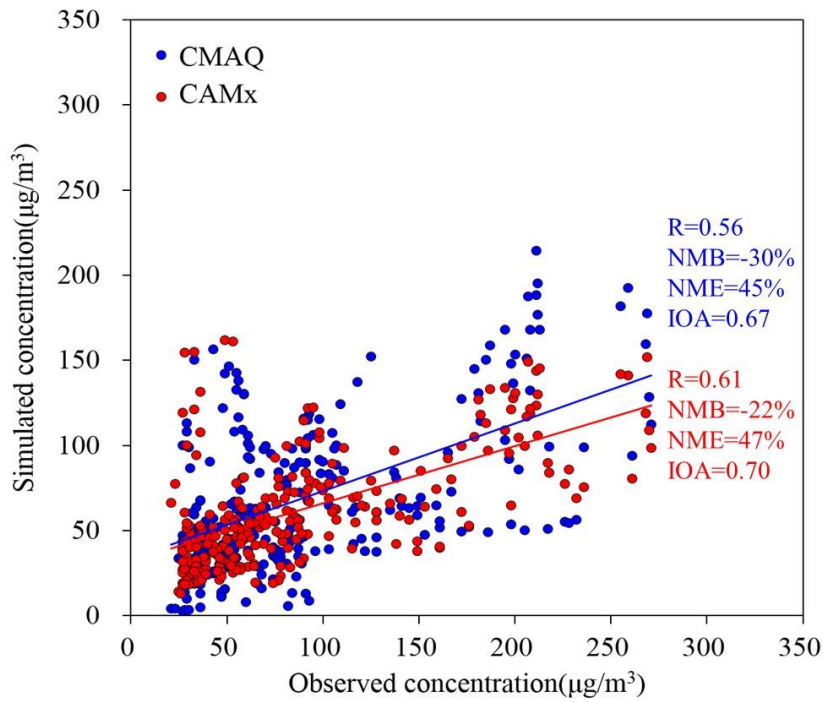

Fig. 3 Scatter plot of the simulated and observed PM_{2.5} at the Shanxi supersite

2.3.3 Method for quantifying the effectiveness of a control

Quantifying the PM_{2.5} reduction in response to emission reductions was done using the so called Brute Force Method (BFM) (Burr and Zhang, 2011), where a baseline scenario was simulated using unadjusted emissions (i.e., those emissions that would have occurred in absence of the Action Plan) and a campaign scenario was modelled based on the emission controls outlined in the Action Plan. In both cases, the same meteorology and chemical boundary conditions were utilized to drive the photochemical model simulations. Through a comparative analysis of the scenarios, a relative improvement factor (RF) for a given atmospheric pollutant, resulting from emission controls, can be calculated and combined with ground based observations to assess the improvement in air quality associated with those emission controls.

$$RF = (C_b - C_s) / C_b \quad (6)$$

$$C_d = C_o \cdot RF \quad (7)$$

where C_b is the simulated pollutant concentration in the baseline scenario ($\mu\text{g}/\text{m}^3$), C_s is the pollutant concentration in the campaign scenario ($\mu\text{g}/\text{m}^3$), C_o denotes the actual observed concentration at the site ($\mu\text{g}/\text{m}^3$) and C_d is the concentration improvement caused by the control measures ($\mu\text{g}/\text{m}^3$). Utilizing models in a relative sense to assess the efficiency of emission controls on air quality is common practice in regulatory modelling, with the assumption that there may be biases in the absolute concentrations simulated by a modelling system, but that the relative response of that system will reflect the response observed in the atmosphere (US EPA, 2014).

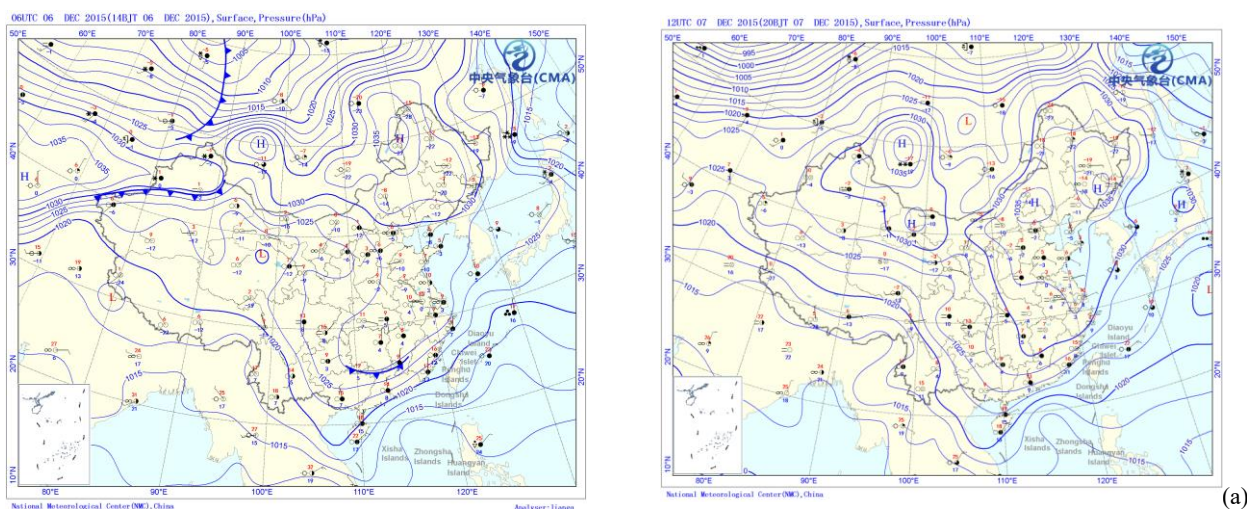

3 Results and discussion

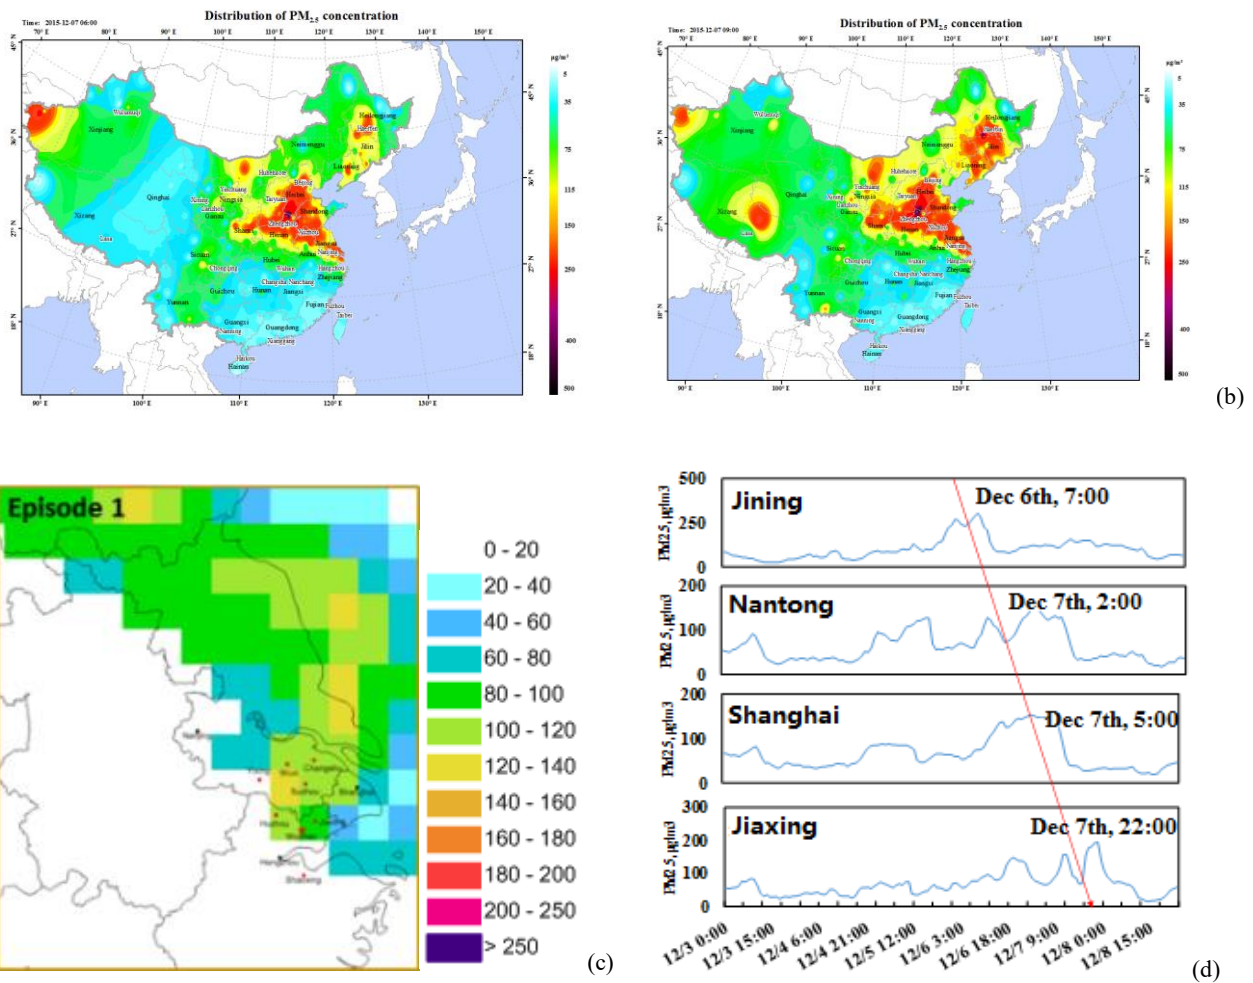

228 3.1 Photochemical transformation changes of air pollutants during the campaign

229 Ground observational data show that from December 1 to December 23, Jiaxing City experienced four distinct
230 physical and chemical processes that contributed to the observed pollution levels at different periods. For each of
231 these processes, this study utilized the integrated emission-measurement-modeling method to analyze the evolution
232 of air quality from several aspects, including the backward air flow trajectory, potential contribution source areas,
233 meteorological conditions and the variation of PM_{2.5} concentration.

234 3.1.1 Pollution process before the campaign with local emission accumulation as the main contributor

235 The first time period of interest was from December 6 to December 8. Analysis about the potential source
236 contribution areas resulting from PSCF modelling suggests that the polluted air mass primarily originated from the
237 northwest and northerly airstreams, passing Shandong, the eastern coastal areas of Jiangsu and Shanghai and into
238 northern Zhejiang, as is shown in Fig. 4. Analysis of the large-scale weather patterns showed that the polluted air
239 mass occurred in Beijing, Tianjin, Shandong peninsula and northern Jiangsu as a result of cold air with polluted air
240 mass transported into the region on the morning of December 5. In the southern part of Shandong province, the
241 PM_{2.5} concentration peak appeared on the morning of December 6, while the PM_{2.5} concentration peak appeared
242 around midnight on December 7 at the coastal area of Jiangsu. On December 6, the development of warm and humid
243 air flow, resulted in increasing ground humidity, which contributed to the growth of secondary fine particles and
244 the gradual accumulation of polluted air mass in northern Zhejiang and the surrounding areas of Shanghai. On
245 December 7, affected by the surface high-pressure system, the spread of plume was slow, and the spatial extent of
246 the plumes in northern Zhejiang expanded. Therefore, during this time period, the pollution was primarily affected
247 by regional transport and worsened by stagnant local conditions in Jiaxing.

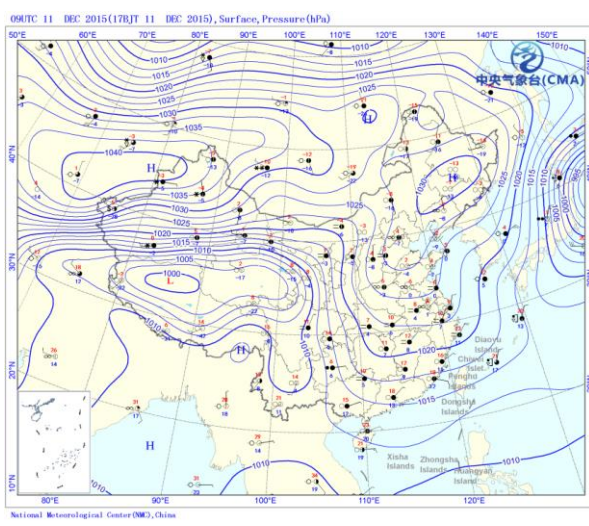

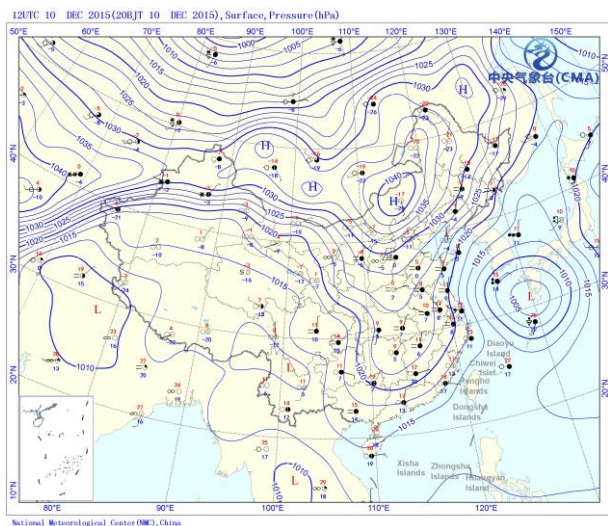

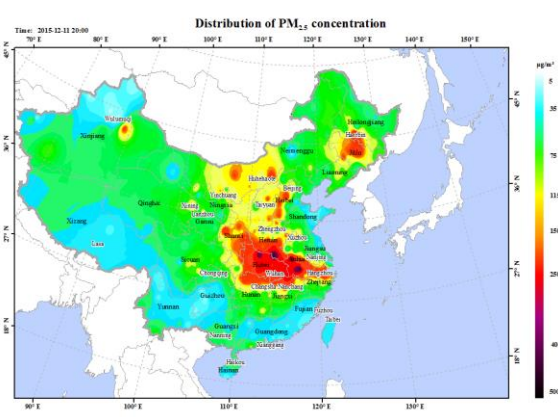

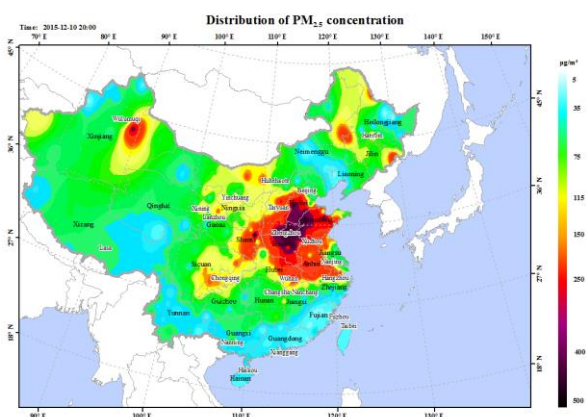

248 Fig. 4 Analysis of (a) the large-scale weather patterns, (b) distribution of $PM_{2.5}$ concentrations, (c) potential source regions, (d)
 249 Observed $PM_{2.5}$ time series for selected sites during December 6 to December 8, 2015

250 **3.1.2 Pollution process during the campaign with the southward motion of the weak cold air**

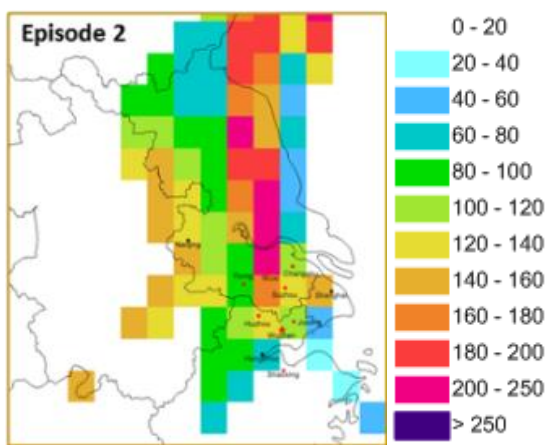

251 The second time period of interest was from December 10 to December 11. Analysis about potential source
 252 contribution areas suggests that the polluted air mass mainly came from northern regions, passing from south-eastern
 253 Shandong peninsula and central-eastern Jiangsu to northern Zhejiang. From the large-scale weather pattern, the
 254 diffusion of weak cold air on December 10 gradually transported the polluted air mass in the upper reaches of the
 255 region to the YRD region. The pollution peaked in areas such as Lianyungang in northern Jiangsu on the evening
 256 of December 10. On December 11, the $PM_{2.5}$ concentration peak appeared in central and southern Jiangsu as a result
 257 of northern weak air flow. The plume was further transported into Zhejiang province with the expansion in
 258 influenced areas as is shown in Figure 5. Therefore, the pollution process was mainly affected by the transport of
 259 polluted air mass caused by the southward motion of cold air.

 261 Observed PM_{2.5} time series for select sites during December 10 to December 11, 2015

262 **3.1.2 Heavy pollution process during the campaign with the transit and transport of strong cold air**

263 The third period of interest was from December 13 to the early hours of December 16. Analysis of the potential
 264 source contribution areas suggests that the polluted air mass mainly came from the northwest direction, passing
 265 through south-eastern Shanxi, western Shandong, eastern Anhui and western Jiangsu to Zhejiang province. On
 266 December 14, affected by the cold air transport in the north, northern plumes hit Hebei, Henan and Anhui provinces,

267 with the highest degree of pollution on the 14th. On December 15, the further spread of cold air caused the transport
 268 of plumes into Jiangsu and Zhejiang. The northern part of Zhejiang province was in the centre of pollution on the
 269 15th, which worsened the pollution and expanded the scope of pollution, as is shown in Figure 6. On December 16,
 270 under the control of the high-pressure system in northern Zhejiang, the air mass gradually moved eastward and the
 271 air quality improved in the morning. Therefore, for this time period, large-scale transport was the main factor leading
 272 to the increase in pollutant levels.

273

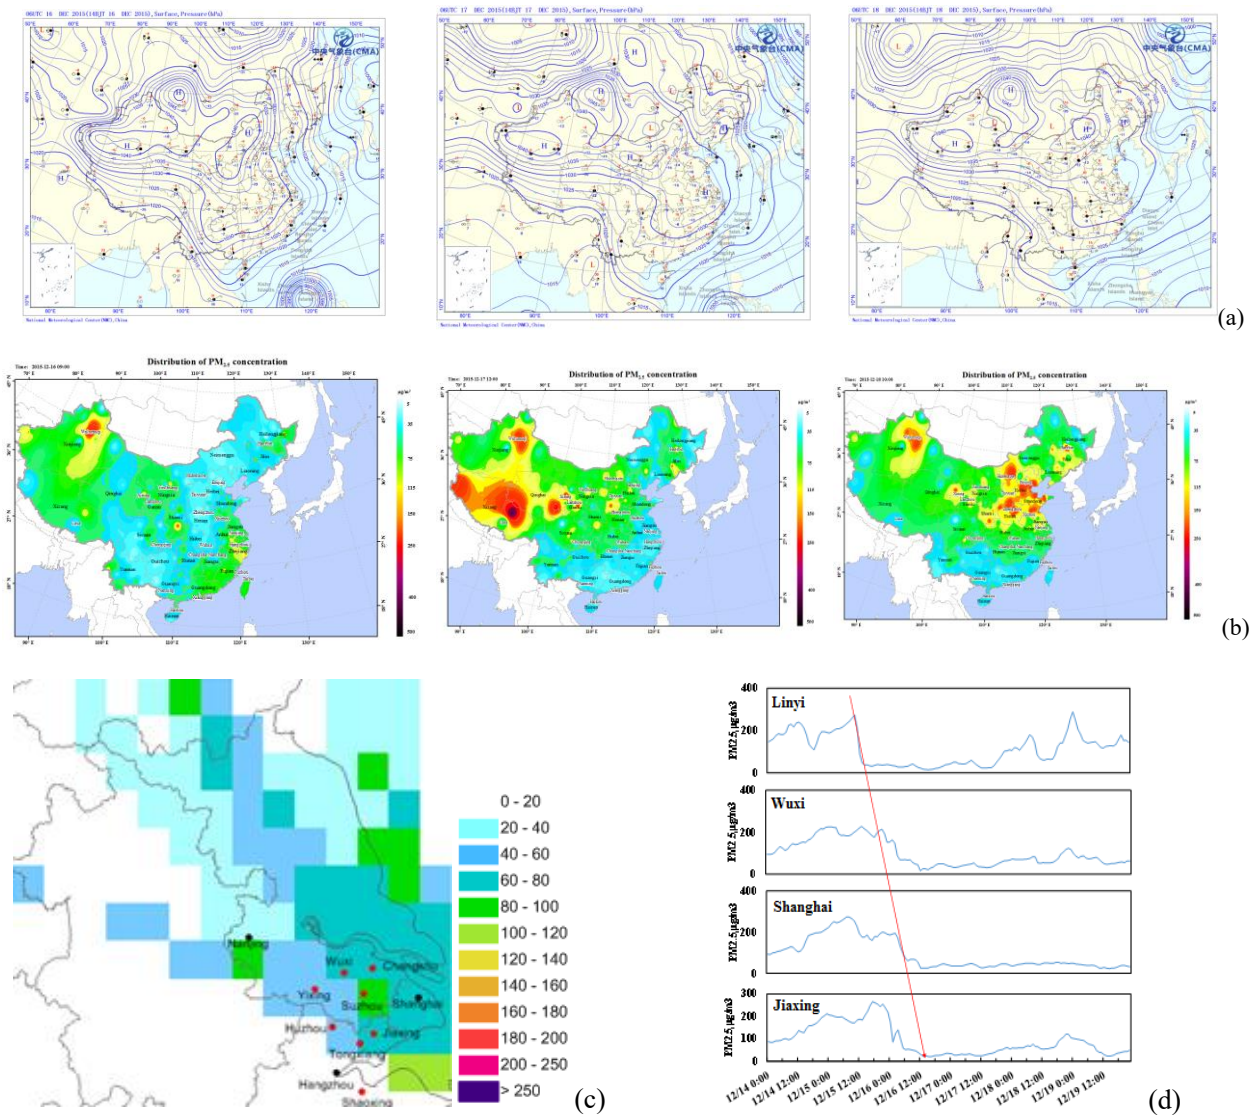

274 Fig. 6 Analysis of (a) the large-scale weather patterns, (b) distribution of PM_{2.5} concentrations, (c) potential regional sources, (d)
 275 Observed PM_{2.5} time series for select sites during December 14 to December 16, 2015

276 **3.1.3 Pollution removal process caused by clean cold air during the conference**

277 During the conference from December 16 to December 18, weather was affected by the large-scale southward
 278 transport of cold dry air in northern Zhejiang, resulting in lower temperature and relative humidity, as well as a
 279 significant improvement in the air quality. On the 17th and the 18th, under the control of a high pressure system in

280 northern Zhejiang, the sea level pressure increased, the humidity was lower and the wind speed was reduced.
 281 Because of the emission reduction effect of the control measures, the pollutant accumulation rate was likely slowed
 282 down and the air quality in northern Zhejiang was good overall. From the analysis of potential sources, PM_{2.5}
 283 concentrations in Shandong, Jiangsu and Shanghai were significantly reduced. The PM_{2.5} concentration during the
 284 conference was mainly controlled by local emissions, as is shown in Figure 7.
 285

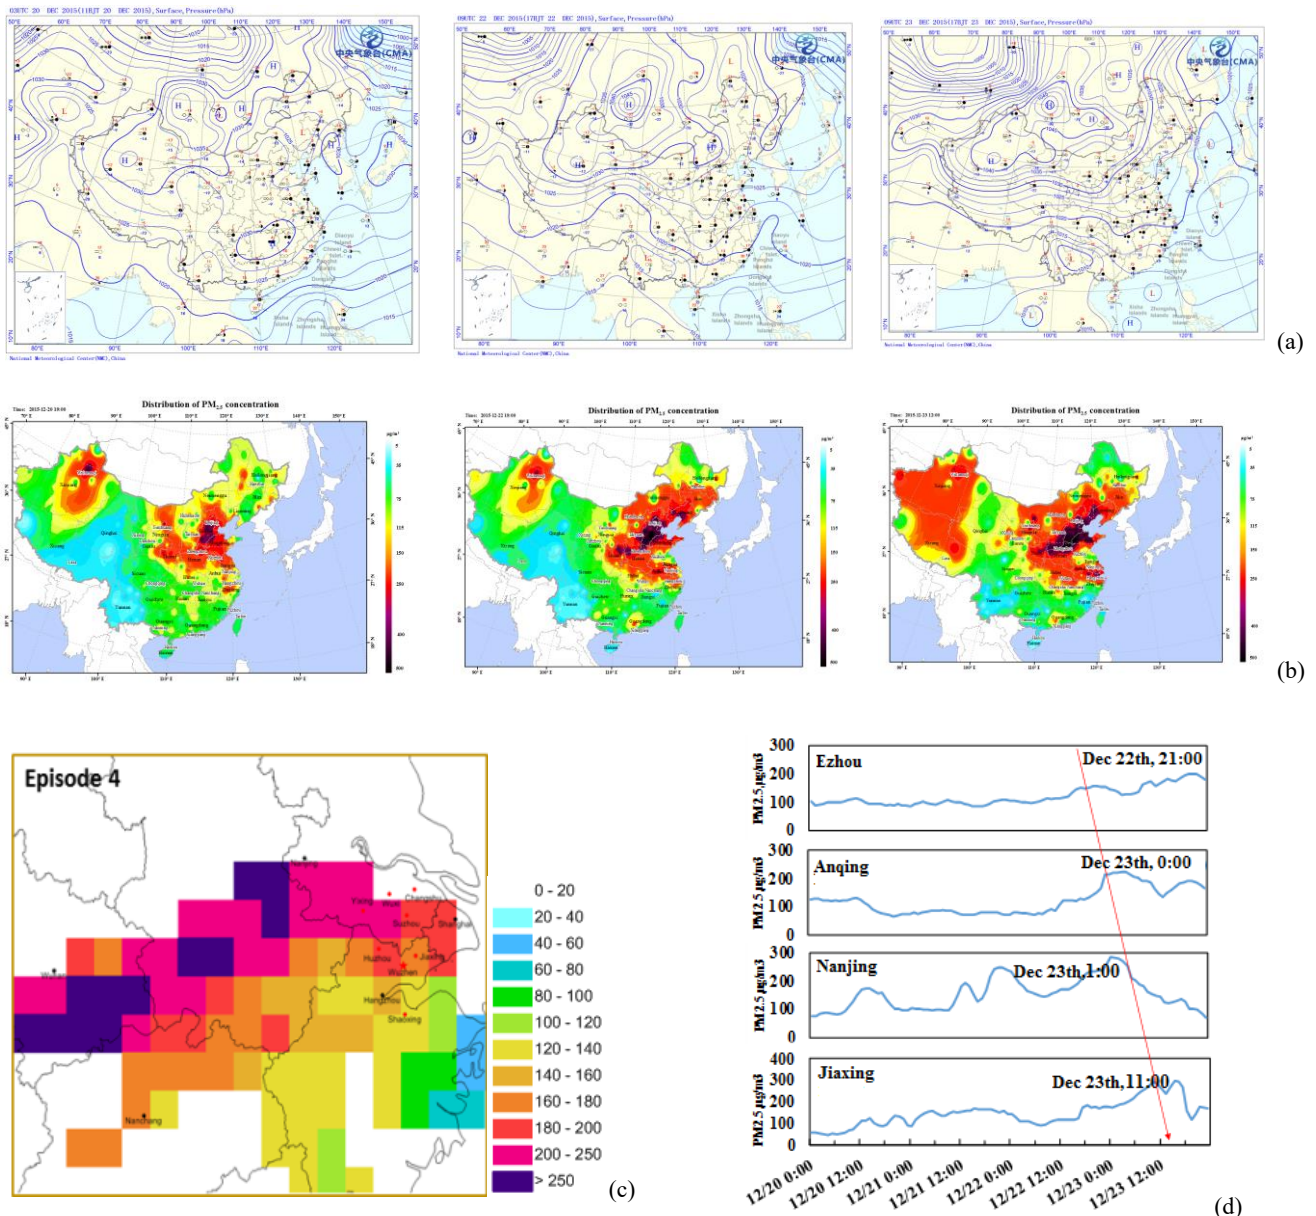

286 Fig. 7 Analysis of (a) the large-scale weather patterns, (b) distribution of PM_{2.5} concentrations, (c) potential regional sources, (d)
 287 Observed PM_{2.5} time series for select sites during December 16 to December 18, 2015

288 3.1.4 Pollution process after the campaign with local emission accumulation as the main contributor

289 The fourth period of interest was from December 20 to December 23. Analysis of the potential source
 290 contribution areas suggests that the polluted air mass mainly came from the southwest direction, passing through
 291 southern Hubei, southern Anhui and south-western Jiangsu to northern Zhejiang. On December 20, controlled by a
 292 stagnant air mass, Zhejiang province has a relatively low near-surface wind speed and little dispersion, resulting in
 293 the accumulation of local pollutants. On December 21, northern Zhejiang was located in the centre of a high pressure

294 system with conditions conducive to little mixing, and therefore polluted air mass occurred in some areas in northern
 295 Zhejiang. On December 22, affected by the warm and humid southwest air flow, Zhejiang had experienced some
 296 precipitation but the pollution in northern Zhejiang was not improved due to deep polluted air masses. In Hubei and
 297 Anhui located in the southwest of Jiaxing City, high pollution levels appeared from the evening of December 22 to
 298 the early hours of December 23, as is shown in Figure 8. On December 23, the further expansion of polluted air
 299 masses resulted in serious pollution in Jiangsu and northern Zhejiang. In general, under these heavily polluted
 300 conditions, the local accumulation of pollutants was mainly caused by stagnant conditions with little dispersion and
 301 transport within southwest air stream.

302 Fig. 8 Analysis of (a) the large-scale weather patterns, (b) distribution of PM_{2.5} concentrations, (c) potential regional sources, (d)
 303 Observed PM_{2.5} time series for select sites during December 20 to December 23

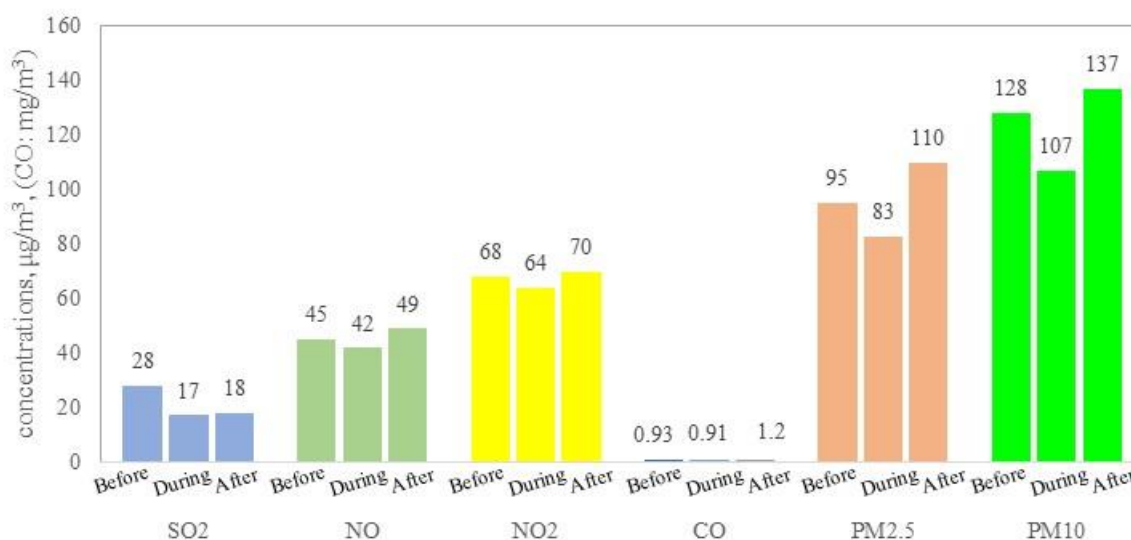

304 **3.2 Air quality changes under the same meteorological conditions before and after the campaign**

305 **3.2.1 Air quality changes under static meteorological conditions before and during the campaign**

306 During the air pollution control campaign for the conference, air quality in Jiaxing City fluctuated greatly due
 307 to the frequent southward motion of cold air from the north. Under static weather conditions, sources of atmospheric
 308 pollution mainly came from the accumulation of polluted air masses from local sources and sources in neighbouring
 309 areas. Therefore, in order to eliminate the influence of the transport process of the air mass, this study compared the
 310 air quality status before, during and after the campaign in Jiaxing City under stagnant weather conditions (wind
 311 speed less than 1m/s) and assessed the impact of control measures on ambient air quality in Jiaxing based on air
 312 quality observation data.

313 Figure 9 shows the concentration levels of criteria pollutants including SO₂, NO, CO, NO₂ and PM_{2.5} in Jiaxing
 314 City before (December 1-7), during (December 8-19) and after the regulation (December 19-31) under stagnant
 315 weather conditions. It can be seen that pollutant concentrations during the campaign were less than those before the
 316 campaign, in which SO₂ had the most significant decline of 40.1%, NO_x, CO, PM_{2.5} and PM₁₀ declined 8.0%, 2.6%,
 317 12.5% and 16.3%, respectively, indicating that control measures have significantly improved the air quality in
 318 Jiaxing City, especially with respect to SO₂ and PM₁₀.

319 After the campaign, all the pollutant concentrations rebounded sharply. SO₂, NO, NO₂, CO, PM_{2.5}, PM₁₀
 320 increased 8.3%, 15.4%, 10.3%, 31.8%, 32.2% and 28.6%, respectively. Concentrations of some pollutants were
 321 even higher than those before the campaign, which suggests that the emission intensity of the sources had
 322 significantly increased after the campaign.

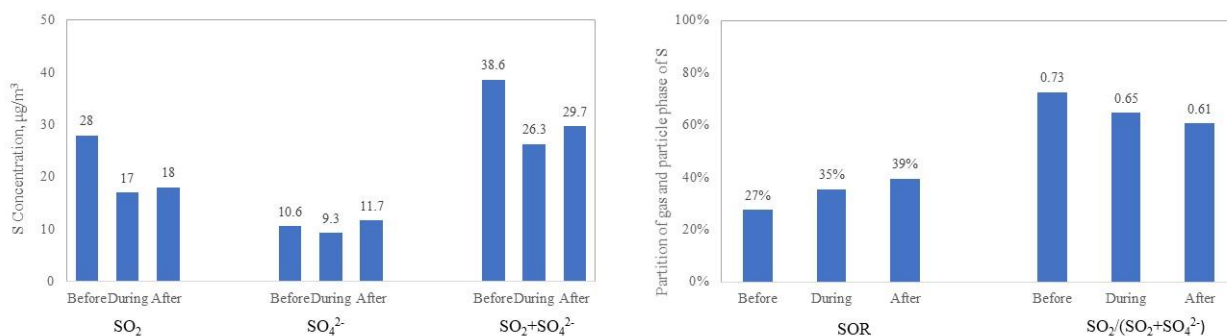

323
 324 Fig. 9 Comparison between air pollutant concentrations at Shanxi station before, during, and after the campaign under stagnant
 325 meteorological conditions

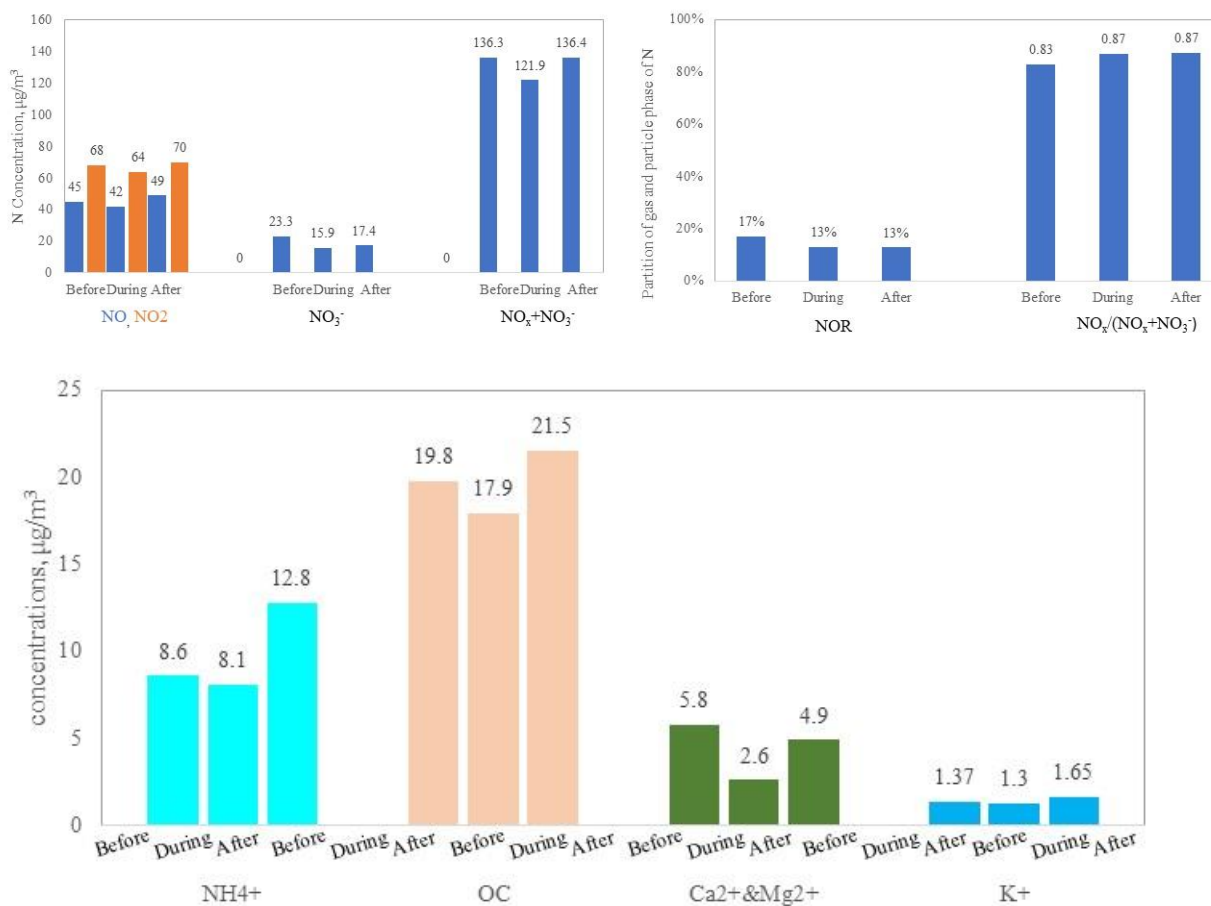

326 There are also some differences in concentrations of major chemical components of PM_{2.5} in Jiaxing City
 327 before (December 1-7), during (December 8-19) and after the campaign (December 19-31) under static weather

328 conditions, as shown in Figure 9. The concentrations of major chemical components of PM_{2.5} during the campaign
 329 were less than those before the campaign, which is consistent with the conclusion about changes in criteria pollutant
 330 concentrations. On average, SO₄²⁻, NH₄⁺, NO₃⁻, OC, mineral soluble irons (Ca²⁺ and Mg²⁺) and K⁺ declined 11.8%,
 331 5.1%, 32.1%, 9.8%, 56.8% and 5.1%, respectively. Comparisons between the distribution of PM_{2.5} chemical
 332 components before and during the campaign under static conditions suggest that Ca²⁺ and Mg²⁺ decreased most
 333 significantly during the control period, which indicates that the suspension of construction operations which result
 334 in dust emissions and the rising frequency of rinsing and cleaning paved roads, significantly reduced dust emissions.
 335 During the campaign, NO₃⁻ significantly decreased, indicating that vehicle control measures successfully reduced
 336 NO_x emissions and subsequently the formation of inorganic aerosols. The significant decrease in SO₄²⁻ also shows
 337 that restricting or suspending the operation of coal-burning power plants and industries in local and neighbouring
 338 cities played a very positive role.

339 Both the chemical compositions of PM_{2.5} and chemical processes associated with PM_{2.5} production change if
 340 we compare observed data during and after the regulation. As is shown from figure 10, the SO₂ concentrations after
 341 control is a little bit higher than during control (+5.9%). However, the SO₄²⁻ after control is much higher than during
 342 control (25.8%). This is probably due to two reasons: firstly, SO₂ emissions and primary sulfate emissions increased
 343 after the control measures were terminated; secondly, previous studies have reported that increased NO_x emissions
 344 could accelerate the formation of secondary sulfate (Cheng et al., 2016). This can be clearly seen from the SOR. A
 345 different trend is observed for NO₂ and NO₃⁻, with the NO₂ concentrations after control being much higher than
 346 during control (+9.4%), while the increase of NO₃⁻ (+9.45%) is about the same. Sulfate originates from both primary
 347 emissions and secondary formation, but nitrate is mostly secondary. The NOR during and after regulation is about
 348 the same and most of the N is in the gas phase as indicated by NO_x/(NO_x+NO₃⁻) (0.87). Therefore, the increase of
 349 NO₃⁻ is smaller than SO₄²⁻. The PM_{2.5} concentration after control sharply rebounded by 31.8%, indicating that both
 350 primary emissions and secondary formation are activated.

In order to distinguish the impact of meteorological conditions on air quality in Jiaxing City and better analyze the effects of control measures on air quality during the conference, this study has combined meteorological conditions with backward air flow trajectory analysis and carried out a comparative study by selecting a relatively similar pollution period before and during the campaign. The first period occurred before the campaign from 12:00 December 2 to 20:00 December 4, while the second period occurred during the campaign from 9:00 December 16 to 5:00 December 18. Both of these periods were relatively unaffected by long-range transport of plumes into the study area, and have similar backward airflow trajectories and meteorological conditions. Table 3 and Figure 11 compare average mass concentrations of pollutants (SO₂, NO_x, PM_{2.5} and PM₁₀) during these two periods. As can be seen from the figure, SO₂, PM_{2.5} and PM₁₀ decreased during the campaign by roughly 46%, 13% and 27%, respectively, while NO_x exhibited only a small decrease. This shows that without the impact of long-range transport, emission reduction measures carried out by local and surrounding cities play a significant role in defining the air quality in Jiaxing.

Table 3 Concentrations of major pollutants under similar meteorological conditions before and during the campaign

Period	Time	Wind speed m/s	Wind direction °	Relative humidity %	Temperature °C	Pressure hPa	Visibility km	SO ₂ µg/m ³	NO ₂ µg/m ³	PM ₁₀ µg/m ³	PM _{2.5} µg/m ³

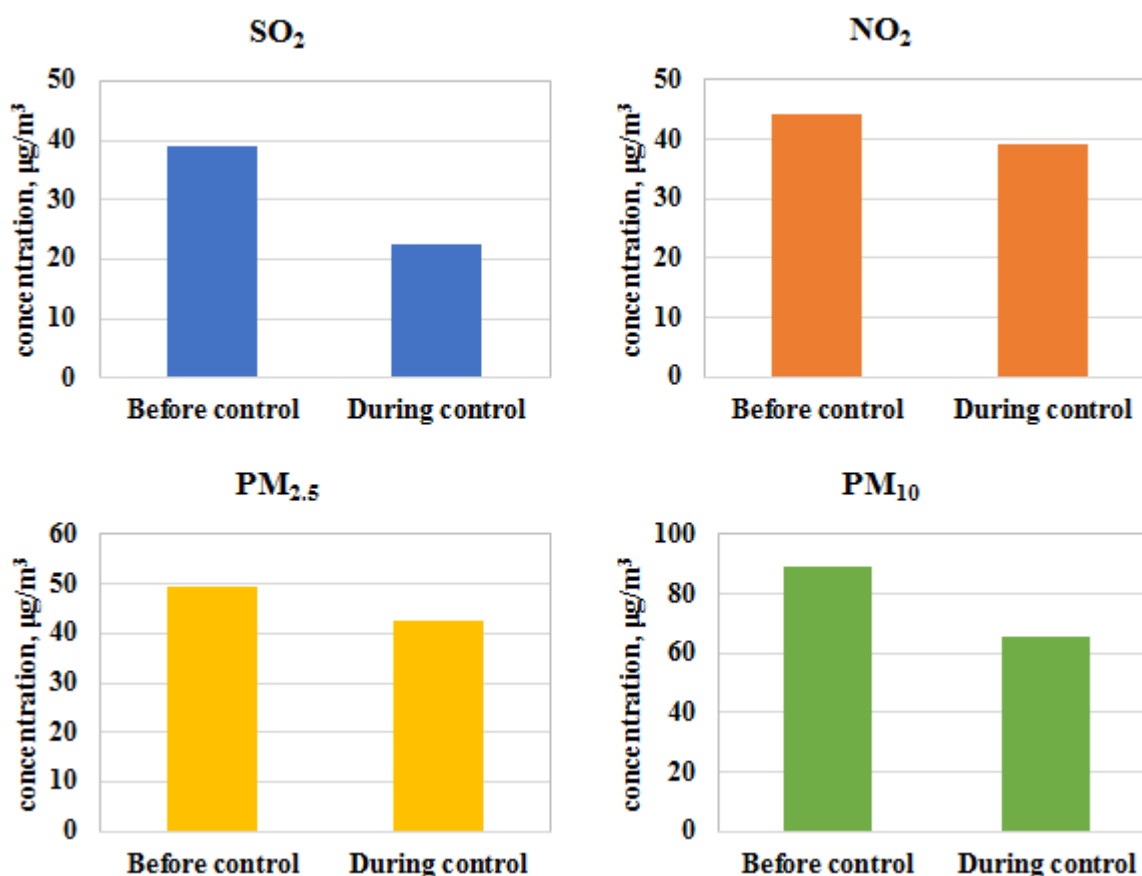

Fig. 11 Comparison between concentrations of major air pollutants in Jiaxing before and after the campaign under same meteorological conditions

371
372
373
374

375 There were two regional pollution episodes that occurred during the campaign. The first was on December 10-
376 12 caused by the southward motion of northern weak cold air. Polluted air masses from south-eastern Shandong
377 peninsula passed through central eastern Jiangsu and into northern Zhejiang, affecting the air quality in Jiaxing.
378 During this period, the average daily PM_{2.5} concentration in Jiaxing was 145.7 µg/m³, higher than the regional
379 average, and its major chemical components were nitrate (31%), sulphate (18%), ammonium (13%) and organic
380 carbon (13%), with obvious regional secondary pollution characteristics.

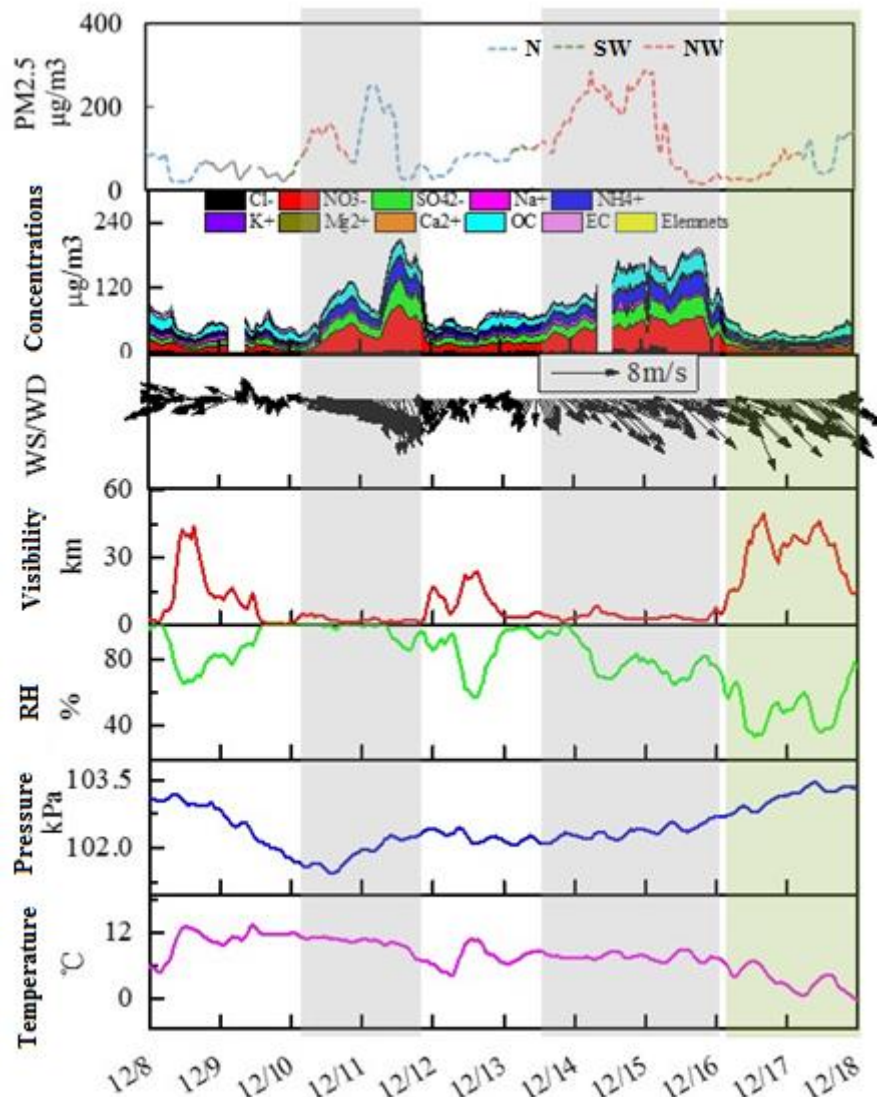

Fig.12 Changes in air quality and meteorological parameters in Jiaxing City during the campaign

381
382

383 The second episode occurred from December 14-15, and was caused by the transit of northwesterly strong cold
 384 air. Polluted air masses came from the northwest direction, moved rapidly to the southeast, passed through Shanxi,
 385 Hebei, west Shandong, east Anhui and west Jiangsu and ultimately into Zhejiang province. The air masses left
 386 China through south-eastern Zhejiang on the early morning of the 16th. The YRD region was strongly affected by
 387 the transport of the polluted air mass, with heavy polluted air masses appearing and lasting for about one day over
 388 the YRD region from north to south. PM_{2.5} peaked in Jiaxing on the 15th with a daily average of 201.6 µg/m³. The
 389 main chemical components of PM_{2.5} during the episode were nitrate (25%), sulphate (14%), ammonium (12%) and
 390 organic carbon (13%), which is consistent with an aged air mass as well as regional secondary pollution
 391 characteristics.

392 The regional linkage was initiated from December 16 to December 18, combined with favourable mixing
 393 conditions brought by the cold front. The overall air quality in the YRD region during this time period was good,
 394 with an average daily PM_{2.5} concentration in Jiaxing of 45 µg/m³. The major chemical components during this

395 cleaner period were organic carbon (26%), nitrate (16%), ammonium (12%), sulphate (9%) and other components
396 (37%), with some newly formed particles and no obvious regional transport, suggesting that air pollutants were
397 mainly derived from local emissions.

398 **3.3 Emissions reduction estimation during the campaign**

399 The air quality assurance campaign for the 2nd World Internet Conference was from December 8 to December
400 18. In order to ensure the air quality during the conference, three provinces and Shanghai municipality in the YRD
401 region carried out joint control measures. Based on the implementation of control measures in all areas during the
402 conference and whether each area had effectively implemented control measures during December 8-18, regional
403 emission reductions have been assessed. It is estimated that emission reductions of SO₂, NO_x, PM_{2.5} and VOCs
404 caused by production restriction in regional industrial enterprises are 2867.8 tons, 3064.7 tons, 2165.5 tons and
405 5055.4 tons, respectively. Emission reductions of various pollutants caused by the restrictions on motor vehicle
406 traffic are estimated to be 4.7 tons of SO₂, 326.9 tons of NO_x, 36.1 tons of PM_{2.5} and 452.5 tons of VOCs. Emission
407 reduction of PM_{2.5} caused by dust control was estimated to be 266.0 tons. Therefore, it can be seen that emission
408 reductions mainly come from industrial sources, while motor vehicle restrictions contributed greatly to emission
409 reductions of NO_x and VOCs, and dust control contributed 10% to emission reductions of PM_{2.5}.

410 When looking at specific industries, the power plants contributed most to the emission reductions of SO₂ and
411 NO_x at 49.7% and 46.9%, respectively, followed by the chemical industry, building materials industry, steel industry
412 and petrochemical industry with a total contribution from all four sectors to emission reductions of SO₂ and NO_x of
413 42.0% and 47.2%, respectively. For PM_{2.5}, the building materials industry contributed the most at 62.0%, followed
414 by steel and processing industry, power industry and non-ferrous smelting and process industry with a contribution
415 of 14.3%, 13.1% and 8.1%, respectively. For VOCs, the emission reduction sectors are mainly chemical,
416 petrochemical and machinery manufacturing sectors with a total contribution of 65.7% and individual contributions
417 of 25.1%, 23.2% and 17.4%, respectively. In addition, metal products processing, building materials and steel and
418 processing sectors also contributed significantly to emission reductions of 13.4%, 8.0% and 6.5%, respectively.

419 In terms of the regional distribution of emission reductions, Jiaxing, Hangzhou, Suzhou and Shaoxing have the
420 largest contribution of around 80%. These four cities contribute 87% to the total emission reduction of PM_{2.5}.

421 Combing all control measures, total emission reductions of SO₂, NO_x, PM_{2.5} and VOCs are estimated to be
422 2872.5 tons, 3391.6 tons, 2467.6 tons and 5507.9 tons, respectively, which accounts for 10%, 9%, 10% and 11%,
423 respectively, of the total urban emissions. It is worth mentioning that if we consider the emergency emission
424 reduction measures for heavy pollution during the campaign, the amount of emission reduction for all pollutants

425 and the proportion of their emission reductions would be even larger. Table 4 shows the percentage and the amount
 426 of emission reductions for pollutants under various control measures.

427
 428

Table 4 Emission reduction estimations for various control measures

Province	City	Sector	Amount of emission reduction (tons)				Percentage of reduction			
			SO ₂	NO _x	PM _{2.5}	VOCs	SO ₂	NO _x	PM _{2.5}	VOCs

429
 430

3.4 Quantitative estimates of the contribution of control measures to air quality improvement

3.4.1 PM_{2.5} concentration improvement in Jiaxing

432 The WRF-CMAQ air quality model, combined with observations, was used to evaluate the improvement of
 433 PM_{2.5} in Jiaxing due to the emission reductions achieved through the campaign. This analysis utilized two model
 434 simulations to assess the impact of the emission reductions: 1) a baseline scenario, which utilized an uncontrolled
 435 emission inventory (i.e., the emissions that would have occurred without the campaign), and 2) an emission
 436 inventory, which reflects the emission reductions achieved by the campaign. Figure 13 shows the time series of
 437 PM_{2.5} observed concentrations and the percent change in PM_{2.5} after the air quality control measures were
 438 implemented. It can be seen that the PM_{2.5} decline ratio in Jiaxing varies with time. The PM_{2.5} decline ratio was

439 most significant during December 8-9 with a maximum reduction of 56%. During the campaign from December 8
 440 to December 18, average PM_{2.5} concentrations decreased by 10.5 µg/m³ with an average decrease of 14.4%.
 441 However, Although there are many control strategies implemented, the effects during 12/14-12/16 are low. As
 442 described in section 3.1.2, the prevailing wind direction during this period is NW, and Jiaxing experienced a heavy
 443 pollution process with the transit and transport of strong cold air. Therefore, we can not see obvious effect without
 444 strong upwind precursor emissions reductions.

445
 446 Fig. 13 Time series of observed PM_{2.5} and the percentage reduction resulting from the implementation of air quality control measures

447 Figure 14 shows the reduction in daily average PM_{2.5} concentrations in Jiaxing resulting from the emission
 448 reductions associated with the Action Plan for Air Quality Control during the World Internet Conference. As can
 449 be seen from the figure, the improvement in PM_{2.5} before the conference (December 8 and 9) was relatively
 450 significant, with a daily average decline of roughly 31% and 35%, respectively, which corresponds to a decrease of
 451 around 17 µg/m³. The reduction in PM_{2.5} during December 14-15, two of the days with some of the highest observed
 452 PM_{2.5}, was relatively low at around 6%, while daily average PM_{2.5} concentrations on those days decreased by around
 453 10.0 µg/m³. The magnitude of emission reductions during those two time periods was basically the same, so it's
 454 likely that the observed difference in PM_{2.5} levels was the result of meteorological differences, and in particular,
 455 enhanced transport of polluted air into Jiaxing from December 14 to 15. Overall, under the influence of regional
 456 control measures for emission reductions from December 8 to December 18, PM_{2.5} daily average concentration
 457 decreased by 5.5%-34.8% with an average of 14.6% or 10 µg/m³.

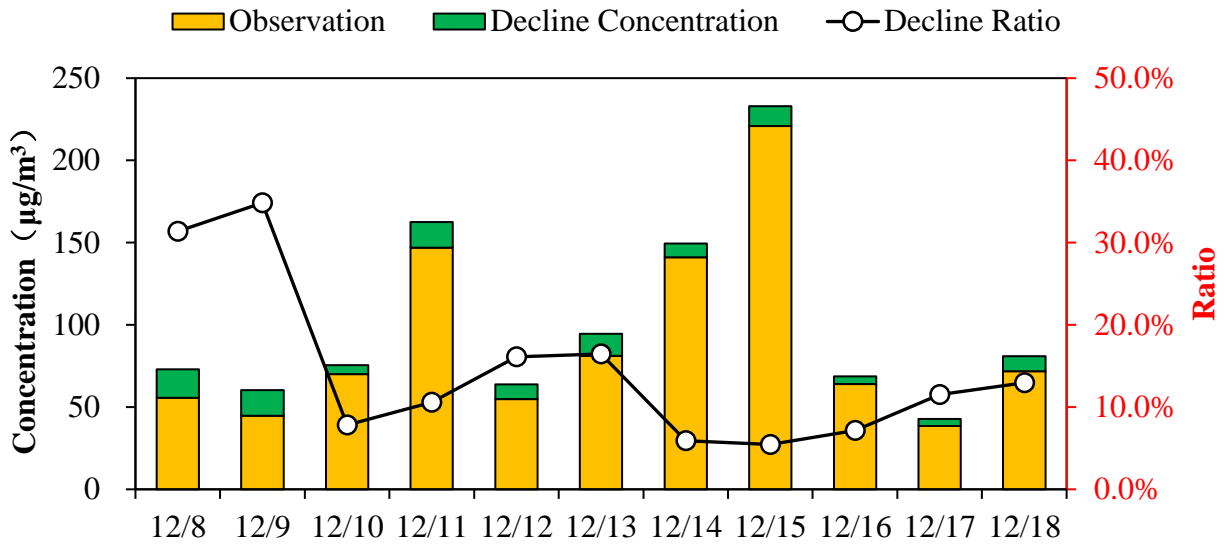

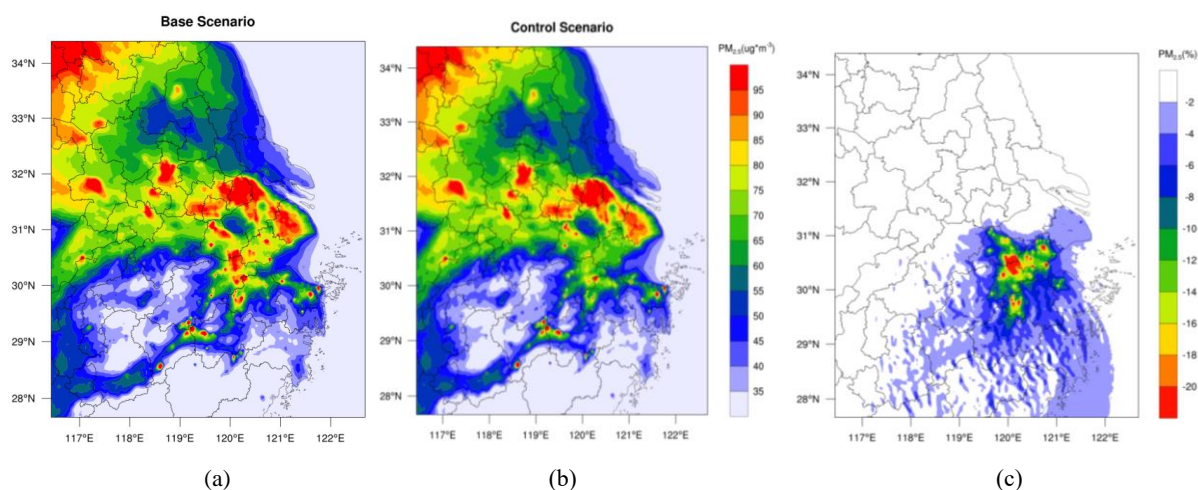

Fig.14 Percentage reduction in PM_{2.5} resulting from the control measures

458
459

460 The decline ratio changes with meteorological conditions even under the same emissions reduction situation,
 461 because meteorological conditions influence dispersion from primary emissions, regional transport and secondary
 462 formation. The magnitude of emission reductions during those two time periods was basically the same, so it is
 463 possible that the observed difference in PM_{2.5} levels was the result of meteorological differences. Overall, the
 464 residual PM_{2.5} may come from three aspects: (1) although stringent control measures have been implemented, there
 465 are still some precursor emissions in the city, which accumulated and formed secondary particles under favorable
 466 meteorological conditions; (2) enhanced transport under specific meteorological conditions, especially upwind
 467 emissions; (3) in view of the uncertainties of model performance (underestimation of PM_{2.5}, especially
 468 underestimation of SOA) described in previous sections, it should be noted that the secondary formation may
 469 probably be underestimated, causing modeled decline ratio lower than observed.

470 3.4.2 PM_{2.5} concentration improvement across regions

471 Figure 15 shows the spatial distribution of PM_{2.5} concentrations in the Yangtze River Delta region from
 472 December 8 to December 18 in the baseline scenario and the campaign scenario. As can be seen from the figure,
 473 southern Jiangsu, Shanghai and northern Zhejiang in the central YRD region had relatively high PM_{2.5}
 474 concentrations, which is consistent with the typically more serious pollution levels in autumn and winter in the YRD
 475 region. Under the influence of regional control measures, PM_{2.5} average concentrations declined significantly in
 476 Jiaxing, Hangzhou and Huzhou, especially at the junction of these three cities, with a slight improvement in central
 477 southern Zhejiang as well. The average percentage PM_{2.5} decline ratio in Jiaxing, Hangzhou and Huzhou was about
 478 6%-20%. Meanwhile, given that the prevailing winds are north-westerly in winter, there was also some
 479 improvement in central and southern Zhejiang.

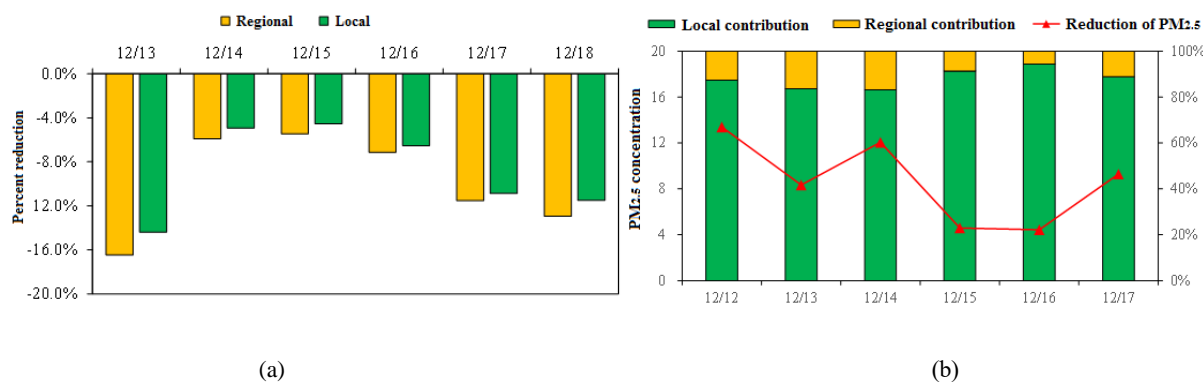

480
481
482 Fig. 15 Spatial distribution of PM_{2.5} concentrations in the Yangtze River Delta region under the baseline scenario (a) and the
483 campaign scenario (b), and the percentage reduction in PM_{2.5} throughout the YRD region (c)

484 3.4.3 Regional contributions of PM_{2.5} concentration improvement in Jiaxing

485 Figure 16(a) shows the percentage reduction in PM_{2.5} daily average concentrations from December 13 to
486 December 18 after control measures were implemented in Jiaxing and regionally. The reduction in PM_{2.5} was the
487 results of both local controls, as well as regional controls which reduced pollution in the air masses transported into
488 Jiaxing. Overall, modelling suggests that the regional controls reduced PM_{2.5} levels in Jiaxing between 5.5%-16.5%
489 (9.9% average), while local control measures contributed 4.5%-14.4%, with an average of 8.8%.

490 Figure 16(b) shows the average contribution of local emissions reductions in Jiaxing and in the YRD region
491 over the entire campaign (Dec.13-18), as well as the corresponding improvement in PM_{2.5} levels in Jiaxing. During
492 this period, PM_{2.5} daily average concentration declined by 4-13 µg/m³, while there were differences in the
493 contribution of regional remission reductions and local emission reductions in Jiaxing during different periods.
494 Overall, local control measure in Jiaxing had the largest impact on PM_{2.5} levels and accounted for 89% of the decline
495 in PM_{2.5}, while regional control measures contributed the remaining 11%.

496
497
498 Fig. 16 Percentage reduction in daily average PM_{2.5} concentrations from December 13 to December 18 after implementation of the
499 control measures across the region and in Jiaxing (a) and Contribution of local and regional emissions reductions in Jiaxing, and the
500 resulting improvement of daily average PM_{2.5} concentrations in Jiaxing (b)

501 3.5 Optimisation scenario analysis of regional linkage control measures

502 **3.5.1 Optimization scenario settings**

503 In order to further analyse the optimisation potential of air quality control measures for major events and
 504 enhance the effectiveness of the control measure scheme design, three control measure optimisation scenarios have
 505 been set on the basis of the evaluation scenario (Base) after the implementation of air quality control measures
 506 during the conference. These scenarios include local emission reductions in Jiaxing under stagnant meteorological
 507 conditions, where local emission accumulation is the main contributor to the pollution process (Sce.1), and the
 508 emission reduction scenario where transport of polluted air masses into Jiaxing is a major contributor to the PM_{2.5}
 509 levels in Jiaxing. In order to investigate the transport processes further, the latter scenario was further divided into
 510 a scenario 24 hours in advance (Sce.2) and a scenario 48 hours in advance (Sce.3). Table 5 describes the details of
 511 each scenario.

512
 513

Table 5 Control measure optimization scenario settings

Scenario name	Scenario settings	Emission reduction regions	Emission reduction measures	Starting time
Base	Regional emission reduction	All the cities and areas involved in the campaign scheme	All control measures mentioned in the campaign scheme	December 8
Sce.1	Local emission reduction in Jiaxing	Jiaxing	Control measures in Jiaxing mentioned in the campaign scheme	December 8
Sce.2	Emission reduction through transport channels 24 hours in advance	Cities located in the northwest transport channel of Jiaxing	Cut down industrial sources by 30%	December 13
Sce.3	Emission reduction through transport channels 48 hours in advance	Cities located in the northwest transport channel of Jiaxing	Cut down industrial sources by 30%	December 12

514 Figure 17 shows the cities that primarily influence the polluted air masses transported into Jiaxing, where the
 515 transport channels were determined through backward trajectory analysis. These cities include Huzhou in Zhejiang
 516 province, Suzhou, Wuxi, Changzhou, Nanjing, Zhenjiang, Huai'an, Suqian and Suzhou in Jiangsu province and
 517 Suzhou, Huaibei, Bozhou, Bengbu, Chuzhou and Ma'anshan in Anhui province. Each of these cities took measures
 518 to reduce emissions by limiting production from industry industries by 30%.

Fig. 17 Cities involved in the transport channel and the emission reduction channel

519

520

The WRF-CMAQ modelling system was used to analyse and compare the air quality improvement effect under different pollution process in four scenarios.

521

522

523 3.5.2 Analysis of optimization scenario effects

In order to evaluate the effect of the different starting time for the same control measures, and the same starting time for local and regional control measures, we investigated four scenarios. Figure 18 shows the percentage reduction in daily average $PM_{2.5}$ concentrations in Jiaxing City from December 13 to December 18 under the regional emission reduction scenario, the Jiaxing local emission reduction scenario and the transport channel emission reduction scenario. Overall, there are differences in the distribution of $PM_{2.5}$ under the different scenarios. The air quality improvement due to the regional emission reductions was higher than that of local emission reductions in Jiaxing, and lower than that of channel emission reductions.

532

Fig. 18 Decline rates of $PM_{2.5}$ daily average concentrations in Jiaxing under different scenarios

533 **(1) Effect of local emission reductions in Jiaxing**

534 By comparing the effect of local emission reductions in Jiaxing (Sce.1) and the effect of regional emission
535 reductions (Base), we can see that PM_{2.5} daily average concentrations in Jiaxing declined by around 5.5%-16.5%
536 under the regional emission reduction plan (regional emission plan including the local emissions control) from
537 December 13 to December 18 and by around 4.5%-14.4% under the local emission reduction plan. Local emission
538 reductions in Jiaxing contributed 83%-94% to the emission reduction effect. Therefore, local emission reduction in
539 Jiaxing is the key factor in improving the local air quality.

540 Compared with the channel emission reduction scenario 24 hours in advance (11.6%-18.2%), local emission
541 reductions also contributed more than 50% to the improvement effect on December 13, 17 and 18. Therefore, local
542 emission reductions contributed most to the air quality improvement effect in Jiaxing, indicating that local areas are
543 still the most important control areas during the campaign.

544 **(2) Effect of emission reductions through transport channels**

545 As mentioned above, during the large-scale transport of heavily polluted air masses into the Yangtze River
546 Delta region from December 14 to December 15, the PM_{2.5} pollution in Jiaxing was significantly affected. Under
547 the local emission reduction scenario (Sce.1) and the regional linkage emission reduction scenario (Base), PM_{2.5}
548 daily average concentrations in Jiaxing decline by only 4.5%-5.9%. If a 30% reduction in emissions from industrial
549 sources in the upwind transport channel is implemented, PM_{2.5} daily average concentrations in Jiaxing declined by
550 11.6%-13.6%, while local emission reductions contributed less than 40% to the improvement of PM_{2.5}. Therefore,
551 to reduce PM_{2.5} under these large-scale transport conditions, in addition to intensifying local emission reduction
552 efforts, it is more effective to prevent and control such pollution by adopting emission reductions of industrial
553 sources over key transport channels, especially for elevated sources.

554 In this study, the main transport channel involved is the northwest transport channel in control areas, which
555 basically represents the typical winter transport channel in the region. In this study, the main transport channel
556 involved is the northwest transport channel in control areas, which basically represents the typical winter transport
557 channel in the region. Air quality improvement due to regional emission reductions was slightly larger than that of
558 local emission reductions in Jiaxing, and smaller than that of channel emission reductions. This suggests that
559 emissions reduction in the downwind cities does not have much effect on Jiaxing's air quality. In contrast, emissions
560 reduction based on predicted transport pathway in advance are much more effective than local emissions reduction
561 as well as regional emission reductions. Therefore, a well-designed management plan for the main transport channel
562 is necessary to ensure optimized air quality improvement in autumn and winter, in addition to reducing local

563 emissions.

564 (3) Effect of the starting time for channel emission reductions

565 According to the comparisons between the emission reduction scenario 24 hours in advance (Sce.2) and the
566 emission reduction scenario 48 hours in advance (Sce.3) during the large-scale PM_{2.5} transport, we can see that if
567 we take December 13 as the target and adopt channel emission reductions 48 hours in advance, PM_{2.5} daily average
568 concentrations will decline by 23.1% when compared to the baseline scenario, which is significantly better than the
569 improvement achieved by the emission reduction scenario 24 hours in advance (18.2%). Therefore, early measures
570 to reduce emissions will lead to the improvement of air quality.

571 If we focus on the conference period (December 16-18), PM_{2.5} daily average concentrations will both decline
572 by 15.3%-19.7% under the two channel emission reduction scenarios, indicating a close improvement effect.
573 Therefore, during the pollution process when local emissions are the main contributor, local emission reductions
574 should be the top priority with no difference between channel reductions 24 hours in advance and 48 hours in
575 advance. If transport is the main contributor to the pollution, adopting channel reductions 48 hours in advance can
576 bring about more improvement effect than 24 hours in advance.

577 4 Conclusions

578 (1) **The effect of restricting production in industrial enterprises is remarkable.** The power industry and
579 related industrial enterprises in Jiaxing cut down SO₂ and NO_x emissions by over 50%, while the building materials
580 industry, smelting industry and other industrial enterprises cut down PM_{2.5} emissions by 63%, contributing greatly
581 to the reduction of primary PM_{2.5} concentrations. The petrochemical industry, chemical industry and other related
582 industrial enterprises cut down VOCs emission by 66% in total, contributing greatly to the reduction of PM_{2.5} formed
583 through the conversion of precursor species. The observation data of PM_{2.5} components suggest that the relative
584 contribution of secondary components dropped significantly during the conference. Production restriction or
585 suspension for industrial enterprises is the main contributor to emission reductions for various pollutants during the
586 campaign, which resulted in the largest improvement in air quality.

587 (2) **Motor vehicle pollutant emissions declined significantly.** In Jiaxing, motor vehicle restrictions were fully
588 implemented during heavy pollution days, temporary traffic control was implemented during certain periods, and
589 enterprises and institutions had a three-day vacation during the conference. Emission reduction rates for various
590 pollutants from motor vehicle emissions were around 40%-50%. Motor vehicle emission reduction measures
591 contributed to the total emission reductions of nitrogen oxides by 18.2%, fine particles by 3.4% and volatile organic
592 compounds by 10.1%.

593 **(3) The effect of dust control measures is remarkable.** During the conference, most of the construction sites
594 in Jiaxing were suspended from operation. Increased frequency for road cleaning activities greatly lowered the dust
595 emissions. Speciation of the measured PM_{2.5} suggest that the mass concentration of crust material, decreased by 14%
596 compared to measurements after the conference. Specially, under static conditions, mineral soluble irons (Ca²⁺ and
597 Mg²⁺) declined 56.8% before and during the campaign. This suggests that the suspension of construction operations
598 and increased frequency of rinsing and cleaning of paved roads significantly reduced dust emissions.

599 **(4) Regional linkage between surrounding areas played an important role.** PM_{2.5} is a typical regional air
600 pollutant, with obvious regional transport characteristics. In accordance with the requirements of the campaign
601 scheme, eight cities around Jiaxing have actively implemented emissions reduction measures. During the campaign,
602 PM_{2.5} concentrations in eight surrounding cities and south-eastern Zhejiang also declined with obvious regional
603 synergies.

604 It is worth noting that the implementation of control measures has also had a negative impact on the economy
605 and the society in the short term while improving the air quality. For example, production restriction or suspension
606 on a large number industrial enterprises were taken at great economic costs, and motor vehicle restriction had a
607 large impact on the society.

608 **(5) Suggestions on emission reduction plans:** Local emission reductions shall be supplemented by regional
609 linkage. Assessment results show that local emission reductions play a key role in ensuring air quality. Therefore,
610 it is recommended that a synergistic emission reduction plan between adjacent areas with local pollution emission
611 reductions as the core part should be established and strengthened, and emission reduction plans for different types
612 of pollution through a stronger regional linkage should be reserved. Strengthen the pollution reduction in the upper
613 reaches along the transport channel. It is especially crucial to enhance pollution emission reductions in the upper
614 reaches of the channel since long-distance transport of plumes is a problem. This is especially true for key industrial
615 sources and elevated sources. Considering that polluted air mass transport is more frequent in winter, it is necessary
616 to develop emission reduction plans for different plume transport channels, combined with forecasting and warning
617 mechanisms which could be initiated on time.

618 619 **Author contribution**

620 L. Li designed this study and wrote the paper. H. L. Wang co-designed the study and provided valuable advice on
621 the data analysis. C. Huang developed the regional emissions inventory. S. H. Zhu performed observational data
622 analysis and J. Y. An carried out the CMAQ and CAMx modelling work. R. S. Yan performed the WRF modelling.
623 M. Zhou and L. P. Qiao helped observation and data quality control. X. D. Tian and L. J. Shen carried out the
624 measurements and provided the observed data. L. Huang and Y. J. Wang helped to revise the paper. Jeremy C. Aise

625 and Joshua S Fu helped revise and polish the manuscript and gave advices on paper writing.

626 **Competing interests**

627 The authors declare that they have no conflict of interest.

628 **Acknowledgements.**
