65 **Abstract.** The Atmospheric Pollution and Human Health in a Chinese Megacity (APHH-Beijing)
66 programme is an international collaborative project focusing on understanding the sources, processes and
67 health effects of air pollution in the Beijing megacity. APHH-Beijing brings together leading China and
68 UK research groups, state-of-the-art infrastructure and air quality models to work on four research themes:
69 (1) sources and emissions of air pollutants; (2) atmospheric processes affecting urban air pollution; (3)
70 air pollution exposure and health impacts; and (4) interventions and solutions. Themes 1 and 2 are closely
71 integrated and support Theme 3, while Themes 1-3 provide scientific data for Theme 4 to develop cost-
72 effective air pollution mitigation solutions. This paper provides an introduction to (i) the rationale of the
73 APHH-Beijing programme, and (ii) the measurement and modelling activities performed as part of it. In
74 addition, this paper introduces the meteorology and air quality conditions during two joint intensive field
75 campaigns - a core integration activity in APHH-Beijing. The coordinated campaigns provided
76 observations of the atmospheric chemistry and physics at two sites: (i) the Institute of Atmospheric
77 Physics in central Beijing, and (ii) Pinggu in rural Beijing during 10 November – 10 December 2016
78 (winter) and 21 May- 22 June 2017 (summer). The campaigns were complemented by numerical
79 modelling and automatic air quality and low-cost sensor observations in the Beijing megacity. In
80 summary, the paper provides background information on the APHH-Beijing programme, and sets the
81 scene for more focussed papers addressing specific aspects, processes and effects of air pollution in
82 Beijing.

83 **1. Introduction**

84 Air pollution is one of the largest environmental risks. It is estimated that air pollution has led to 7
85 million premature deaths per year globally (WHO, 2016a, b) and over a million in China (GBD MAPS

86 Working Group, 2016). Air pollution also has significant impact on the healthcare system and
87 ecosystems, which cost about 0.3% of global GDP (OECD, 2016). Air pollution related sickness also
88 reduces productivity and severe hazes lead to closure of transport systems, causing additional damage to
89 the economy. Total economic losses related to China's PM_{2.5} (particulate matter with aerodynamic
90 diameter equal to or less than 2.5 µm) pollution in 2007 amounted to 346 billion Yuan (£39 billion,
91 approximately 1.1% of the national GDP) based on the number of affected Chinese employees whose
92 work time in years was reduced because of mortality, hospital admissions and outpatient visits (Xia et
93 al., 2016).

94

95 Considerable research effort has led to huge progress in understanding the sources and pollution
96 processes in megacities in western countries, e.g., major interdisciplinary and multi-institutional
97 programmes in Paris and London in the last few years (Beekmann et al., 2015; Bohnenstengel et al.,
98 2014). Although air pollution in developed megacities sometimes breaks country specific limits and
99 WHO guidelines, traditional London or Los Angeles type smogs which occurred in the early and mid-
100 20th centuries are rare in developing cities to the same extent. In the developing countries however, the
101 rush to industrialisation and rapid growth in vehicle populations have led to serious air pollution
102 problems that are more complex than the London or Los Angeles smogs.

103 Air pollution is particularly severe in developing megacities, such as Beijing, where pollutants from
104 traditional sources, such as solid fuel combustion are mixed with those from modern vehicles (Guan et
105 al., 2014), on top of regional pollution from industrial and other anthropogenic activities. Air pollution
106 in Beijing is different to that in well studied developed megacities, such as Paris and London, in a
107 number of ways including the lack of diesel emissions in the inner city, the use of coal in surrounding
108 rural areas for heating and domestic cooking (Tao et al., 2018), the high emissions of air pollutants in
109 neighbouring provinces (Hebei and Tianjin) and the high oxidising power due to the complex chemistry
110 (Zhang et al., 2009; Li et al., 2017; Lu et al., 2018). This makes Beijing a particularly interesting place
111 to study as it provides an atmospheric environment with major contrasts to developed megacities such
112 as London and Paris in which to investigate urban pollution processes.

113 Many research programmes have been initiated in Beijing to study the air pollution processes since the
114 late 1990s. Earlier research programmes (e.g., early 2000) focused on primary emissions of SO₂, NO₂,
115 CO, PM₁₀, volatile organic compounds, and subsequently secondary pollutants such as ground-level
116 ozone and secondary fine particles. This research contributed to the development of air pollution
117 mitigation strategies introduced by the Beijing Municipal government.

118

119 The Beijing Olympic Games (2008) offered additional incentives to improve air quality and this led to
120 the funding of CAREBEIJING (Campaigns of Air Pollution Research in Megacity Beijing and
121 Surrounding Region) and other major programmes. The field campaigns were conducted in the summer
122 of 2006, 2007, and 2008, with the objectives to learn the environmental conditions of the region, to
123 identify and quantify the processes (transport and transformation) that led to the impact of the surrounding
124 area on air quality in Beijing, and to formulate policy suggestions for air quality improvement during the
125 2008 Beijing Olympic Games. Measures developed as a result of this and other programmes successfully
126 improved air quality during the Olympics Games, and provided valuable examples for developing air
127 pollution control policy in other cities (Wang et al., 2010). CARE-BEIJING was later extended to
128 CAREBEIJING-NCP (Campaigns of Air Pollution Research in Megacity Beijing and North China Plain),
129 in which field campaigns were carried out in the summer of 2013 and 2014 to investigate the transport
130 and transformation processes of air pollutants in the Beijing megacity and North China Plain. The results
131 of CAREBEIJING and CAREBEIJING-NCP have been published in three special issues of Atmospheric
132 Chemistry and Physics (https://www.atmos-chem-phys.net/special_issue198.html) and Journal of
133 Geophysical Research-Atmospheres
134 ([https://agupubs.onlinelibrary.wiley.com/doi/toc/10.1002/\(ISSN\)2169-8996.CARBS1](https://agupubs.onlinelibrary.wiley.com/doi/toc/10.1002/(ISSN)2169-8996.CARBS1)). However, our
135 understanding of sources and emissions of key air pollutants such as PM_{2.5} and ozone and the role of the
136 interactions between physical and chemical processes in the development of pollution events in Beijing
137 is still far from being accurate or complete. In addition, none of the abovementioned large programmes
138 have been directly linked to health effect studies.

139 The adverse health effects of air pollution provide one of the key motivations to control air pollution.
140 Research has shown that air pollution is one of the leading causes of the disease burden in China (GBD
141 MAPS Working Group, 2016). Especially, particulate pollution, the leading cause of severe air pollution
142 events in China, has a significant impact on human health and is associated with high mortality (Zhang
143 et al., 2017a), with a considerable proportion of this related to cardiorespiratory diseases (namely stroke,
144 ischemic heart disease, and chronic obstructive pulmonary disease) (Yang et al., 2013; Lozano et al.,
145 2013). Despite this increasing evidence base, the adverse health impact of air pollution remains a complex
146 issue. For instance, the risk assessment of disease burden due to air pollution in China has relied largely
147 on the studies undertaken in Europe and North America, which may be subject to error due to the
148 difference of race, life style, and air pollution settings (Lim et al., 2012). The marked change in air
149 pollution sources and composition between the heating and non-heating seasons, and the differences
150 between urban and rural areas may all lead to different biological responses in local populations. However,
151 to date, such comparative investigations are largely lacking. A further limitation of such work is the lack
152 of accurate personal exposure estimates which are crucial in high quality health studies. This may be

153 especially true when considering household air pollution (both indoors and outdoors) from traditional
154 biomass and coal stoves which may not be easily captured by typical outdoor monitoring instruments
155 (Linn et al., 2001; Brook et al., 2002). Thus, understanding the health impact of air pollution in China
156 remains a major challenge.

157 To address these issues, the UK Natural Environment Research Council (NERC), in partnership with the
158 National Science Foundation of China (NSFC), UK Medical Research Council (MRC) and UK-China
159 Innovation Newton Fund funded a major joint research programme – Atmospheric Pollution and Human
160 Health in a Chinese Megacity (APHH-Beijing). The APHH-Beijing is an integrated research programme,
161 incorporating the capabilities and strengths of the UK and Chinese science communities which is taking
162 a multi-disciplinary approach to investigating the sources, processes and health effects of air pollution in
163 the Beijing megacity. The new scientific understanding underpins the development of interventions and
164 solutions to improve air quality and reduce health impacts.

165 This special issue “In-depth study of air pollution sources and processes within Beijing and its
166 surrounding region (APHH-Beijing)” documents the research outcomes of this APHH-Beijing
167 programme, in particular the atmospheric measurement and modelling aspects.

168 This introduction paper describes the motivation and background of the APHH-Beijing programme, and
169 presents some of the background air quality and meteorological observations, particularly during the two
170 intensive field campaigns. These campaigns form one of the core research activities within APHH-Beijing
171 integrating the different themes / projects. We do not present the key scientific results of APHH-Beijing
172 in this introduction (not an overview) paper as much of the research activity are still ongoing and
173 unpublished. Key findings will be published in the Special Issue to which this paper provides key
174 background information.

175 **2. APHH-Beijing Programme Objectives**

176 The overall aim of APHH-Beijing is to better understand the sources, atmospheric transformations and
177 health impacts of air pollutants in the Beijing megacity and to improve the capability of forecasting air
178 quality and developing cost-effective mitigation measures. Specific objectives include:

- 179 • to determine the emission fluxes of key air pollutants and to measure the contributions of different
180 sources, economic sectors and regional transport to air pollution in Beijing
- 181 • to improve understanding of the processes by which pollutants are transformed or removed
182 through transport, chemical reactions and photolysis and the rates of formation and conversion of
183 particulate matter (PM) via atmospheric reactions

- 184 • to improve understanding on how the detailed properties of PM evolve and can influence their
185 physical properties and behaviour in the atmosphere and elucidate the mechanisms whereby those
186 properties may interact and feedback on urban scale and regional meteorology
- 187 • to exploit new satellite observations and regional models to place the *in-situ* campaigns into a
188 wider context
- 189 • to determine the exposure of Beijing inhabitants to key health related pollutants using personal
190 air pollution monitors and assess the association between air pollution exposure and key
191 cardiopulmonary measures
- 192 • to determine the contribution of specific activities, environments and pollution sources to the
193 personal exposure of the Beijing population to air pollutants
- 194 • to enhance our understanding of the health effects in susceptible individuals over time periods
195 when there are large fluctuations in pollutants compared with normal controls, and to identify
196 health outcomes of air pollution
- 197 • to estimate economic loss due to both physical and mental impacts of air pollution and examine
198 how Beijing can improve its air quality more cost effectively

199

200 **3. Research Themes and Integration within the APHH-Beijing Programme**

201 The APHH-Beijing programme has four themes to address the specific objectives outlined in Section 2,
202 and is delivered through five inter-related research projects:

- 203 - Theme 1 - Sources and emissions: delivered by the AIRPOLL-Beijing (Source and Emissions of
204 Air Pollutants in Beijing) project;
- 205 - Theme 2 – Atmospheric processes: delivered by the AIRPRO (The integrated Study of AIR
206 Pollution PROCesses in Beijing) project;
- 207 - Theme 3 – Health effects: delivered by two projects - the AIRLESS (Effects of AIR pollution on
208 cardiopuLmonary disEaSe in urban and peri-urban reSidents in Beijing) and the APIC-ESTEE
209 (Air Pollution Impacts on Cardiopulmonary Disease in Beijing: An integrated study of Exposure
210 Science, Toxicogenomics and Environmental Epidemiology) projects;
- 211 - Theme 4: Solutions: delivered by the INHANCE (Integrated assessment of the emission-health-
212 socioeconomics nexus and air pollution mitigation solutions and interventions in Beijing) project.

213

214 **3.1 Research Themes**

215 **3.1.1 Theme 1: Sources and emissions**

216 AIRPOLL aims to quantify the emission fluxes of key air pollutants in Beijing and the contributions of
217 different sources, economic sectors and regional transport to air pollution in Beijing. The project has

218 carried out two major field observation campaigns jointly with the AIRPRO and AIRLESS projects
219 (Sections 3.1.2 and 3.1.3) during November-December 2016 and May-June 2017. The campaigns were
220 carried out at two sites - one within Beijing (at the Institute of Atmospheric Physics (IAP) meteorological
221 tower site) and the other in the local region (the rural Pinggu site – see 4.1 for site information).

222

223 During the intensive campaigns, the project measured the fluxes of particulate and gaseous air pollutants
224 from ground-level sources by sampling on the meteorological tower (325 m) at the IAP site, which are
225 being compared with emissions estimates taken from the inventory for Beijing. This was complemented
226 by top-down fluxes inferred from satellite data for nitrogen dioxide, sulphur dioxide and formaldehyde,
227 the latter indicative of VOC oxidation processes (Palmer et al., 2003; Fu et al., 2007). Through these
228 means, the emissions inventory is being tested, allowing revisions which are being incorporated into the
229 atmospheric modelling work.

230

231 AIRPOLL also made very detailed on-line and off-line measurements of airborne particles. This included
232 continuous measurements of size distributions from 1 nm to >10 μm diameter. Large molecules and
233 molecular clusters were also measured by high resolution mass spectrometry, with a view to better
234 understanding atmospheric nucleation processes. The project has monitored the chemical composition of
235 particles in real time by Aerosol Mass Spectrometry and analysed the time-integrated particle samples
236 off-line for major and minor constituents, including organic molecular markers. AIRPOLL determined
237 the carbon-14 in water soluble organic carbon, water insoluble organic carbon and elemental carbon in
238 selected time-integrated particle samples with an aim to differentiate fossil and non-fossil particulate
239 carbon. These data are being brought together for use in receptor modelling of PM sources, which are
240 compared with other estimates of source contributions to PM concentrations. Measured ground-level
241 concentrations both from our campaign sites and the Beijing monitoring network, together with vertical
242 gradient observations at the tower and source apportionment results are compared with the predictions of
243 a chemistry-transport model and used to provide a clear distinction between advected regional pollution
244 and the impact of local sources. Divergences between measured and modelled pollutant concentrations
245 will be used to provide critical evaluation of emissions inventories, which will be enhanced iteratively
246 with a view to improving knowledge of the sources and emissions of pollutants affecting air quality in
247 Beijing.

248

249 During the campaigns, AIRPOLL and AIRLESS measured the concentrations of key tracers and reactive
250 species indicative of sources and chemical pathways at the ground-level sites, which complements
251 AIRPOLL observations.

252

253 **3.1.2 Theme 2: Atmospheric processes**

254 AIRPRO aims to study the fundamental chemical and physical processes controlling gas and particle
255 pollution, localised meteorological dynamics, and the links between them within Beijing's atmosphere.
256 Central to the project were the intensive *in situ* measurements at the IAP meteorological tower (325 m)
257 site, jointly carried out with the AIRPOLL project. AIRPRO made comprehensive and detailed local
258 observations of both primary emitted chemicals and particles, radical intermediates and secondary
259 products, for periods of contrasting local and regional emissions, solar insolation and air temperature.
260 These data allow the performance of local and regional models of air pollution to be robustly tested, both
261 for final regulated pollutant outcomes and at a more mechanistic level.

262 Observations made with instruments from multiple Chinese and UK research groups included
263 complementary measurements of key precursor trace gases such as NO_x, HONO, SO₂, CO, O₃, VOCs
264 and SVOCs, gas phase radicals such as OH, HO₂, RO₂, and NO₃, and PM including chemical (both on-
265 line and offline analyses), biological, physical and optical properties. Through multiple co-located surface
266 measurements, there was both instrumental redundancy (e.g. for equipment failures) and capacity to
267 evaluate through inter-comparison some hard-to-measure atmospheric free radicals and gases such as OH,
268 HO₂, N₂O₅, HCHO and other oxygenated VOCs. The project determined the local *in situ* chemical
269 processing of air pollution in the contrasting winter/summertime periods alongside overall atmospheric
270 reactivity, both day and at night, through a combination of modelling and proxy measurements such as
271 measured ozone production efficiency and OH reactivity.

272 The IAP tower allowed vertical profiles of key pollutants up to 320 m to be obtained and, with additional
273 remote sensing of composition and meteorology, provided insight into boundary layer stability and
274 evolution over the diurnal cycle. Quantification of shallow mixed layers proved to be vital for explaining
275 local surface *in situ* chemical processing and also street level concentrations of relevance to exposure.
276 The potentially significant vertical gradients anticipated in some chemicals and PM properties were
277 further quantified using instruments installed on the tall tower and via profiling gondola measurements.
278 The combined datasets, surface and profiles, provide the basis for evaluation of model performance, and
279 notably comparisons for those intermediates that provide indicators of whether secondary pollution
280 production is being correctly simulated.

281 **3.1.3 Theme 3: Health effects**

282 Health effects of air pollution are studied by two projects – AIRLESS and APIC-ESTEE. AIRLESS aims
283 to advance air quality and health research in Beijing by bringing together two fields of research that have
284 made rapid advancements in recent years: measurements of a wide range of pulmonary and cardiovascular
285 biomarkers in a panel study and personal monitoring of multiple air pollutants with high spatio-temporal
286 resolution by sensor technology. AIRLESS is also benefiting from the use of an extensive range of

287 pollution metrics and source apportionment results from the AIRPOLL and AIRPRO projects. These
288 data are being compared with our personal air quality assessments and used to further understanding of
289 the nature of the air pollution exposures of residents and how this relates to their health status.

290 APIC-ESTEE aims to evaluate the impacts of air pollution on cardiopulmonary health through an
291 integrated study of exposure, epidemiology, and toxicology/toxicogenomics. APIC-ESTEE has
292 investigated the relationship between ambient air pollution and personal exposures. This is being used to
293 estimate personal exposures for epidemiological analyses of long term health impacts in a cohort study
294 and of short-term effects (i.e. biomarkers, blood pressure, heart rhythm, and peak flow) in a panel study.
295 APIC-ESTEE also studied the real-world exposure-reduction and health benefit potential of face-masks,
296 a commonly used personal level intervention seen in Beijing. Furthermore, to complement the human
297 based studies into mechanisms of action, APIC-ESTEE has conducted *in vivo* analyses of mechanistic
298 effects and early life toxicogenomics/metabonomics.

299 **3.1.4 Theme 4: Solutions**

300 INHANCE aims to quantitatively evaluate the performance of China's current air pollution policies and
301 develop cost-effective solutions to mitigate the impact of air pollution in the Beijing megacity. INHANCE
302 considered not only the physical and mental health impacts and direct economic impact, but also the
303 cascading indirect economic losses occurred through inter-industrial and inter-regional linkages on the
304 supply side of the economy. INHANCE has established and evaluated interactive relationships among
305 exposure, vulnerability, impact on health, implications for industry and economic consequences.
306 INHANCE has compared and qualitatively assessed air quality policies between Beijing and other cities,
307 undertaken policy performance assessment modelling, utilised techno-economic inventories for anti-
308 pollution measures to conduct micro cost-benefit analysis of new policies; measured health and
309 macroeconomic costs and benefits in mitigating air pollution, and, transformed evidence generated into
310 practical emission alleviation pathways. On these bases, INHANCE will deliver recommendations
311 regarding integrated policy design and an assessment for policy cost-effectiveness.

312 **3.2 Integration Between the Themes and Novelty of the APHH-Beijing Programme**

313 The APHH-Beijing programme is highly integrated to ensure the biggest possible scientific and policy
314 impacts. One of the most significant integration activities between the different themes is the coordinated
315 joint field campaigns at an urban and a rural site in Beijing for Theme 1, 2 and 3 to fully exploit the
316 complementary measurements and expertise by different research groups, which is described in the
317 following sections. Theme 1 and 2 are closely related and in many senses inseparable. For example, our
318 knowledge of the sources and emissions is essential to interpret the processes while knowledge on the
319 atmospheric physical and chemical processes will help us to more accurately quantify the source
320 emissions, both via actual flux-based measurements and model evaluation of the emission inventories.

321 Furthermore, to ensure integration, Themes 1 and 2 co-located their rural site at Pinggu as that was
322 selected for the Theme 3 panel study.

323 Modelling of airborne concentrations of air pollutants within Themes 1 and 2 is fully integrated, primarily
324 via the UKCA (UK Chemistry and Aerosol), NAQPMS (Nested Air Quality Prediction Model System)
325 and GEOS-Chem models. The models simulate spatial and temporal variations of key air pollutants and
326 are being evaluated using the new observations of pollutant emission fluxes, updated emission inventories,
327 three-dimensional air quality low cost sensor observations, comprehensive composition and physics
328 measurements, as well as new process understandings generated from the APHH-Beijing programme.
329 Furthermore, in Themes 1 and 2, ADMS (Atmospheric Dispersion Modelling System) modelling results
330 for the campaign periods facilitate the estimation of population exposure in Theme 3. Outcomes of
331 Themes 1, 2 and 3 help to provide Theme 4 with a more accurate estimate of pollution costs and to develop
332 cost-effective air pollution control measures in Beijing.

333 The third stream of integration activities involves regular APHH-Beijing programme science and
334 stakeholder engagement meetings to stimulate collaboration and knowledge transfer between different
335 themes and stakeholders. Furthermore, sharing of data was made available via a dedicated depository in
336 Centre for Environmental Data Analysis (www.ceda.ac.uk). All data in the depository will be made
337 publically available by the end of 2022.

338 Together, this interdisciplinary APHH-Beijing programme delivers key scientific values and innovation,
339 including:

- 340 (1) Validation of the bottom-up emission inventories by using novel eddy covariance emission flux
341 observations from the IAP meteorological tower, integrated with satellite retrievals and numerical
342 modelling,
- 343 (2) Improvement in understanding of air pollution processes through comprehensive observations of
344 atmospheric gaseous and aerosol species integrated with atmospheric physics measurements, and
- 345 (3) Identification of the sources of air pollution that cause largest adverse human health effects by
346 carrying out novel cardiovascular health indicator measurements, integrated with personal exposure,
347 fixed station source apportionment studies and high resolution air quality modelling.

348

349 **4. Overview of the Joint Field Campaigns**

350 The two intensive campaigns took place from 10th November to 10th December 2016 and 20th May to 22nd
351 June 2017. The campaigns were carried out at both urban and rural sites.

352

353 **4.1 Site Information**

354 The winter campaign had two main sites. The urban site (39.97N, 116.38 E) is located in the Tower
355 Section of the Institute of Atmospheric Physics (IAP), Chinese Academy of Sciences where the 325 m
356 meteorological tower is located. The site, between the fourth and third North ring roads of Beijing (Figure
357 1), is in a residential area. Typical of central Beijing, there are various roads nearby. To the south, north
358 and west there are roads about 150 m away. On site there are 2 to 3 floor buildings to the south, and the
359 east and west of the tower surrounded by small trees and grass. There is a canal right to the north of the
360 site. Further to the west is a park covered mainly by conifer pine trees (Yuan Dynasty Wall Heritage
361 Park).

362

363 The rural Pinggu site in Xibaidian village (40.17N, 117.05 E) in north-eastern Beijing, was collocated
364 with the AIRLESS project cohort. Xibaidian village is about 4 km northwest of Pinggu town centre, and
365 about 60 km from IAP. There are several similar small villages nearby. The monitoring station and the
366 clinic used an unoccupied house at the north end of the village away from significant local combustion
367 sources. A two-lane road is about 300 m north of the site. With no centralised heating infrastructure
368 available, residents mainly use coal and biomass for heating and cooking in individual homes.

369

370 In the summer, an additional site was operated in Gucheng (39.2N 115.7E), Dingxing County, Hebei
371 Province. This site, about 120 km to the southwest of central Beijing, is on one of the main high pollutant
372 transport pathways from Hebei province to Beijing from the southwest. The site is in a meteorological
373 observatory surrounded by farm fields. The nearest town is about 10 km to the northeast. The nearest road
374 is 500 m to the north and the nearest village ~1 km to the west. Several villages are located around the
375 site.

376

377 In addition to the two highly instrumented urban (IAP) and rural (Pinggu) sites, 21 SNAQ (Sensor
378 Network for Air Quality) boxes, which measure CO, NO, NO₂, CO₂, O_x, size resolved particulates (0.38-
379 17.4 μm), temperature, relative humidity, wind speed and direction (Popoola et al., 2018), were deployed
380 during the summer and winter campaigns across the urban and rural areas of Beijing to map air pollutant
381 variations (red tags, Figure 1). Six additional SNAQ boxes were deployed at six different heights (8, 32,
382 102, 160, 260, and 320 m) on the IAP tower from 9-23 November 2016 and 25 January-31 December
383 2017.

384

385 Figure 1 also shows the location of the 12 national air quality monitoring stations. Hourly data for criteria
386 air pollutants (PM_{2.5}, PM₁₀, SO₂, NO₂, CO and O₃) from January 2013 to December 2017 from the stations
387 were also obtained from official sources. The closest air quality station to the urban IAP site is about 3
388 km away at the Olympic Park (G11, Figure 1).

389

390 **4.2 Instrumentation**

391 **4.2.1 Urban site**

392 Table 1 lists all instruments deployed during the campaigns at the IAP site. Most instruments ran during
393 both campaigns. A majority of the instruments were situated in the nine containers, which were at ground
394 level on the campus grass. A number of online instruments and high volume PM samplers were also
395 deployed at different heights on the meteorological tower. Vertical profile measurements of atmospheric
396 species including HONO were made during pollution events using baskets attached to the tower.
397 Additional online measurements and offline PM samplers were deployed at ground-level, on the roof of
398 a two storey building to the west (WB) and in a third-floor laboratory at the south end of the campus. In
399 addition, high-, medium- and low-volume PM samplers were placed on the roof of WB for offline
400 characterization and source apportionment.

401 **4.2.2 Rural sites**

402 At Pinggu, online instruments (Table 2) were run within an air-conditioned room on the ground floor with
403 inlets on top of the building. High-, medium- and low-volume PM samplers were deployed on a newly
404 modified flat-roof of the single storey building.

405

406 At Gucheng (summer only), a high volume Digital sampler and a single particle sampler were set up on
407 a deserted basketball court. An Aethalometer AE33 was located on top of a container at the edge of the
408 basketball court. CO and O₃ were also measured in a nearby container.

409

410 **4.3 Synoptic Scale Meteorology During the Field Campaigns**

411 Synoptic circulation patterns (e.g., horizontal advection and wet deposition) play a key role in the
412 variations of air quality in Beijing (Miao et al., 2017; Wu et al., 2017; Zhang et al., 2012). To provide the
413 synoptic context of the APHH-Beijing observations, the daily mesoscale flow patterns have been
414 classified and put into context using a 30-year climatology (Section 5.4).

415

416 Circulation types (CT) are classified using the software produced by the COST Action 733
417 “Harmonisation and Applications of Weather Type Classifications for European regions” (Philipp et al.,
418 2010) with (ECMWF Re-Analysis) ERA-Interim 6-h 925 hPa geopotential reanalysis data (Dee et al.,
419 2011) at its native 0.75° spatial resolution for the domain of interest (103-129° E, 31 - 49° N) centred on
420 Beijing (40° N, 116.5° E) covering the period 1988-2017. ERA-Interim 10 m U and V wind components
421 are used to facilitate the interpretation of the flow patterns. Of the COST733 methods (Huth et al., 2008;
422 Philipp et al., 2010, 2016; Tveito and Huth, 2016) two are used: T-Mode PCA (Principal Component
423 Analysis) and SANDRA (Simulated Annealing And Diversified RAndomization clustering). The former

424 have been used in Beijing previously (e.g. Miao et al., 2017; Zhang et al., 2012). The latter is considered
425 to perform well in clustering pressure fields and discriminating environmental variables (e.g. Demuzere
426 et al., 2011; Philipp et al., 2016). Classification is performed with the number of CTs ranging from 7 to
427 18. 11 CTs from the SANDRA method are selected (Figure 2; Table 3) to adequately represent the general
428 flow conditions around Beijing during the 30 y climatology period (Beck and Philipp, 2010).

429
430 As expected, the CTs that occurred during the two field campaign periods are different (Figure 3). During
431 the winter field campaign, the most frequent circulation type was CT 11 (24 % of the 6 h periods) which
432 was often preceded by a period of CT 9 (total 13%). Circulation types 9-11 are associated with air masses
433 that may stagnate over the Beijing urban area (Figure 2). CT 1 (accounting for 12% of the time) and CT
434 2 (17 %) are associated with the Asian winter monsoon which brings cold and dry air masses to eastern
435 China. North-westerly flow (over Beijing) is driven by high pressure in the west of the domain (Figure
436 2), which are followed by CTs 5, 3 and 7 occurred 14, 7, and 5% of the time, respectively. CTs 3 and 5
437 are associated with relatively low pressure in the northeast (Sep-May period) while CT 7 has a south-
438 easterly winds from the Bohai Sea. CTs 4, 6 and 8 did not or hardly occur during the winter campaign.

439 During the summer campaign (Figure 3b), the most frequent CTs were 8, 7, 4, and 6 (23, 25, 19, and 10
440 % of the time, respectively). CTs 8 and 6, which did not occur during the winter campaign period, are
441 associated with the summer monsoon advecting moist, warm air from the South and Southeast (Figure
442 2). While southerly and northerly flows converge over Beijing for CT 6, slightly weaker low pressure to
443 the Northeast means North-westerly flow dominates for CT 4. High pressure to the West or South of
444 Beijing is rare during the summer campaign so that CTs 1, 2, 9, and 11 do not occur and CTs 3 and 5 are
445 rather rare (6 and 1%, respectively).

446 **4.4 Meteorological Conditions During the Field Campaigns**

447 To assess how local-scale flow related to ERA-Interim fields (Section 4.3) compared to local conditions,
448 the link between the coarse gridded data and tower-based sonic anemometer observations are explored
449 based on wind roses (Figure 4). The 30 y climatology (Figure 4a, d) confirms the clear seasonality in
450 wind direction affecting the occurrence of CTs discussed (Sect. 4.3), i.e. during winter intensive campaign
451 period (10 November – 10 December) north-easterly flow clearly dominates while southerly wind
452 directions are most common during the summer campaign period (20 May – 22 June). The wind roses for
453 winter 2016 and summer 2017 (Figure 4b, e) are slightly noisier, but show similar tendencies as the
454 climatology. The general large-scale patterns are consistent with the in-situ wind measurements (Figure
455 4c, f). However, a slight diversion towards northerly and south-westerly flow and lower wind speeds
456 occurred in winter and summer (Figures 4c and f), respectively, when compared to the larger scale data
457 (Figures 4b and d). In addition, south-westerly flows were more frequent in winter 2016 (Figures 4b and

458 c) than during the 30 year average climatology (Figure 4a), which had the potential to bring more polluted
459 air in the upwind Hebei province to the observation sites in Beijing.

460

461 At 102 m, the flow is consistent with northerlies and north-westerlies in the winter campaign and
462 dominantly southerly and easterlies during the summer campaign (Figure S1). The measured hourly mean
463 wind speed, temperature and relative humidity were 3.1 m s^{-1} , $8.3 \text{ }^\circ\text{C}$ and 43.8% in winter, and 3.6 m s ,
464 $25 \text{ }^\circ\text{C}$ and 46.7% in summer, respectively. Typical diurnal patterns were observed with higher wind speed
465 and temperature during the day and RH at night. During the winter haze events (defined in Figure 5) wind
466 speed at 102 m were low (an average of 1.8 m s^{-1}) and mainly from the south-west direction (Figure S1).

467

468 **5. Air Quality During the Field Campaigns**

469 **5.1 Winter**

470 During the winter campaign, the daily average concentration of $\text{PM}_{2.5}$ at IAP was $91.2 \text{ } \mu\text{g m}^{-3}$ from the
471 Partisol gravimetric measurements (Table 4) and $94.0 \text{ } \mu\text{g m}^{-3}$ from an online FDMS (Filter dynamic
472 measurement system). The maximum hourly $\text{PM}_{2.5}$ concentration was $438 \text{ } \mu\text{g m}^{-3}$ (Figure 5 which shows
473 the haze events listed in Table 5). $\text{PM}_{2.5}$ concentrations significantly exceeded both the daily air quality
474 limit of China ($75 \text{ } \mu\text{g m}^{-3}$) and WHO ($25 \text{ } \mu\text{g m}^{-3}$). During the whole winter campaign period, nearly 50%
475 of the hours had $\text{PM}_{2.5}$ mass concentration higher than $75 \text{ } \mu\text{g m}^{-3}$ (Figure 5). The online PM_{10}
476 concentration observed at the Olympic Park national air quality monitoring station was up to $560 \text{ } \mu\text{g m}^{-3}$
477 during the campaign with an average of $130.6 \text{ } \mu\text{g m}^{-3}$. Average concentrations of NO_2 , O_3 , SO_2 and CO
478 were 69.7 ± 33.3 , 16.4 ± 17.0 and $14.9 \pm 11.1 \text{ } \mu\text{g m}^{-3}$ and $1.53 \pm 1.02 \text{ mg m}^{-3}$, respectively (Table 4).
479 Most of the criteria pollutants showed a similar temporal pattern (Figure 5), except O_3 .

480

481 The daily average concentration of $\text{PM}_{2.5}$ was $99.7 \text{ } \mu\text{g m}^{-3}$ at Pinggu (Table 4; based on Partisol
482 gravimetric measurements). The maximum hourly $\text{PM}_{2.5}$ concentration was $617 \text{ } \mu\text{g m}^{-3}$ (Figure 5). Similar
483 to that at IAP, nearly 50% of the hours had $\text{PM}_{2.5}$ mass concentrations greater than $75 \text{ } \mu\text{g m}^{-3}$. Average
484 concentrations of NO_2 , O_3 , SO_2 and CO are 46.4 ± 25.5 , 22.3 ± 22.2 , and $15.4 \pm 6.7 \text{ } \mu\text{g m}^{-3}$, and $1.47 \pm$
485 1.17 mg m^{-3} respectively (Table 4). $\text{PM}_{2.5}$ was slightly higher at the rural site but NO , CO and SO_2 were
486 comparable between the two sites. $\text{PM}_{2.5}$ and O_3 each had similar temporal patterns at the urban and rural
487 sites (Figure 5), indicating a synoptic scale meteorological impact. The larger difference in the temporal
488 variation of NO , NO_2 and SO_2 may reflect the varying contribution of more local sources. Large
489 differences in temporal patterns of air pollutants were found on 4 December 2016 when $\text{PM}_{2.5}$, SO_2 and
490 NO concentrations were much higher at Pinggu than at IAP.

491 Diurnal cycles of particles, NO₂ and CO showed no distinct peak but an increment during the nighttime,
492 suggesting the possible impact of boundary layer and/or anthropogenic emissions in winter (Figure 6).
493 The peak NO levels at 7 am are likely caused by the morning rush hour road traffic. PM_{2.5} concentration
494 increased sharply from 6 pm at Pinggu (not shown), suggesting important local emissions, likely domestic
495 heating and cooking. SO₂ and O₃ had their highest levels in mid-morning or at noon (Figure 6).

496 Variations of particles, NO_x and SO₂ show that higher levels of these pollutants when air masses were
497 from the south or southwest (Figure S2), indicating it was impacted by regional transport. All pollutants,
498 except O₃, had higher mass concentrations when wind speeds were low, suggesting an influence from the
499 local sources. The NO wind rose suggests a strong local source with little contribution from long-range
500 transport. The O₃ concentration was higher during northerlies and when the concentrations of other
501 pollutants such as NO_x and PM_{2.5} were lower (Figure S2).

502 SNAQ box measurements at six levels (8 to 320 m) during the winter campaign (Figure 7) have similar
503 overall temporal patterns of CO and NO to that measured by standard gas analyser (Figure 5). In most
504 cases, the air pollutant levels are similar at different levels of the tower. There are notable differences in
505 NO, CO and CO₂ on 11, 12 and 16 / 17 November, which suggests that the mixed layer height was low
506 (e.g., <150 m). Interestingly, the O_x (NO₂ + O₃) levels are relatively homogeneous across the different
507 levels. These measurements have implications on the role atmospheric chemistry play in transformation
508 of species in the boundary layer, and the measurements also provide useful information that confirm
509 mixed layer height determinations from independent methods such as the ceilometer (Table 1).

510 According to the meteorological standards (QX/T113-2010), haze is defined as: i) visibility < 10 km at
511 relative humidity (RH) <80%; or ii) if RH is between 80 and 95%, visibility < 10 km and PM_{2.5} > 75 µg
512 m⁻³. During the winter campaign 640 of the 1633 h were classified as haze periods using visibility data
513 from Beijing Capital Airport (Figure S3); within the haze hours, 75% had PM_{2.5} greater than 75 µg m⁻³
514 (Area A, Figure S3) and the rest had a visibility less than 10 km but with a RH <80% (Area B, Figure S3).

515 Characteristics of five major haze events during the winter campaign (Figure 5) show that PM_{2.5}, NO₂,
516 SO₂ and CO had similar trends but O₃ levels dropped to very low concentration (<2 ppb). The events are
517 defined in Table 5.

518 **5.2 Summer**

519 Concentrations of air pollutants excluding ozone during the summer campaign were much lower than in
520 winter (Figure 8, Table 4). Average daily concentration of PM_{2.5} and PM₁₀ at IAP were 31.4 ± 14.7 and
521 74.9 ± 29.3 µg m⁻³ (based on gravimetric method), respectively. These levels were slightly higher than at
522 Pinggu (27.8 ± 13.3 and 62.9 ± 29.3 µg m⁻³). Concentrations of ozone were four to five times higher
523 during the summer campaigns (106.9 ± 71.6 µg m⁻³ at IAP, and 91.8 ± 62.7 µg m⁻³ at Pinggu) than in the

524 winter campaign. Average concentration of NO₂, SO₂ and CO were 41.3 ± 23.5 and 6.3 ± 6.8 μg m⁻³ and
525 0.61 ± 0.32 mg m⁻³ at IAP respectively (Table 4). The concentrations of NO₂ and CO were lower at Pinggu
526 while that of SO₂ was similar. All pollutants except PM_{2.5} show more or less different temporal patterns
527 (Figure 8), suggesting differences in sources at Pinggu and IAP during the summer campaign.

528 Diurnal patterns of NO, NO₂, and CO at IAP showed a distinct peak in the early morning, suggesting the
529 contribution of traffic emissions (Figure 6). O₃ and O_x concentration peaked in mid-afternoon. The IAP
530 PM_{2.5} pollution rose suggests that both local and regional sources (from the south and south-east direction)
531 impact the site (Figure S2). Unlike winter, high ozone concentrations occur during southerlies to
532 southwesterlies, suggesting a regional source of this pollutant. NO and NO_x were largely from local
533 sources during the summer campaign.

534 Characteristics of two minor haze events (IAP) during the summer campaign (Figure 8) are shown in
535 Table 5.

536

537 **5.3 Air quality in the Wider Beijing Megacity During the Field Campaigns**

538 To assess if the IAP air quality is broadly representative of the wider Beijing megacity, variables were
539 correlated with the 12 national air quality station data (Figure 9). A high correlation is observed with
540 PM_{2.5} across all sites except the rural background air quality station at Ming Tombs (G2, Figure 1); PM₁₀,
541 CO and NO₂ at the urban sites are highly correlated but not with the rural and suburban sites (G2, G9 and
542 G10, Figure 1) suggesting a more local source for these pollutants, comparing to PM_{2.5} and O₃; SO₂
543 between sites shows a lower correlation compared to all other pollutants. The particularly high spatial
544 correlations of both PM_{2.5} and O₃ across almost all sites indicates a regional pollution phenomenon for
545 the two pollutants. These results suggest that the air quality at the IAP urban site was broadly consistent
546 with that at the other urban sites.

547

548 In general, PM_{2.5} mass concentrations are similar at all the urban sites including IAP which are higher
549 than at the suburban and rural background national monitoring sites (G2, G9 and G10, Figure S4). The
550 Pinggu site has relatively high PM_{2.5} pollution during the winter campaign but has the lowest
551 concentrations during the summer campaign. This suggests that local anthropogenic sources have a major
552 impact on PM_{2.5} at this site during the winter campaign. Source apportionment results, notably high time
553 resolution data are being used to explore this.

554

555 The PM_{2.5} concentrations measured at IAP are highly correlated with those at the nearly national air
556 quality station (Olympic Park, or Aotizhongxin, see Figure 1) (Figure S5), which gives confidence that

557 national air quality stations are of sufficient quality to provide valuable information on the spatial and
558 temporal variation of key pollutants to supplement campaign measurements.

559

560 Table 4 shows that the IAP concentration data for all air quality variables are very close to the five year
561 mean of the 12 national air quality monitoring stations. This lends further confidence that the chosen
562 urban site represented well the overall pollution in the Beijing urban area.

563

564 **5.4 Synoptic Circulation and Air Quality**

565 The average mixed layer height observed at IAP varies with season and CT type (Figure 10a). Lower
566 mixed layer height is usually linked to air pollution events. The 11 CTs (Section 4.3) are clearly associated
567 with distinct air quality conditions based on analysis of hourly air quality data for 2013-2017 at one of
568 the national urban air quality stations (G11, Olympic Park, Figure 1). Relatively low wind speeds of CT
569 7 may contribute to the long haze event from 15/11/2016 to 19/11/2016 (Fig. 5). Most haze events during
570 the winter campaign are cleared out by fresh air masses being advected from the North in CTs 3 or 5
571 (Figure 3), which is also marked by the increase in wind speed observed (Figure S1). Relatively lower
572 PM_{2.5} concentrations occurred (Figure 10b) under NE flow conditions (CTs 1-5), and higher
573 concentrations during southerly flow (CTs 6-8, 10). The highest PM_{2.5} concentrations occur during the
574 heating season when regional flow showed stagnation (CT 9, 11). All haze events during the winter
575 campaign (Figures 3&5) are dominated by those CTs although CTs with NE flow conditions occurred for
576 short periods within the haze events (e.g. 18/11/2016, 04/12/2-16). Ozone levels are highest during CTs
577 5-8 (Figure **Error! Reference source not found.**10c), which predominate during spring and summer
578 (Figure 10d).

579

580 In the Oct 2016 – Sept 2017 period (Figure 10e), the relative frequency of CTs differs slightly from the
581 long-term climatology (Figure 10d). During the winter campaign, clean air advection from the NE (CTs
582 1-3) was less frequent than in the 30-y climatology. Given synoptic circulation types associated with
583 stagnation do have a similar occurrence during the winter campaign compared to the same time period
584 within the previous five years (with CT 9 8% less frequent and CTs 10 and 11 2% and 10% more frequent;
585 Figure 10f), PM_{2.5} concentrations were similar to the 5 year mean (Figure 10g, winter campaign period
586 compared to the same dates during 2013-2017). During the summer campaign, south-north contrasts in
587 geopotential were apparently reduced so CT 6 was 12% less frequent, while CT 7 was 11% more frequent
588 (Figure 10f). The reduced advection of particles from southerly directions might have contributed to a
589 33% lower PM_{2.5} concentrations compared to the five year average for the same time of year (Figure 10g).
590 The relative decrease in O₃ (Figure 10g) during the winter campaign (24%) might be explained by cloud
591 cover differences, which is being investigated.

592 **5.5 Summary of Air Quality during the Campaigns**

593 In summary, the winter campaign was characterised by several high PM_{2.5} pollution events with peak
594 hourly concentrations at the urban site ranging up to 617 $\mu\text{g m}^{-3}$ (at Pinggu) whereas the summer
595 experienced events of high ozone concentrations with the highest hourly average of 335 $\mu\text{g m}^{-3}$ (at IAP)
596 Air quality was generally poor during the winter campaign with an average PM_{2.5} concentration of 91 μg
597 m^{-3} in urban Beijing, but less severe than in the same period in 2015. Synoptic scale meteorological
598 analysis suggests that the greater stagnation and weak southerly circulation in November/December 2016
599 contributed to the poor air quality during all haze events detected, and overall the PM_{2.5} pollution level
600 was similar to the five year average (2013-2017). PM_{2.5} levels were relatively low during the summer
601 campaign with the highest daily concentration of only 79 $\mu\text{g m}^{-3}$, matching the cleanest periods over the
602 previous five years.

603

604 **6. Preliminary Air Quality Modelling and Pollution Climatology of the Campaign Periods**

605 Air quality modelling is a key component of the APHH-Beijing programme. A range of models have
606 been applied that span global (UKCA, GEOS-Chem), regional (WRF-Chem, CMAQ, NAQPMS) and
607 urban to street scales (ADMS). This section provides an example of the comparison between model
608 simulated pollutant concentrations and APHH-Beijing observations made at IAP to demonstrate model
609 capabilities. Results from specific modelling studies will be published separately.

610

611 Figure 11 shows that the magnitude and variation of wintertime PM_{2.5} concentrations are reasonably
612 reproduced by NAQPMS during the winter campaign, although there are some weakness in capturing
613 the highest PM_{2.5} levels during the haze events at the end of November and start of December. This is
614 partly due to the representation of local meteorological features during this period, which bring these
615 episodes to an end 6-12 hours early. The diurnal variations in O₃ during the summertime are reproduced
616 relatively well by UKCA, which captures the rapid daytime formation of O₃ and strong nighttime
617 removal. The very highest levels of daytime O₃ are underestimated with the model, particularly during
618 the episode at the end of May. However, there is a strong local contribution to this as evident from the
619 lower concentrations measured at Pinggu (Figure 8), and these local differences are not fully resolved
620 with the model. Despite this, the day-on-day build-up of daytime O₃ during the periods of 22-27 May
621 and 11-16 June is captured, and demonstrates that the model reproduces the synoptic drivers of local O₃
622 formation well.

623

624 We also investigated how representative the campaign periods were of the selected seasons in Beijing by
625 comparing pollutant levels with those from the same period each year over the 2013-2017 period. The

626 NAQPMS model was run for the full 5-year period driven by NCEP meteorology and using temporally
627 varying emissions for a single year that is broadly representative of 2013 conditions. The same emissions
628 were used each year so that the meteorological contribution to pollutant levels could be assessed. This
629 provides important information that cannot be obtained from the monitoring data (as emission varies year
630 by year). The frequency distribution of PM_{2.5} over each campaign period for each year is shown in Figure
631 12. Winter 2016 was broadly typical of the 5-year period, with similar characteristics to winter 2014, but
632 both years show higher PM_{2.5} under the same emissions than in 2013 or 2017. In addition, winter 2015
633 had substantially less favourable conditions for air quality, and more stagnant conditions led to three
634 extended pollution episodes over the period with PM_{2.5} exceeding 200 µg m⁻³. In contrast, the summer
635 period in 2017 was cleaner than average, with PM_{2.5} levels very similar to 2015, and about 25% less than
636 in 2013, 2014 or 2016. These results are broadly consistent with those based on synoptic weather analyses
637 (section 5.4) as well as by Vu et al. (2019).

638 7. Summary

639 APHH-Beijing is an integrated and multidisciplinary research programme conducted by leading UK and
640 Chinese researchers to (1) quantify sources and emissions of urban atmospheric pollutants; (2) elucidate
641 processes affecting urban atmospheric pollution events; (3) estimate the personal exposure and impacts
642 of air pollution on human health, and (4) develop intervention strategies to improve air quality and reduce
643 health impacts in the Beijing megacity. This introduction paper outlines the motivation of the APHH-
644 Beijing programme as well as providing the background air quality and meteorological conditions during
645 the two intensive field campaigns that form the basis of data interpretation for campaign observations.

646 APHH-Beijing has measured the fluxes of key air pollutants, including NO_x, CO, BC, VOCs and
647 speciated particulate matter, applied a suite of traditional and modern techniques to apportion the sources
648 of particulate matter, determined a wide range of pulmonary and cardiovascular biomarkers linking to
649 direct personal exposure and extensive fixed-station monitoring as well as source apportionment results,
650 and has evaluated the effectiveness of Beijing's air pollution control policies using both chemical
651 transport models and novel machine learning techniques. A number of papers have already been published
652 by the APHH-Beijing programme including those in this special issue (Wang et al., 2019; Pan et al., 2019;
653 Xia et al., 2018; Zhou et al., 2018; Wang et al., 2018b; Lyu et al., 2019; Hollaway et al., 2019; Du et al.,
654 2018; Liu et al., 2018a,b; Smith et al., 2019; Vu et al., 2019; El zein et al., 2019). More papers are being
655 prepared for publication in this special issue and elsewhere, which will cover (but are not limited to)
656 emission fluxes of air pollutants, chemical composition and source apportionment of fine particles,
657 satellite observations of trace gases and aerosols, sources and processes leading to haze events and
658 photochemical smogs, physical and optical properties of aerosol particles, formation processes of
659 secondary aerosols, urban meteorology, feedbacks between haze, photochemistry and meteorology,

660 integrated regional and urban scale modelling, personal exposure to air pollutants and human health
661 effects of air pollution.

665 **ACKNOWLEDGEMENT**

666 Funding is provided by UK Natural Environment Research Council, Medical Research Council and
667 Natural Science Foundation of China under the framework of Newton Innovation Fund (NE/N007190/1
668 (R Harrison, Z Shi, W Bloss); NE/N007077/1 (W Bloss)); NE/N00700X/1 (S Grimmond),
669 NE/N007018/1 (F Kelly); NSFC Grant 81571130100(T Zhu), NE/N007115/1 (A C Lewis, A R Rickard,
670 D C Carslaw); NE/N006917/1 (J D Lee, J F Hamilton, R E Dunmore); NE/N007123/1 (J Allan, C
671 Percival, G McFiggans, H Coe); NE/N00695X/1 (C Percival, H Coe, G McFiggans, J Allan);
672 NE/N006976/1 (N Hewitt, O Wild); NE/N006925/1 (O Wild); NE/N006895/1 (D Heard, L Whalley);
673 NE/N00714X/1 (D Guan), NE/N007182/1 (M Loh); NSFC 41571130024 (P Fu) and NE/N006879/1 (P
674 Palmer). Other Grant supports from Newton Fund/Met Office CSSP-China (S Grimmond; R Doherty and
675 Z Shi), Royal Society Challenge Grant (CHG/R1/17003, Palmer) and NERC (NE/R005281/1, Shi) are
676 acknowledged. Field help from Hong Ren, Qiaorong Xie, Wanyu Zhao, Linjie Li, Ping Li, and Shengjie
677 Hou from IAP, Kjell zum Berge, Ting Sun at Reading University, Wu Chen, Yanwen Wang, Yunfei Fan,
678 Teng Wang, Xi Che, Tao Xue, Pengfei Liang, Yingruo Li, Xinyan Hu, and Xinghua Qiu from Peking
679 University, Li Yan, Hanbin Zhang, Yutong Cai, and Bingling Zhou from King's College London, Anika
680 Krause from Cambridge University are also acknowledged. Many other staff and students from different
681 institutions also contributed to the field campaigns and programme.

682 **AUTHOR CONTRIBUTIONS**

683 ZS drafted the manuscript and is the science coordinator of the APHH-Beijing programme. RMH, KBH,
684 ACL, PQF, TZ, FJK, ML, ZWS, DBG and ST are lead PIs of the five research projects who led the
685 funding applications and the research. They also drafted Section 2. TV plotted many of graphs and carried
686 out the data analysis. SK, SG and MD carried out analysis and wrote Section 4.3 and 5.4; and YLW, MH,
687 ZFW and OW carried out modelling and plotted Figure 11 and 12. PFQ, JL and ZT led the air quality
688 measurements at the two measurements sites. SY, JL, RED, LR, DL, JA, DB, WJ, LC, LC, HC, TD, FKD,
689 BZG, JFH, MH, DH, CNH, MH, DSJ, XJJ, RJ, MK, LK, BL, LC, JL, WJL, KDL, GM, MM, GM (Mills),
690 JA, XFW, EN, BO, CP, PIP, OP, CR, CY, FL, JG, JC, LYS, YS, SRT, QQW, WHQ, XMW, ZFW, LW,
691 XFW, ZJW, PHX, FMY, QZ, YLZ and MZ contribute to the field observations, laboratory measurements
692 and / or modelling. ZS, SG, RMH., ZT, JL, OW, JA, JB, WJB, DC, DCC, HC, TD, RD, FKD, PQF, MFG,
693 DBG, JFH, KBH, MH, DH, CNH, MH, XJJ, RJ, MK, FJK, LK, ACL, JL, ML, KL, GM (Mann), GM

694 (McFiggans), MM, PM, EN, FO, PIP, CP, CR, ARR, LYS, GYS, DS (Spracklen), DS (Stevenson), YS,
695 XJW, JFL, BB, QC, ZWS, ST, SRT, XMW, ZFW, LW, ZJW, PHX, QZ, YHZ and MZ contributed to the
696 funding applications, programme meetings and relevant programme research and/or supervision.

1209

1210 **Figure 1:** Study area topography (source: googlemap) of Beijing / Tianjing / Hebei region (a) with
1211 the rectangle showing enlarged study area; locations of measurement sites (Institute of
1212 Atmospheric Physics (IAP)– urban Beijing, Pinggu – rural Beijing; and Gucheng –
1213 upwind site in Hebei province), SNAQ box sites (red symbols) and the 12 national air
1214 quality monitoring stations (G1 to G12, blue symbols) (b).. The shaded area shows the
1215 Beijing builtup area. (Source: a and b - Goggle Map topographic background imagery; c
1216 – taken by Jian Zhao from IAP). G1: Wangshouxigong; G2: Dingling (Ming
1217 Tombs); G3: Dongsì; G4: Tiantan; G5: Nongzhanguan; G6: Guanyuan; G7:
1218 Haidianquwanliu; G8: Shunyxicheng; G9: Huairouzhen; G10: Changpingzhen; G11:
1219 Aotizhongxin (Olympic Park); G12: Gucheng. Categories: Urban: G1, G3, G4, G5, G6,
1220 G7, G8, G11, G12; Suburban: G9, G10; Rural: G2.

1221

1222 **Figure 2:** ERA-Interim (1988-2017) average 925 hPa geopotential with 10 m horizontal wind

vector for 11 circulation types classified for Beijing (municipal boundary thin solid line) surroundings (103-129° E, 31 - 49° N) determined with the SANDRA method (COST733 class software). Frequency of occurrence is given in cluster caption. For discussion of conditions associated with each CT see Section 4.3.

Figure 3: Time series of circulation types (CTs) during the two field campaigns: (a) winter and (b) summer. The 11 CTs are shown in Figure 2. See text for more description. Shading shows the pollution events identified in Section 5 and Figure 5.

Figure 4: Beijing wind roses: (a, b, d, e) ERA-Interim 10 m horizontal wind (40° N, 116.5° E) and (c, f) sonic anemometer (Table 1) at IAP 320 m agl for (a) 5 November – 10 December in 1988-2017, (d) 15 May – 22 June in 1988-2017, (b, c) 5 November – 10 December 2016, and (e, f) 15 May – 22 June 2017.

Figure 5: Time-series of air quality variables at the urban and rural sites during the winter campaign; Five haze events are indicated (shading; see also Table 4).

Figure 6: Diurnal patterns of gaseous pollutants normalized by average concentrations at IAP during winter and summer campaigns. Line shows the mean concentrations and shaded area as 95% confidence interval in the difference in mean concentrations

Figure 7: Time series of CO₂, CO, NO, O_x (NO₂+O₃) and wind speed at six heights (colour) measured with SNAQ boxes on the IAP tower during the winter intensive field campaign.

Figure 8: Time-series of air quality variables at the urban and rural sites during the summer campaign. Two minor haze events are indicated (shading).

Figure 9: Correlations between the air quality at IAP, PQ and 12 monitoring station around Beijing. Stations G1-G12 (Figure 1(b)) are labelled 01-12, PG = Pinggu.

Figure 10: Analysis by circulation type (CT; Sect. 4.3) of: (a) daily maximum mixed layer height (MLH) determined from ALC observations at IAP between November 2016 – June 2017 (analysis method, Kotthaus and Grimmond, 2018b); concentration of (b) PM_{2.5} and (c) O₃ at the Olympic Park (i.e. Aotizhongxin) in 2013-2017 from the national air quality

1258 network for different CTs; occurrence of CTs in (d) 1988-2017 and (e) Oct 2016 – Sept
1259 2017; (f) anomaly of CT frequency during the campaigns compared to 5 y (2013-2017)
1260 averages; and (g) anomaly of PM_{2.5} and O₃ during the campaigns compared to 5 y (2013-
1261 2017) averages. IOP = intensive observation period (i.e., campaign period).

1262
1263 **Figure 11:** Comparison of observed (at IAP) and modelled pollutant concentrations showing (a) PM_{2.5}
1264 concentrations during the winter campaign compared with NAQPMS simulations, and
1265 (b) O₃ mixing ratios in summer compared with UKCA simulations.

1266
1267 **Figure 12:** Frequency distribution of PM_{2.5} in Beijing over the winter (top) and summer (bottom)
1268 campaign periods from the NAQPMS model compared with those from the same periods
1269 over the past five years under the same emission conditions.

1271 **Table 1:** Overview of measurements in APHH-Beijing at the urban site.
