## Diurnal variation

Since the SMEAR II station is located in a rather remote area, we did not expect to see any strong diurnal variation that could be caused by anthropogenic activities. In the article we presented the diurnal variation of  $\sigma_{\text{sca}}$ ,  $\sigma_{\text{abs}}$  and  $\omega_0$ , since they had the most clear variation. The diurnal variation of all the PM10 AOPs are presented in Fig. S1 separated by different seasons. The diurnal variation was similar to the PM1 particles, so we do not present that separately.

The clearest diurnal variation was seen for  $\sigma_{\text{abs}}$ , which had an effect on  $\omega_0$  and  $k$  that can be observed in Fig. S1. For  $n$  the diurnal variation is barely visible, but it is the opposite to  $k$ . For the size depended properties  $b$  and  $\alpha_{\text{sca}}$ , there is no daily variation whatsoever. For the  $\alpha_{\text{abs}}$ , there is no variation during the winter, but during other seasons, the  $\alpha_{\text{abs}}$  experiences a small decrease during the daytime. The variation of the  $\alpha_{\text{abs}}$  is strongest during the summer and during the other seasons the variation is rather small. In the summer, there is more organic material present that can condensate on BC particles and thus cause variation in the  $\alpha_{\text{abs}}$ .

**Figure S1: Diurnal variation of different optical properties for different seasons for PM10 particles. The solid black line represents the median value and the dashed lines are the 25<sup>th</sup> and 75<sup>th</sup> percentiles.**
