14

15 **Abstract**

16 A 180 m long (ca. 274 years) ice core was drilled in the saddle of the Aurora
17 Peak of Alaska (63.52°N; 146.54°W, elevation: 2,825 m). The ice core samples were
18 melt, concentrated and then derivatized with N,O-bis-(trimethylsilyl)
19 trifluoroacetamide with 1% trimethylsilyl chloride and pyridine followed by gas
20 chromatography/mass spectrometry analyses. Levoglucosan, dehydroabietic acid, and
21 vanillic acid are reported for the first time from the alpine glacier to better understand
22 historical biomass burning activities in the source region of southern Alaska. These
23 organic compounds showed higher concentrations with many sporadic peaks in the
24 1660s-1830s, 1913, and 2005. Moreover, there are few discrepancies of higher spikes
25 among them after the 1970s with sporadic peaks in 1994-2007 for dehydroabietic acid.
26 Historical trends of levoglucosan, dehydroabietic and vanillic acid showed that
27 biomass burning activities from resin and lignin in boreal conifer trees, other higher
28 plants and grasses were significant before the 1840s and after the 1970s in the source
29 regions of southern Alaska, being different from previous ice core studies. Long-
30 range atmospheric transport could be important for levoglucosan compared to
31 dehydroabietic acid in the North Pacific Rim (NPR). We found weak or no
32 correlations of levoglucosan with NO_2^- ($r=0.06$), NO_3^- (0.04), nss-SO_4^{2-} (0.08), nss-K^+
33 (0.11), and NH_4^+ (0.11) from the same ice core, suggesting that these anions and
34 cations do not represent a gleaming signal of biomass burning activities in the source
35 regions for southern Alaska. Hence, this study reveals a new dimension of biomass
36 burning periodic cycles in the NPR.

37

38 1. Introduction

39 Ice core records provide the long-term changes in deposition and
40 concentration of biomass burning organic (e.g., formate, acetate, dicarboxylic acid,
41 pyruvic acid and α -dicarbonyls) and inorganic (e.g., NH_3^+ , SO_4^{2-} , NO_3^- and NO_2^-)
42 atmospheric chemical species, which are reported elsewhere (Giorio et al., 2018;
43 Wolff et al., 2012; Kawamura et al., 2012; Lamarque et al., 2010; Kaufmann et al.,
44 2010; Andreae and Merlet, 2001; Legrand and Mayewski, 1997; Yang et al., 1995).
45 Biomass burning activities such as forest fires and residential heating have some
46 extent on climate change effect (Keywood et al., 2011; Whitlow et al., 1994). Many
47 studies have shown that there is some discrepancy of temporal and spatial biomass
48 burning activities (Kawamura et al., 2012; Whitlow et al., 1994; Kaplan et al., 2010
49 and references therein) in the Northern and Southern Hemisphere (NH/SH). These
50 studies found different atmospheric transport patterns from source region to sampling
51 site for different ice core records (Whitlow et al., 1994), which can alter the glacio-
52 chemical cycle in the NH and SH.

53 There are a few studies of specific organic tracers of biomass burning for an
54 ice core, such as levoglucosan (1,6-anhydro- β -D-glucopyranose), which is pyrolysis
55 product of cellulose and hemicellulose); dehydroabietic acid (1-
56 phenanthrenecarboxylic acid) and vanillic acid (4-hydroxy-3-methoxybenzoic acid);
57 and other compounds (e.g. mannosan and galactosan) in the NH (Kawamura et al.,
58 2012). Kawamura et al. (2012) first reported these specific biomass burning tracers
59 (levoglucosan, dehydroabietic and vanillic acid) for an ice core (AD 1693-1997),
60 collected from the Kamchatka Peninsula near the eastern coast of Russia (56°04'N,
61 160°28'E, Elevation: 3,903 m).

62 This paper reports three compounds in an ice core, which was collected from
63 the Aurora Peak of southern Alaska (APA), inland of the northeast Pacific Ocean. The
64 study covers 1665-2008 to better understand the historical atmospheric transport
65 variability between the western North Pacific region (Kawamura et al., 2012) and
66 eastern North Pacific region (this study) from source regions. Particularly, 10 day
67 backward trajectory from 1992-2002 showed that southern Alaska can receive air
68 masses from the North Pacific Regions, East Asia, Eastern Russia-Siberia, higher
69 latitudes of Alaskan regions, Japan, and Canadian regions in the troposphere (>300
70 hPa) (Yasunari and Yamazaki, 2009). Similarly, the Kamchatka Peninsula also can
71 receive air masses from Siberia, Far East, North China and Eastern Europe²
72 (Kawamura et al., 2012).

73 2. Materials and Methods

74 An ice core (180 m deep, 274 years old) was drilled in the saddle of the
75 Aurora Peak of southern Alaska, which is located at 63.52°N, 146.54°W, elevation:
76 2,825 m (Figure 1). This 180 m long core was divided into ~50 cm pieces and directly
77 transported to the laboratory of the Institute of Low Temperature Science (ILTS),
78 Hokkaido University, Japan and stored in a dark cold room at -20°C until analysis.
79 The ice core ages were determined by using annual counting of hydrogen isotopes
80 (δD) and Na^+ seasonal cycles (Tsushima, 2015; Tsushima et al., 2015). These ice core
81 samples were shaved off (~5 – 10 mm) on a clean bench at -15°C in a cold room. A
82 ceramic knife was used to avoid a possible adsorbed contamination during sample
83 collection using the method previously reported (Kawamura et al., 2012; Pokhrel et
84 al., 2015). These scraped samples were kept for 24 hours in a container in a standard
85 clean room and were transferred into 800 ml glass bottles. All steps are followed as
86 reported previously prior to analyses (Pokhrel et al., 2015; Pokhrel, 2016; Kawamura

87 et al., 2001). Total number of ice core sections was 147 (50 cm long, one quarter cut);
88 i.e., sampling frequency was ~40% of 180 m deep ice core.

89 These melt ice core samples (150 mL) were concentrated to almost dryness
90 using a rotary evaporator under a vacuum in a pear shape flask (300 ml) and extracted
91 by a mixture of CH₂Cl₂/CH₃OH (2:1) using an ultrasonic bath (Kawamura et al.,
92 2012). The total dissolved and particulate organic matter was further eluted with
93 CH₂Cl₂ and methanol to extract the organic compounds adsorbed on the particles as
94 reported previously (Fu et al., 2008; Simoneit et al., 2004). The extract and eluents
95 were transferred to 1.5 mL glass vials and again dried under a nitrogen stream.
96 Extracts were derivatized with 99% N, O-bis-(trimethylsilyl) trifluoroacetamide
97 (BSTFA) +1%trimethylchlorosilane (TMCS) at 70°C for two hours (Kawamura et al.,
98 2012). The derivatized fractions were further dissolved in n-hexane and determined
99 by gas chromatography/mass spectrometry (GC/MS) using a capillary column (HP-
100 5MS, 30 m × 0.32 mm I.D. × 0.25 μm film thickness) installed with a split/splitless
101 injector (Kawamura et al., 2012). Levoglucosan, dehydroabietic acid and vanillic acid
102 were determined using GC/MS by comparing the authentic standards and mass
103 spectral data of NIST/Willey library as external standards. More details are reported
104 elsewhere (Fu et al., 2008; Simoneit et al., 2004).

105 We conducted triplicate analyses for three real ice core samples to check the
106 uncertainty in the determinations of concentrations. The uncertainty (standard
107 deviation) of levoglucosan, dehydroabietic and vanillic acid were 6.72, 0.74 and
108 2.40 %, respectively. Moreover, recovery of traject compounds were better than 85%.

109 To identify the physical functioning fire smoldering spot as possible source
110 regions of biomass burning events, we prepared annual composite maps (2001 to
111 2008 AD) of the Moderate Resolution Imaging Spectroradiometer (i.e. MODIS)

112 effective hot spot from the Earth Observing System Data and Information System
113 (EOSDIS) using the Terra and Aqua satellites of NASA
114 (<https://earthdata.nasa.gov/data/near-real-time-data/forms/>).

115 3. Results and Discussion

116 Anhydromonosaccharides can lead an important fraction of water-soluble
117 organic carbon (Gao et al., 2015; Verma et al., 2015). It is produced from the
118 pyrolysis and/or combustion of cellulose and/or hemi-cellulose from wildfires and
119 domestic wood fires (Simoneit, 2002) at temperatures above 300 °C (Simoneit et al.,
120 2002; Fraser and Lakshmanan, 2000; Shafizadeh, 1984). Many studies have shown
121 that levoglucosan ($C_6H_{10}O_5$) is the most abundant anhydrous monosaccharide
122 (Simoneit, 2002; Kuo et al., 2011; Hoffmann et al., 2010; Engling et al., 2006;),
123 which is tracked by other species of anhydromonosaccharides; e.g. mannosan (1,6-
124 anhydro- β -D-mannopyranose; $C_6H_{10}O_5$), galactosan (1,6-anhydro- β -D-
125 galactopyranose; $C_6H_{12}O_6$) and/or dehydroabietic acid ($C_{20}H_{28}O_2$). Such specific
126 factors and the sources (i.e., distribution) can make levoglucosan a unique tracer
127 (Jordan et al., 2006; Simoneit et al., 1999) in the source regions of southern Alaska
128 because the saddle of the Aurora Peak is far from the biomass burning source regions,
129 as shown in Figure 1.

130 3.1 Levoglucosan

131 This study showed that concentrations of levoglucosan are 8.6 times higher
132 (range: BDL-20800, average: 543 ± 2340 ng/L) than those of dehydroabietic acid
133 (range: BDL-556, ave. 62.0 ± 97.2 ng/L) and four hundred times higher than those of
134 vanillic ($C_8H_8O_4$) acid (range: BDL-18.6, ave. 1.51 ± 2.96 ng/L) for 1665-2008. It
135 should be noted that combustion of lignite (lignite includes fossilized cellulose) or
136 hemicellulose emits levoglucosan and its isomers; e.g., mannosan and galactosan (Kuo

137 et al., 2011; Hoffmann et al., 2010). However, we did not detect these isomer
138 compounds at a significant concentration (ranges: BDL-0.0) in this study. Thus,
139 levoglucosan/mannosan mass ratios (L/M) could be relatively high. In contrast many
140 aerosol samples showed significant concentrations of these isomers and levoglucosan
141 are reported in many aerosol samples collected from the oceans via “round-the-world
142 cruise” (Fu et al., 2011), Mt. Tai in the North China Plain (Fu et al., 2008), and urban
143 tropical India (Fu et al., 2010).

144 It should be noted that higher ratios of levoglucosan (L) to mannosan (M)
145 indicated a significant contributions of deciduous forest fire activities (Kawamura et
146 al., 2012). For example, Kawamura et al. (2012) reported very low ratios of L/M
147 (range: 3.3 – 5.0) for an ice core of the Kamchatka Peninsula in Northeast Asia
148 compared to lignite burning (30-90) at 200° C (Kuo et al., 2011), and aerosols samples
149 of Gosan site in south Korea (15-40, ave. 21) (Simoneit et al., 2004), suggesting
150 gymnosperm sources for anhydrosugars (Kawamura et al., 2012). Hence, we cannot
151 discuss more about the contributions of deciduous forest fire activities for our ice core
152 from the source regions of southern Alaska.

153 Insignificant concentrations of mannosan and galactosan in our ice core
154 indicate that combustion of lignite in the source regions of southern Alaska was minor.
155 These results suggest that contribution of lignite burning from East Asia, Eastern
156 Russia, Siberia, higher latitudes of Alaskan regions, Japan, and Canadian regions to
157 the ice core site was not significant. In contrast, western North Pacific ice core records
158 from the Kamchatka Peninsula (Kawamura et al., 2012) showed these anhydrosugars.
159 This suggests that western and eastern North Pacific regions could be influenced by
160 different air mass chemistry (e.g. lignite burning plume did not influence the southern
161 Alaskan glaciers) corresponding to other BB tracers. It should be noted that the

162 Kamchatka Peninsula's L/M ratios (range, 3.3-5.0) are close to those of gymnosperm
163 (conifer) burning. This is an evidence to suggest that lignite burning didn't alter the
164 Alaskan glacier's chemistry for 1665-2008.

165 It should be noted that degradation fluxes of levoglucosan in cloud droplets
166 and aqueous particles (deliquescent particles) by OH radicals have been reported
167 recently. For example, mean degradation fluxes were around $7.2 \text{ ng m}^{-3} \text{ h}^{-1}$ in
168 summer and $4.7 \text{ ng m}^{-3} \text{ h}^{-1}$ in winter (Hoffmann et al., 2010). Hence, we can
169 speculate that levoglucosan could be more stable compared to isomer compounds,
170 whose degradation fluxes are lower than 7.2 and/or $4.7 \text{ ng m}^{-3} \text{ h}^{-1}$ (e.g., Fraser and
171 Lakshmanan, 2000; Hoffmann et al., 2010) during long-range atmospheric transport
172 from source points to southern Alaska. Stability of levoglucosan is further confirmed
173 in an aerosol chamber study with atmospheric lifetime of 0.7-2.2 days in summer
174 (Hennigan et al., 2010). These results demonstrate the biomass burning emissions in
175 source apportionment for the saddle of the APA.

176 Levoglucosan showed higher concentrations in around 1660s-1830s (Figure
177 2a) with sporadic peaks in 1678 (ice core depth in meter: 174.6 and concentration 593
178 ng/L), 1692 (172.2 m; 704), 1695 (170.3 m; 1250), 1716 (165.6 m; 990), 1750 (156.7
179 m; 913), 1764 (151.5 m; 1433), 1786 (147.3m; 7057), 1794 (146.1 m; 3302) and
180 1834 (138.4m; 944) above its average concentration (542 ng/L). These higher spikes
181 could be related to forest fire activities in the source regions of southern Alaska.
182 Source regions could be East Asia, Eastern Russia, Siberia, higher latitudes of
183 Alaskan regions, Japan, and Canadian regions (Yasunari and Yamazaki, 2009). For
184 instance, Ivanova et al. (2010) reported the frequency of heavy forest fires (e.g., borel
185 forest) in spring, summer and autumn in eastern Siberia, which is a potential source to
186 Alaska (Yasunari and Yamazaki, 2009). This study showed higher concentrations of

187 levoglucosan before 1840s (Figure 2a). Marlon et al. (2008) further confirmed that
188 there was heavy biomass burning between 1750s -1840s on a global scale, which is
189 linked to increasing anthropogenic activities (e.g., population growth and land-use
190 change).

191 Similarly, we detected high spikes in 1898 (120.7m; 577 ng/L), 1913 (114.8m;
192 20800), 1966 (77.7m; 692) and 2005 (13.7m; 598) above the average concentration
193 (542 ng/L). Figure 2a clearly shows lower concentrations level of Levoglucosan (less
194 than 542 ng/L) after 1830s (except for 1898, 1913, 1966 and 2005) compared to
195 before 1830s. This could be attributed to intensive grazing, agriculture and forest fire
196 management (Marlon et al., 2008; Eichler et al., 2011). It should be noted that
197 charcoal signals are scarce for Siberian regions compared to Northern American and
198 European ice core records (Eichler et al., 2011). We did not detect significant
199 concentrations of any isomers as we have discussed above. Moreover, two thirds of
200 Earth's boreal forest (17 million km²) lies in Russia, which is a potential source of
201 forest fires that could have significance on a global scale (Eichler et al., 2011; Isaev et
202 al., 2002).

203 Mt. Logan Canada, GISP2, and 20D (older than 1850s) ice core records of
204 Greenland are characterized by higher spikes of NH₄⁺ superimposed with a relatively
205 uniform summertime and wintertime minimum (Whitlow et al., 1994). These suggest
206 that ice core NH₄⁺ has common sources in the circumpolar regions. We got higher
207 spikes of levoglucosan before 1840s (Figure 2a), which is consistent with higher
208 spikes of NH₄⁺ in 1770-1790 and 1810-1830 in the Mt. Logan data (e.g., Whitlow et
209 al., 1994). This comparison suggests similar source regions of NH₄⁺ for different
210 sampling sites. In contrast, Mt. Logan data showed higher spikes of NH₄⁺ in the
211 intervals of 1850-1870 and 1930-1980, which is dissimilar (except for two points) to

212 our results from Aurora Peak (Figure 2a). It should be noted that Greenland records
213 (GISP2 and 20D) showed lower spikes of NH_4^+ compared to Mt. Logan (Whitlow et
214 al., 1994) during these intervals (1850-1870 and 1930-1980), which is consistent to
215 the results of Aurora Peak (except for 1966), again suggesting similar source regions
216 (Whitlow et al., 1994; Davidson et al., 1993; Holdsworth et al., 1992). The potential
217 source regions for Greenland ice cores include northern North America, Europe and
218 Siberia. Simialry, Siberia, Alaska and British Columbia are likely source regions for
219 Mt. Logan (Whitlow et al., 1994; Davidson et al., 1993; Holdsworth et al., 1992).

220 Except for a few points, e.g., 1999 (436 ng/L) and 2005 (598 ng/L)),
221 concentrations of levoglucosan drastically decreased in 1980-2008. This infers that
222 forest fire activities could be controlled by many factors. For instance, Central and
223 East Siberian forest fire activities were controlled by strong climate periodicity, e.g.,
224 Arctic Oscillation (AO), El Nino, intensification of the hydrological cycle in central
225 Asia, and other human activities in the NH (Eichler et al., 2011; Robock, 1991;
226 Achard et al., 2008; Balzter et al., 2007; Wallenius et al., 2005). Eichler et al. (2009)
227 further confirmed that from 1816 to 2001 higher amounts of NH_4^+ and formate
228 (HCOO^-) were directly emitted from biogenic sources rather than biomass burning
229 (Olivier et al., 2006) in the Belukha glacier in the Siberian Altai mountains. Similarly,
230 lower concentrations of charcoal between 1700 and 2000 in this Altai mountain
231 further suggest that forest fire activities were stronger than anthropogenic activities in
232 the source regions (Eichler et al., 2011).

233 Similarly, the sparsity of NH_4^+ spikes after 1920 in Greenland (GISP2 and
234 20D) suggest low intensity of biomass burning and/or significant deposition before
235 reaching Greenland from North America (Whitlow et al., 1994). This is similar to the
236 saddle of Aurora Peak, except for 1910 (20800 ng/L), which may be due to a point

237 source around Alaskan region. Higher spikes of NH_4^+ at Mt. Logan during 1900-1990
238 are likely originated from central and eastern Siberia (Robock, 1991), which is
239 dissimilar to the source regions in this study. Only the exception is 1966 (2000 ng/L),
240 suggesting that local biomass burning is also important in southern Alaska.

241 Above results and discussions suggest the subsequent evidences: (a) heavy
242 biomass burning could be activated in the source regions; (b) short range air mass
243 circulation could quickly reach southern Alaska, causing higher concentration of
244 levoglucosan; (c) dilution and/or scavenging of biomass plume enroute could be
245 maximized after 1830s; (d) a common NH summertime biomass burning plume (e.g.,
246 same ice core records of SO_4^{2-} , NO_3^- , NH_4^+ showed significant concentrations during
247 same periods) could be significantly deposited by short range atmospheric circulation
248 on the exposed surface area of the glaciers. These special events further suggest that
249 Alaskan glaciers can not preserve most biomass burning events in the circumpolar
250 regions, which occurred in the source regions of Siberian and North America.

251 Hence, these historical records of levoglucosan before the 1830s suggest long
252 range atmospheric transport rather than short range transport from heavy forest fires.
253 For instance, forest fire intensity in 1660s-1830s could be induced by lightning during
254 drought seasons in the Siberian regions as well as extensive burning to clear land for
255 agriculture purposes in the NH (Whitlow et al., 1994 and reference therein). Declined
256 concentrations of levoglucosan trend after the 1830s (except for few points), showing
257 that sources could be changed significantly and/or forest fire activities could be
258 suppressed and/or controlled in 1830s-1980s (Whitlow et al., 1994). It should be
259 noted that mid to late 1800s are considered as the Little Ice Age (Mayewski et al.,
260 1993). Moreover, recent changes of the concentration trends in the Alaskan source
261 regions is thought to be climate driven (Whitlow et al., 1994 and reference therein).

262 3.2 Dehydroabietic acid

263 Dehydroabietic acid is produced by pyrolytic dehydration of abietic acid from
264 conifer resin. In other words, dehydroabietic acid is produced during the burning process
265 of conifer resins (Kawamura et al., 2012; Simoneit et al., 1993). It can be used as a
266 specific biomass-burning tracer for conifer trees and/or soft wood burning in an ice
267 core study. Dehydroabietic acid was detected as the second dominant species (range:
268 BDL-556, ave. 62.4 ± 97.2 ng/L), whose concentrations are 9 times lower than
269 levoglucosan but more than 46 times higher than vanillic acid (range: BDL-18.6, ave.
270 1.51 ± 2.96 ng/L). Dehydroabietic acid showed higher spikes in 1678 (ice core depth in
271 meter, 173.9m; 200 ng/L), 1716 (165.3 m; 67.5), 1728 (161.5 m; 139), 1732 (159.6
272 m; 233), 1738 (158.3 m; 113), 1750 (156.7 m; 66.9), 1764 (151.5 m; 331), 1786
273 (147.3 m; 386), 1794 (146.1 m; 78.6), 1913 (114.8 m; 101), and 1994-2007 (depth is
274 44.8-0.88 m), respectively having 92.8, 199, 141, 203, 136, 109, 98.4, 124, 174, 121,
275 298, and 555 ng/L.

276 These periods are consistent with those of higher spikes of levoglucosan,
277 except for a few points (e.g., 1734-1738) before 1990 (Figure 2a, b). The historical
278 trend of dehydroabietic acid concentrations is also similar to that of levoglucosan
279 concentrations before 1980, which is similar to Kamchatka ice core records. In
280 contrast, Kamchatka showed gradual increase of dehydroabietic acid (Figure 2b) after
281 the 1950s (e.g., Kawamura et al., 2012). These results suggest that biomass burning
282 plumes of pine, larch, spruce and fir trees in Siberian regions (Kawamura et al., 2012;
283 Ivanova et al., 2010) could not reach southern Alaska significantly compared to
284 Kamchatka, south eastern Russia.

285 Dehydroabietic acid concentrations after the 1980s were higher than
286 levoglucosan, which is similar to Kamchatka records. This further suggests that

287 biomass burning plumes from Siberian boreal conifer trees could be transported to the
288 North Pacific regions (Kawamura et al., 2012). It also suggests that East Asian
289 regions (broad-leaf trees are common) could be important for levoglucosan rather
290 than dehydroabietic acid (boreal forest fires in Siberia, i.e., pine trees). It should be
291 noted that Alaska can receive different air masses from East Asia, Eastern Russia,
292 Siberia, higher latitudes of Alaskan regions, Japan, and Canadian regions in the
293 troposphere (>300 hPa) (Yasunari and Yamazaki, 2009) and Kamchatka-Peninsula
294 also can receive air masses from Siberia, Far East, North China and Eastern Europe
295 (Kawamura et al., 2012).

296 These results showed some similarity between levoglucosan records of
297 Kamchatka and Alaska (except for few points) and some discrepancy between
298 dehydroabietic acid records between these sampling sites. Kamchatka showed gradual
299 increase after the 1950s. Alaska showed this after the 1980s, suggesting that conifer-
300 burning plumes could be transported significantly to Kamchatka, but not southern
301 Alaska, in the 1950s – 1980s. There is another possibility for this particular
302 discrepancy of Kamchatka and Alaska: dehydroabietic acids could be decomposed
303 during long-range transport (Kawamura et al., 2012; Simoneit and Elias, 2001) from
304 Siberia before reaching southern Alaska (i.e. eastern North Pacific ice core) but not
305 before reaching Kamchatka (i.e. western North Pacific). The Kamchatka ice core also
306 doesn't show high spikes (except 1970) in the 1950s-1970s compared to before and
307 after those decades. Moreover, a correlation of levoglucosan with dehydroabietic acid
308 from 1665-1918 ($R = 0.74$) is better than from 1918-1977 (0.13) and 1977-2007
309 (0.36). These relations are weaker (0.39, 0.04, and 0.22, respectively) for vanillic acid,
310 except for 1913 and 1966 at all cases. The representing figures are shown in Figure
311 3a-c. Such types of lower spikes and/or sporadic peaks of levoglucosan and

312 dehydroabietic acid after the 1920s (Figure 2a,b) and these correlations suggest that
313 source regions should be different (e.g. east Asian broad leaf trees and Siberian source,
314 e.g. boreal forest/pine trees), and long range atmospheric transport is insignificant for
315 these historical concentration trends of dehydroabietic acid rather than levoglucosan
316 over the saddle of Aurora Peak at least after the 1920s. Annual composite maps
317 (Figure 5a-f) since 2001 to 2008 of the Moderate Resolution Imaging
318 Spectroradiometer (MODIS) supported our above results and discussion. For example,
319 levoglucosan (in 2005, 2006 and 2004 AD with 598.0, 130.8, and 95.30ng/L,
320 respectively), dehydroabietic acid (in 2007, 2004, and 2006 AD with 555.9, 309.7, and
321 298.1ng/L, respectively) and vanillic acid (in 2005, 2007 and 2006 with 18.57, 12.66,
322 and 7.27ng/L) showed discrepancy of higher spikes in the same years (Figure 5a-f)
323 suggested that they have different sources in the same years.

324 **3.3 Vanillic acid**

325 We detected vanillic acid (VA) in an ice core of the Aurora Peak (Figure 2c),
326 which is a biomass burning tracer of lignin (Simoneit et al., 1993). Particularly, VA
327 can be produced by incomplete combustion of conifer trees, i.e., conifer rich boreal
328 forest (Pokhrel, 2015; Simoneit et al., 1993). Figure 2c shows sporadic peaks of
329 lignin in 1672 (2.23 ng/L), 1678 (3.25), 1692 (3.23), 1695 (5.56), 1698 (1.50), 1732
330 (3.98), 1764 (1.56), 1786 (3.65), 1794 (1.35), 1814 (11.0), 1818 (5.50), 1913 (2.12),
331 1973 (5.52), 1989 (3.57), 1993 (2.66), 1996 (4.66), 1997 (3.57), 1999 (3.57), 2001
332 (3.26), and 2003-2007 (2.36, 2.07, 18.6, 7.27 and 12.6ng/L, respectively). We found
333 similar spikes of VA and levoglucosan during these periods (except for few points,
334 e.g., 2004, 2006 and 2007). The Kamchatka ice core showed similar types of high
335 spikes, except for a few points (e.g., 1972 and 1992).

336 Similarity of higher spikes suggests that biomass combustion sources (e.g.,
337 woody parts of trees) and source regions could be similar (Kawamura et al., 2012),
338 that is, lignin and cellulose source regions of southern Alaska were simultaneously
339 significant, before the 1920s. This result infers long-range atmospheric transport was
340 insignificant at least after the 1920s, which could be somewhat similar to the
341 dehydroabietic acid as we have discussed above sections. For example, the
342 correlations (Figure 3a-c) between dehydroabietic acid and vanillic acid ($R \geq 0.80$) is
343 better than those of levoglucosan with dehydroabietic acid (0.36) and vanillic (except
344 for, 1999 and 2005) acid (0.22) after the Great Pacific Climate Shift (1977-2007). The
345 mean concentrations of dehydroabietic (127.9 ng/L-ice) and vanillic (2.29 ng/L-ice)
346 acids are secure with standard deviations (± 126 and ± 3.04 , respectively) compared to
347 levoglucosan (ave. 90.8 ± 146 ng/g-ice) from 1977-2007. It suggests a short range
348 atmospheric transport, which could be from climate driven (Pokhrel et al., 2015b).

349 In other words, dehydroabietic acids and p-hydroxybenzoic acid (p-HBA)
350 could be more unstable compared to photo-degradation of levoglucosan during long
351 range transport. For instance, higher sensitivity of dehydroabietic acid was reported
352 compared to levoglucosan (Simoneit et al., 2002; Simoneit and Elias, 2001). It should
353 be noted that we did not detect p-HBA from the same ice-core sample, which can be
354 produced from incomplete combustion of grasses (Kawamura et al., 2012; Simoneit et
355 al., 2002). In contrast, we detected significant amounts of dehydroabietic acid from
356 1665-2007 (Figure 2b). Hence, we may speculate that p-HBA could be more unstable
357 compared to levoglucosan, dehydroabietic acid, and vanillic acid.

358 **3.4 Comparison with ammonium, nitrite, nitrate and SO_4^{2-}**

359 There are many studies of organic compounds and major inorganic ions of
360 biomass burning for aerosol samples in the NH, which are reported elsewhere

361 (Kunwar et al., 2016; Zhu et al., 2015; Cong et al., 2015; Kunwar and Kawamura,
362 2014; Lazaar et al., 2011; Kundu et al., 2010; Wang et al., 2009). In addition,
363 terephthalic acid could be a special tracer of plastic waste burning (Kawamura and
364 Pavuluri, 2010; Pavuluri et al., 2010; Kunwar and Kawamura, 2014b). Particularly,
365 ammonium (NH_4^+), nitrite (NO_2^-), nitrate (NO_3^-) and sulfate (SO_4^{2-}) were used to
366 better understand the atmospheric signal of biomass burning and/or the Pioneer
367 Agriculture Revolution (PIA-GREV) in the NH. These results are reported elsewhere
368 (Holdsworth et al., 1996, Legrand and Mayewski, 1997). For instance, a signal of
369 biomass burning is ammonium (e.g., $(\text{NH}_4)_2\text{SO}_4$) in snow particles, which is a
370 constituent of forest fire smoke (Holdsworth et al., 1996; Tsai et al., 2013 and
371 references therein).

372 Similarly, levoglucosan is a unique biomass burning tracer (Simoneit, 2002).
373 We found weak correlations (R) of levoglucosan with NO_2^- (0.06), NO_3^- (0.04), nss-
374 SO_4^{2-} (0.08), nss- K^+ (0.11), nss- Ca^{2+} (0.072), and NH_4^+ (0.11) (Figure 4a-d), except
375 for a few points (e.g., 1998 and 1999). The correlations of MSA^- with NO_3^- (0.64),
376 unsaturated fatty acids, e.g., oleic ($\text{C}_{18:1}$) acid (0.70), and with other anions (nss- SO_4^{2-} ,
377 Cl^- , F^- , and Na^+) are strong (≥ 0.71), suggesting that major ions can not represent
378 pristine biomass-burning signals at least in the North Pacific rim (NPR) (Pokhrel,
379 2015; Pokhrel et al., 2016). The multi-decadal cycles of NO_2^- , SO_4^{2-} and CH_3SO_3^-
380 from the same ice core may be controlled by climate variability and/or climate driven
381 forces in the NPR (Pokhrel, 2015; Pokhrel et al., 2016; Whitlow et al., 1994;).
382 Moreover, the historical trend of vanillic acid from 1800-2000 for Greenland ice core
383 (McConnell et al., 2007) is completely different with this study. Hence, this study
384 reveals a new dimension of biomass burning periodic cycles in the NPR, which can
385 alter the concept of other ice core studies in the NH.

386 4. Summary and Conclusions

387 Levoglucosan (ave. 543 ± 2343 ng/L), dehydroabietic (62.4 ± 97.2 ng/L) and
388 vanillic acid (1.36 ± 3.03 ng/L) are present in the ice core from saddle of Aurora Peak
389 in Alaska. They have been reported to better understand temporal trends of biomass
390 burning activities in the source region of southern Alaska. Levoglucosan showed
391 sporadic peaks during the 1660s-1830s, 1898, 1913, 1966, and 2005. Dehydroabietic
392 and vanillic acid showed similar historical trends with levoglucosan at least before the
393 1970s. Historical trends of levoglucosan, dehydroabietic acid, and vanillic acid
394 showed that biomass burning activities from resin and lignin boreal conifer trees and
395 other higher plants/grasses were significant before the 1830s and after the 1970s in
396 the source regions of southern Alaska, which is different with earlier study from
397 Kamchatka ice core. Correlations of levoglucosan with NO_2^- ($r=0.06$), NO_3^- (0.04),
398 nss-SO_4^{2-} (0.08), nss-K^+ (0.11), nss-Ca^{2+} (0.072), and NH_4^+ (0.11) from the same ice
399 core suggest that these anions and cations can not represent the gleaming signal of
400 biomass burning activities in the source regions for southern Alaska. These results
401 further suggest that forest fire signals in the NH are dependent on the source regions
402 and ice core sampling sites. Hence, it inquires about the long-range and/or short-range
403 atmospheric transport, which will be important for biomass burning tracers (i.e.,
404 levoglucosan, dehydroabietic and vanillic acid), cations, and anions.

405 Author contributions.

406 KK designed the research. TS and SM conducted ice core drilling. AT conducted ice
407 core dating. AP, KO and OS worked on ice core cutting for chemical analysis. AP
408 analyzed ice sections and BK supported data analysis. AP and KK wrote the
409 manuscript.

410 Acknowledgements

632

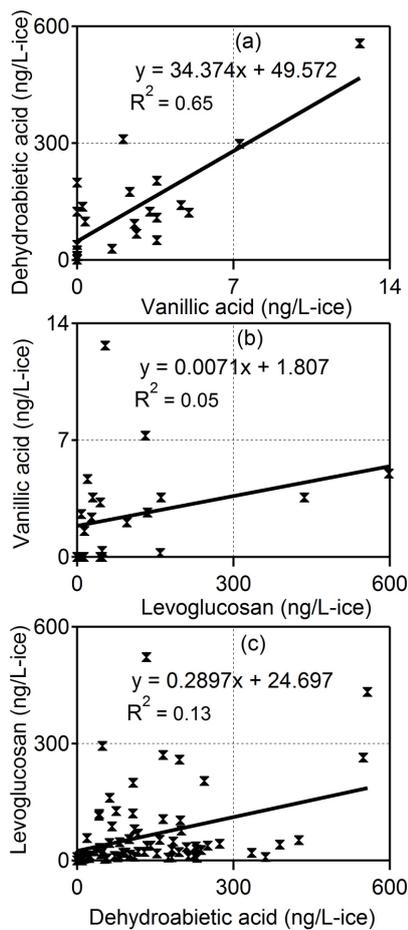

633

634 Figure 1. Geographical location of Aurora Peak in Alaska, where 180-meter long ice
635 core was drilled on the saddle of this peak in 2008¹⁶ (Pokhrel, 2015).

636

637 Figure 2. Concentration changes of (a) levoglucosan, (b) dehydroabietic, and (c)
638 vanillic acids in the ice core collected from Aurora Peak in Alaska for 1665-2008.

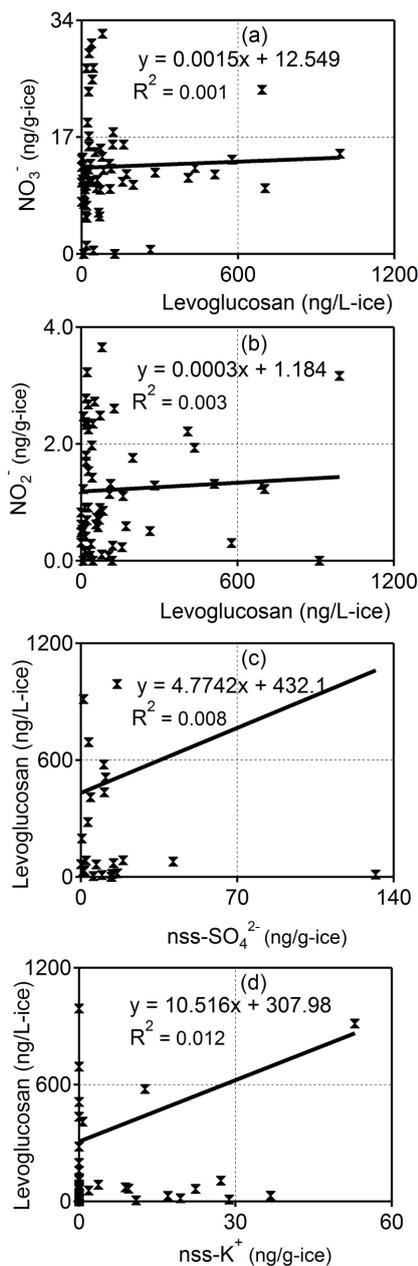

639

640 **Figure 3.** Correlations between the concentrations of (a) dehydroabiatic and vanillic
641 (b) vanillic and levoglucosan, and (c) levoglucosan and dehydroabiatic acid in the
642 Alaska ice core records collected from the saddle of Aurora Peak after the Great
643 Pacific Climate Shift (1977-2007).

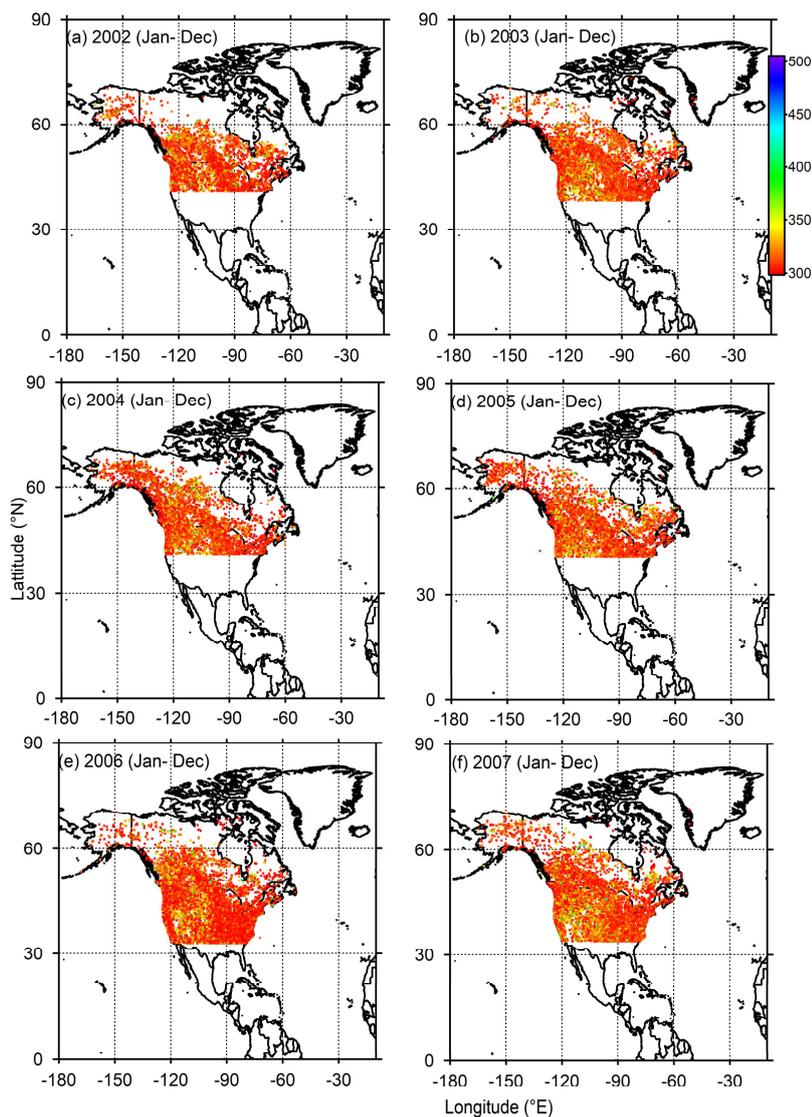

644

645

646

647 Figure 4. Correlations of the concentrations of (a) NO_3^- , (b) NO_2^- , (c) nss-SO_4^{2-} , and
648 (d) nss-K^+ with levoglucosan in the Alaskan ice core samples collected from saddle of
649 Aurora Peak (1665-2007).

650

651 Figure 5. The MODIS fire spot (a-f) of Alaskan regions since 2001 to 2007, when
652 levoglucosan (2005, 2006, and 2004 AD), dehydroabietic (2007, 2004, and 2006) and
653 vanillic (2005, 2007 and 2006) acids showed higher spikes in order to first, second
654 and third positions, respectively.
