22 **Abstract**

23 Ammonia (NH₃), as an alkaline gas in the atmosphere, can cause direct or indirect
24 effects on the air quality, soil acidification, climate change as well as human health.
25 Estimating surface NH₃ concentrations is critically important for modelling the dry
26 deposition of NH₃ and for modelling the formation of ammonium nitrate, which have
27 important impacts on the natural environment. However, sparse monitoring sites make

28 it challenging and difficult to understand the global distribution of surface NH_3
29 concentrations both in time and space. We estimated the global surface NH_3
30 concentrations for the years of 2008-2016 using the satellite NH_3 retrievals combining
31 its vertical profiles from the GEOS-Chem. The accuracy assessment indicates that the
32 satellite-based approach has achieved a high predictive power for annual surface NH_3
33 concentrations compared with the measurements of all sites in China, US and Europe
34 ($R^2=0.76$ and $\text{RMSE}=1.50 \mu\text{g N m}^{-3}$). The satellite-derived surface NH_3
35 concentrations had higher consistency with the ground-based measurements in China
36 ($R^2=0.71$ and $\text{RMSE}=2.6 \mu\text{g N m}^{-3}$) than the US ($R^2=0.45$ and $\text{RMSE}=0.76 \mu\text{g N m}^{-3}$)
37 and Europe ($R^2=0.45$ and $\text{RMSE}=0.86 \mu\text{g N m}^{-3}$) at a yearly scale. Annual surface
38 NH_3 concentrations higher than $6 \mu\text{g N m}^{-3}$ are mainly concentrated in the North
39 China Plain of China and Northern India, followed by $2\text{-}6 \mu\text{g N m}^{-3}$ mainly in
40 southern and northeastern China, India, western Europe and eastern United States
41 (US). High surface NH_3 concentrations were found in the croplands in China, US and
42 Europe, and surface NH_3 concentrations in the croplands in China were approximately
43 double than those in the croplands in the US and Europe. The linear trend analysis
44 shows that an increase rate of surface NH_3 concentrations ($>0.2 \mu\text{g N m}^{-3} \text{ y}^{-1}$)
45 appeared in the eastern China during 2008-2016, and a middle increase rate ($0.1\text{-}0.2$
46 $\mu\text{g N m}^{-3} \text{ y}^{-1}$) occurred in northern Xinjiang over China. NH_3 increase was also found
47 in agricultural regions in middle and eastern US with an annual increase rate of lower
48 than $0.10 \mu\text{g N m}^{-3} \text{ y}^{-1}$. The satellite-derived surface NH_3 concentrations help us to
49 determine the NH_3 pollution status in the areas without monitoring sites and to
50 estimate the dry deposition of NH_3 in the future.

51 **Introduction**

52 Ammonia (NH_3), emitted primarily by agricultural activities and biomass burning, is
53 an important alkaline gas in the atmosphere (Van Damme et al., 2018; Warner et al.,
54 2017). Excessive surface NH_3 concentrations can cause chronic or acute damage to
55 the plant (such as reduced growth and bleached gray foliage) when its capacity of
56 detoxification is exceeded (Eerden, 1982; Sheppard et al., 2008). Estimation of surface

57 NH₃ concentrations is critically important in modelling the dry deposition of NH₃,
58 which may comprise a large part of atmospheric nitrogen (N) deposition, and could
59 cause acidification in the soil, eutrophication in the aquatic ecosystems, and
60 contamination in drinking water (Basto et al., 2015;Kim et al., 2014;Lamarque et al.,
61 2005;Larssen et al., 2011;Reay et al., 2008). In addition, NH₃ can also react with
62 nitric acid and sulfuric acid to form ammonium salts (Li et al., 2014;Li et al., 2017b),
63 which are important components of particulate matters (PM), and have negative
64 impacts on air quality and human health (Xu et al., 2017;Schaap et al., 2004).

65 Several national monitoring programs [can measure](#) surface NH₃ concentrations,
66 including the Chinese Nationwide Nitrogen Deposition Monitoring Network
67 (NNDMN) established in 2004, the Ammonia Monitoring Network in China
68 (AMoN-China) established in 2015 in China, the Ammonia Monitoring Network in
69 the US (AMoN-US) as well as the European Monitoring and Evaluation Programme
70 (EMEP). However, there are still relatively large uncertainties of estimating global
71 surface NH₃ concentrations, resulting from the sparse monitoring sites as well as the
72 limited spatial representativeness (Liu et al., 2017b;Liu et al., 2017a). Satellite NH₃
73 retrievals are an important complement to gain the global distribution of NH₃
74 concentrations with a high spatial resolution (Van Damme et al., 2014c). NH₃ can be
75 measured by several satellite instruments including the Infrared Atmospheric
76 Sounding Interferometer (IASI), Atmospheric Infrared Sounder (AIRS), Cross-track
77 Infrared Sounder (CrIS) and Tropospheric Emission Spectrometer (TES). TES using
78 the thermal infrared spectral range has sparser spatial coverage compared to IASI,
79 CrIS and AIRS (Shephard et al., 2011;Zhang et al., 2017a). A recent study (Kharol et
80 al., 2018) reported the dry NH₃ depositions in North America, and found -15%
81 underestimation in CrIS surface NH₃ concentrations (using three fixed NH₃ profiles
82 considering unpolluted, moderate and polluted conditions) compared with the
83 measurements from the AMoN-US during the warm months (from April to
84 September). Warner et al. reported the global AIRS NH₃ concentrations at 918hPa
85 (approximately 700-800 m) at 1° latitude × 1° longitude grids, and found NH₃
86 concentrations increased in the major agricultural regions during 2003-2015 (Warner

87 et al., 2017). The IASI NH₃ measurements have been validated with NH₃ columns
88 measured by the Fourier transform infrared spectroscopy (FTIR), ground-based NH₃
89 measurements, NH₃ emissions and atmospheric chemistry transport models (CTMs)
90 (Dammers et al., 2016; Van Damme et al., 2014c; Van Damme et al., 2014a; Whitburn
91 et al., 2016).

92 Apart from satellite retrievals, CTMs are also powerful tools to investigate
93 spatiotemporal variability of surface NH₃ concentrations in the atmosphere. Schiferl et
94 al. evaluated the modelled NH₃ concentrations during 2008-2012 from GEOS-Chem,
95 and found an approximately 26% underestimation compared with the ground-based
96 measurements, which can be related to the relatively large uncertainties in NH₃
97 emissions used for driving GEOS-Chem (Schiferl et al., 2015). Zhu et al. used the
98 GEOS-Chem constrained by TES measurements to estimate surface NH₃
99 concentration during 2006-2009, and found an improvement in comparison with the
100 ground-based measurements in the United States (Zhu et al., 2013). Schiferl et al.
101 used the airborne observations to validate the simulated NH₃ concentrations in 2010
102 from GEOS-Chem, and revealed reasonably simulated NH₃ vertical profiles compared
103 with the aircraft measurements but with an underestimation in surface NH₃
104 concentrations in California (Schiferl et al., 2014). A number of previous studies have
105 used satellite NO₂ columns to estimate the surface NO₂ concentrations combining
106 NO₂ vertical profiles from CTMs (Geddes et al., 2016; Lamsal et al., 2013; Nowlan et
107 al., 2014; Liu et al., 2017c). The methods of using the vertical profiles to convert
108 satellite-retrieved columns to surface concentrations have been proven successful for
109 SO₂ and NO₂ (Geddes et al., 2016; Geng et al., 2015; Lamsal et al., 2008; Nowlan et al.,
110 2014). CTMs can provide valuable information of NH₃ vertical profiles (Whitburn et
111 al., 2016; Liu et al., 2017b), and IASI-derived surface NH₃ concentrations combining
112 NH₃ vertical profiles from CTMs in China and Europe were evaluated previously (Liu
113 et al., 2017b; Graaf et al., 2018). This study followed these studies to estimate the
114 satellite-derived global surface NH₃ concentrations using IASI NH₃ retrievals and the
115 vertical profiles from GEOS-Chem, and the present study aims to estimate the global
116 surface NH₃ concentration from a satellite perspective.

117 **Data and Methods**

118 **IASI NH₃ measurements**

119 The Infrared Atmospheric Sounding Interferometer (IASI) is a passive instrument
120 measuring infrared radiation within the spectral range of 645-2769 cm⁻¹. The IASI-A
121 instrument is on board of the MetOp-A satellite launched in 2006 covering the globe
122 twice a day with an elliptical spatial resolution of approximately 12 by 12 kilometers,
123 and cross the equator at 09:30 and 21:30 local times (Van Damme et al., 2014b). We
124 used the daytime IASI NH₃ measurements due to the larger positive thermal contrast
125 detected by satellite instruments leading to smaller errors compared to the nighttime
126 data (Van Damme et al., 2014b). In this work, we used the IASI NH₃ columns
127 products (ANNI-NH3-v2.2R-I) during 2008-2016 (Van Damme et al., 2017) to
128 estimate the global surface NH₃ concentrations. The ANNI-NH3-v2.2R-I datasets
129 were developed by converting spectral HRI (hyperspectral range index) to NH₃
130 columns through an Artificial Neural Network for IASI (ANNI) algorithm (Whitburn
131 et al., 2016). This algorithm considered the influence of the NH₃ vertical profiles,
132 pressure, humidity and temperature profiles. The NH₃ vertical profile information
133 used to generate the ANNI NH₃ columns were retrieved from GEOS-Chem, which
134 integrates H₂SO₄-HNO₃-NH₃ aerosol thermodynamics mechanism (Whitburn et al.,
135 2016;Van Damme et al., 2017). [The ANNI-NH3-v2.2R-I datasets used the ANNI
136 algorithm and took account of the influence of NH₃ vertical profiles, pressure,
137 humidity and temperature profiles, which was to make the columns accurate. There is
138 no information on NH₃ vertical profiles in the ANNI-NH3-v2.2R-I datasets. The NH₃
139 vertical profiles used in this paper was to convert the columns to surface
140 concentrations and to make the surface NH₃ estimates accurate.](#) The IASI NH₃
141 columns used in this study were processed into the monthly data at 0.25 ° latitude ×
142 0.25 ° longitude grids by the arithmetic averaging method (Van Damme et al.,
143 2017;Whitburn et al., 2016;Liu et al., 2017a).

144 **Surface NH₃ measurements**

145 To evaluate our satellite-derived global surface NH₃ concentrations, we collected
146 available surface NH₃ measurements on a regional scale in 2014. In China, we used
147 the national measurements from the Chinese Nationwide Nitrogen Deposition
148 Monitoring Network (NNDMN) including 10 urban sites, 22 rural sites, and 11
149 background sites. Surface NH₃ concentrations in the NNDMN were measured by both
150 ALPHA (Adapted Low-cost, Passive High Absorption) and DELTA (Denuder for
151 Long-Term Atmospheric sampling) systems. The bias for monthly measurements at a
152 site using DELTA systems is as below approximately 10% (Sutton et al., 2001), and
153 the correlation between the ALPHA and DELTA measurements was highly significant
154 ($R^2=0.919$, $p<0.001$) (Xu et al., 2015). The detailed descriptions on the NNDMN have
155 been described in a previous study (Xu et al., 2015). In the US, we used the
156 measurements of 67 sites from the AMoN-US, downloaded from the website:
157 <http://nadp.sws.uiuc.edu/AMoN/>. Surface NH₃ concentrations in the AMoN-US were
158 measured by the radiello diffusive sampler (<http://www.radiello.com>) as a simple
159 diffusion-type sampler collected every 2 weeks, and these sites were generally
160 distributed at rural sites (Li et al., 2016). We calculated annual surface NH₃
161 concentrations by averaging all the measurements since we compared the measured
162 surface NH₃ concentrations with satellite-derived surface NH₃ concentrations at a
163 yearly scale. In Europe, we used the measurements of 43 sites from the EMEP
164 network (<https://www.nilu.no/projects/ccc/emepdata.html>). The EMEP is composed of
165 multiple national networks in Europe, thus the measurement systems differs among
166 different national networks. The overall bias of the different instruments in EMEP
167 varied from -30 to 10% for all sites (Bobruzki et al., 2010). Most sites in China, US
168 and Europe were set a height of 1-50 m above the ground (Xu et al., 2015; Li et al.,
169 2016; Puchalski et al., 2011).

170 **GEOS-Chem model**

171 We used GEOS-Chem version 11-01 as the chemical transport model to calculate

172 global NH₃ vertical profiles (using the year of 2014 as a case study in the results and
173 discussion). We did the spin up for 5 months, which well exceed the typical lifetime
174 of atmospheric NH₃ (typically within 24 hours) and aerosol ammonium ions (typically
175 within a week) (Pye et al., 2009). It has a spatial resolution of 2° latitude × 2.5°
176 longitude × 47 vertical layers spanning over Earth's surface and about 80 km above it.
177 It is driven by the meteorological field data of the GEOS-FP (forward-processing)
178 products, which were produced by NASA GMAO (Global Modelling and
179 Assimilation Office) (<https://gmao.gsfc.nasa.gov/>). Here we modelled the NH₃
180 vertical profiles using GEOS-Chem, and used the monthly averages for analysis. The
181 global NH₃ emissions in GEOS-Chem are based on the EDGAR (Emissions Database
182 for Global Atmospheric Research) v4.2
183 (<http://edgar.jrc.ec.europa.eu/overview.php?v=42>), while the regional emissions are
184 replaced with MIX inventory for East Asia (Li et al., 2017a)
185 (<http://www.meicmodel.org/dataset-mix.html>), EMEP inventory for Europe
186 (<http://www.emep.int/>), NEI (National Emissions Inventory, 2011) for the US
187 (<https://www.epa.gov/air-emissions-inventories>) and CAC (Criteria Air Contaminant)
188 inventory for Canada
189 (<https://www.canada.ca/en/services/environment/pollution-waste-management/national-pollutant-release-inventory.html>). The main difference between the regional
190 inventories and EDGAR is that seasonality of emissions is included in regional
191 inventories. The seasonality of regional emissions inventories is embedded as integral
192 part of the inventory except EMEP (Janssens-Maenhout et al., 2015;Crippa et al.,
193 2018;Lenhart and Friedrich, 1995). The biomass burning emissions are from Global
194 Fire Emissions Database (GFED4) including agricultural fires, wildfire and
195 pre-scribed burning (Giglio et al., 2013). The GEOS-Chem simulates a
196 comprehensive atmospheric NO_x-O₃-VOC-aerosol system (Mao et al., 2013). The
197 thermodynamic equilibrium of NH₃-H₂SO₄-HNO₃ system is simulated by the
198 ISORROPIA II model (Fountoukis and Nenes, 2007;Pye et al., 2009). The modelling
199 of wet deposition is described by a previous study (Liu et al., 2001) with updates from
200 the studies (Amos et al., 2012;Wang et al., 2011). Dry deposition of particles follows
201

202 the size-segregated treatment (Zhang et al., 2001) and gaseous dry deposition follows
203 the framework (Wesely, 1989) with updates from a previous study (Wang et al., 1998).
204 We archive the output daily averages of NH₃ concentrations as well as the averages
205 between 9 and 10 am, which corresponds to the local crossing time of IASI (9:30 am).
206 The local time is the time in a particular region or area expressed with reference to the
207 meridian passing through it. The relationship between NH₃ concentration at 9-10 am
208 and the daily averages derived from the GEOS-Chem was used to convert the satellite
209 observed NH₃ column to daily averages (Nowlan et al., 2014).

210 **Estimation of surface NH₃ concentrations**

211 We estimated global surface NH₃ concentrations using the IASI NH₃ columns as well
212 as the GEOS-Chem. We took into account the advantages of IASI NH₃ columns with
213 high spatial resolutions and the GEOS-Chem with vertical profiles. The IASI NH₃
214 data we gained are column data, and there is no information on the vertical
215 information. To convert the columns to surface concentrations, we used the widely
216 used modelled vertical profiles from GEOS-Chem. The GEOS-Chem outputs include
217 47 layers, which are not continuous in the vertical direction. To gain the continuous
218 vertical NH₃ profile, we used the Gaussian function to fit the 47 layers' NH₃
219 concentrations. The main advantage to simulate the vertical profiles is that the NH₃
220 concentration at any height indicated by satellite can be obtained. On the other hand,
221 the simulated profile function has a general rule, which can convert the columns
222 indicated by satellite to surface concentration simply and quickly for many years. The
223 height of each grid box used here was calculated at the middle height of each layer
224 rather than the top height of each layer. A three-parameter Gaussian function was used
225 to fit NH₃ vertical profiles at each grid box from the GEOS-Chem in the previous
226 studies (Whitburn et al., 2016; Liu et al., 2017b) :

$$227 \quad \rho = \rho_{max} e^{-\left(\frac{Z-Z_0}{\sigma}\right)^2} \quad (1)$$

228 where ρ is NH₃ concentrations at the layer height Z ; ρ_{max} is the maximum NH₃
229 concentrations at the height z_0 ; σ is an indicator for the spread or thickness of the

230 NH₃ concentrations.

231 This study expanded the equation (1) to fit NH₃ vertical profiles at each grid box by
232 the following equation (Liu et al., 2017b):

$$233 \quad \rho = \sum_{i=1}^n \rho_{max,i} e^{-\left(\frac{z-z_{0,i}}{\sigma_i}\right)^2} \quad (2)$$

234 where n ranges from 1 to 6. If n equals 1, the equation (2) is the same as the equation
235 (1); if n is greater than 1, the equation (2) is the multiple three-parameters Gaussian
236 items. We determined the value of n that can simulate the NH₃ vertical profiles with
237 best performance at each grid box using the determining coefficients of R-Square (R²).
238 Once the NH₃ vertical profiles were determined at each grid box, we can extrapolate
239 NH₃ concentrations at any height from the GEOS-Chem ($G_{GEOS-Chem}$).

240 We then aggregated the IASI NH₃ columns Ω_{IASI} (0.25 ° latitude × 0.25 ° longitude)
241 to the GEOS-Chem grid size $\overline{\Omega_{IASI}}$ (2 ° latitude × 2.5 ° longitude) by the averaging
242 method. We have the following equation (Lamsal et al., 2008):

$$243 \quad \overline{G_{IASI_{9-10}}} = \frac{G_{GEOS-Chem}}{\Omega_{GEOS-Chem}} \times \overline{\Omega_{IASI_{9-10}}} \quad (3)$$

244 where $\overline{G_{IASI_{9-10}}}$ is the satellite-derived surface NH₃ concentrations at a GEOS-Chem
245 grid size at 9-10am; $\frac{G_{GEOS-Chem}}{\Omega_{GEOS-Chem}}$ is the ratio of surface NH₃ concentrations to NH₃
246 columns calculated from GEOS-Chem; $\overline{\Omega_{IASI_{9-10}}}$ is the average IASI NH₃ columns
247 at a GEOS-Chem grid at 9-10am.

248 We found a high correlation (R=0.96 and p=0.000) between the surface NH₃
249 concentrations and NH₃ columns based on the GEOS-Chem outputs (**Fig. S1**). Then
250 we used the satellite-derived scaling factor to downscale the satellite-derived surface
251 NH₃ concentrations at a GEOS-Chem grid by using the following ratio:

$$252 \quad R_{IASI} = \frac{\Omega_{IASI}}{\overline{\Omega_{IASI}}} \quad (4)$$

$$253 \quad G_{IASI_{9-10}} = \overline{G_{IASI_{9-10}}} \times R_{IASI} \quad (5)$$

254 where R_{IASI} is the scaling factor. $G_{IASI_{9-10}}$ is the satellite-derived surface NH₃
255 concentrations at a satellite IASI grid size (0.25 ° latitude × 0.25 ° longitude) at 9-10am.
256 To convert the instantaneous satellite-derived surface NH₃ concentrations G_{IASI} to

257 daily average surface NH₃ concentrations, we followed the methods (Nowlan et al.,
258 2014):

$$259 \quad G_{IASI}^* = \frac{G_{GEOS-Chem}^{1-24}}{G_{GEOS-Chem}^{9-10}} \times G_{IASI_{9-10}} \quad (6)$$

260 where G_{IASI}^* is the daily average surface NH₃ concentrations, and $\frac{G_{GEOS-Chem}^{1-24}}{G_{GEOS-Chem}^{9-10}}$ is the
261 ratio of the GEOS-Chem surface NH₃ concentrations at the daily average to the
262 average of 9-10 am.

263 **Results and Discussion**

264 **NH₃ vertical profiles from GEOS-Chem**

265 NH₃ emitted from the surface can be transported horizontally or vertically, and its
266 concentrations may show a certain gradient in the vertical and horizontal directions
267 (Preston et al., 1997; Rozanov et al., 2005). There are generally two types of shapes of
268 NH₃ vertical profiles (**Fig. S2**) from aircraft measurements (Li et al., 2017b; Tevlin et
269 al., 2017) and CTMs (Whitburn et al., 2016; Liu et al., 2017b). One is representative
270 for the vertical profile with maximum NH₃ concentrations at a certain height ($z_0 > 0$)
271 and the other is representative for the vertical profile with maximum NH₃
272 concentrations near the earth surface ($z_0 = 0$). In this study, the vertical profiles of NH₃
273 were fitted based on the 47 layers' outputs by GEOS-Chem in 2014 at a monthly scale.
274 **Fig. S3** shows the spatial distribution of NH₃ concentrations in the first and fifth
275 layers simulated by GEOS-Chem in January 2014. NH₃ concentrations in the fifth
276 layer are significantly lower than those in the first layer, suggesting that NH₃
277 concentrations decrease with increasing layers (or altitude), especially in NH₃ hotspot
278 regions (such as eastern China, India, western Europe and eastern US). The average
279 difference of NH₃ concentrations between the first and fifth layers on the land is 0.34
280 $\mu\text{g N m}^{-3}$. The average NH₃ concentrations in the first and fifth layers in eastern China,
281 India, western Europe and eastern US were 2.76, 7.28, 0.55 and 0.31 $\mu\text{g N m}^{-3}$,
282 respectively.

283 To more vividly depict the vertical profiles of NH₃, we show NH₃ vertical

284 concentrations with cross-section drawn at 37°N in January, 2014 (**Fig. S4**). High NH₃
285 concentrations are mainly concentrated in the 1-10 layers, and show a significant
286 decrease trend with the increasing altitude, which is consistent with the aircraft
287 measurements (Preston et al., 1997;Lin et al., 2014;Levine et al., 1980;Shephard and
288 Cady-Pereira, 2015;Li et al., 2017b;Tevlin et al., 2017). NH₃ vertical profiles were
289 fitted by Gaussian function (2-6 terms) based on the 47 layers' NH₃ concentrations
290 from the GEOS-Chem, and the fitting accuracy was determined by R². We found that
291 the NH₃ vertical profiles on the land between 60°N and 55°S can be well modelled
292 using Gaussian function (R² higher than 0.90) (**Fig. 1**). Previous studies also found
293 high accuracy using the Gaussian function to simulate the NH₃ vertical profiles in
294 China and globally (Whitburn et al., 2016;Liu et al., 2017b).

295 **Validation of satellite-derived surface NH₃ concentrations**

296 NH₃ vertical profiles were used to convert IASI NH₃ columns to surface NH₃
297 concentrations. **Fig. 2** shows the IASI-derived global surface NH₃ concentrations on
298 the land at 0.25° latitude × 0.25° longitude grids in 2014. IASI-derived surface NH₃
299 concentrations capture the general spatial pattern of surface NH₃ concentrations fairly
300 well in 2014 in regions with relatively intensive monitoring sites (R²=0.76 and
301 RMSE=1.50 μg N m⁻³ in **Fig. 2 and Fig. 3**). Overall, 72.85% of observations
302 (including China, the US and Europe) were within a factor of two of the
303 satellite-derived surface NH₃ concentrations. In China, there is approximately 71.43%
304 and 77.27% of observations were within a factor of two of the satellite-derived
305 surface NH₃ concentrations in urban and rural land uses, respectively. There is no big
306 difference in the accuracy of satellite-derived surface NH₃ concentrations between
307 urban and rural land uses. In the US, the monitoring sites were generally distributed at
308 rural sites (<http://www.radiello.com>) (Li et al., 2016), and, in Europe, there is no
309 information to indicate the land use of each site (<https://projects.nilu.no//ccc/>)
310 (Tørseth et al., 2012a). The overall mean of satellite-derived surface NH₃
311 concentrations in 2014 at the measured sites was 2.52 μg N m⁻³ and was close to the
312 average of measured surface NH₃ concentrations (2.51 μg N m⁻³) in 2014.

313 IASI-derived surface NH_3 concentrations gained higher consistency with the
314 ground-based measurements in China ($R^2=0.71$ and $\text{RMSE}=2.6 \mu\text{g N m}^{-3}$ for 43 sites)
315 than the US ($R^2=0.45$ and $\text{RMSE}=0.76 \mu\text{g N m}^{-3}$ for 67 sites) and Europe ($R^2=0.45$
316 and $\text{RMSE}=0.86 \mu\text{g N m}^{-3}$ for 43 sites) at a yearly scale. This might be due to the fact
317 that for high concentrations in a region (associated with high thermal contrast) can be
318 more reliably detected by IASI (Van Damme et al., 2014a). The accuracy of
319 IASI-retrieved surface NH_3 concentrations in different regions is highly linked with
320 the thermal contrast (TC) and atmosphere NH_3 abundance (Whitburn et al., 2016).
321 The lowest uncertainties occur when high columns and high TC coincide. In case
322 either of them decrease, the uncertainty will gradually increase. In case both the TC
323 and column are low, all sensitivity to NH_3 is lost. When high TC and high NH_3
324 columns (high HRI) occurs, the major contribution to the uncertainty results from the
325 thickness of the NH_3 layer, the surface temperature as well as the temperature profile
326 (Whitburn et al., 2016). The simulation of NH_3 mixing from GEOS-Chem may also
327 have different accuracy in different regions, and thus can cause uncertainty to the
328 different accuracy of IASI-retrieved surface NH_3 concentrations in different regions.
329 Notably, we compared the surface NH_3 concentrations at the monitoring stations with
330 the grid values of satellite-derived estimates directly. This point-to-grid verification
331 strategy may cause uncertainty since the monitoring site location may not be
332 representative of a given grid cell for an average retrieved value. The satellite-derived
333 NH_3 has a detection limit of $0.0025 \mu\text{g N m}^{-3}$ (2.5 ppb) (Graaf et al., 2018; Van
334 Damme et al., 2014a). Similarly, we also compared the surface NH_3 concentrations (at
335 the first layer) simulated by GEOS-Chem with the monitoring results ($R^2=0.54$ and
336 $\text{RMSE}=2.14 \mu\text{g N m}^{-3}$ in **Fig. 3**). In general, IASI-derived surface NH_3 concentrations
337 had better consistency with the ground-based measurements than those from
338 GEOS-Chem over China, the US and Europe. The relatively low accuracy from
339 GEOS-Chem was likely due to the coarse model resolutions as well as the poor
340 spatiotemporal representations of NH_3 emissions, as suggested by a previous study
341 (Zhang et al., 2018).
342 A known limitation of IASI NH_3 retrievals is lack of the vertical profile information.

343 A previous study (Van Damme et al., 2014a) used fixed profiles on the land to convert
344 the IASI NH₃ columns to surface NH₃ concentrations. Using the fixed profiles can
345 cause large uncertainties for estimating surface NH₃ concentrations. In this work, we
346 utilized the advantages of CTMs and considered the spatial variability of the vertical
347 profiles, and proves that IASI NH₃ columns are powerful to predict the surface NH₃
348 concentrations combining the vertical profiles simulated by Gaussian function.
349 Through the Gaussian simulation of NH₃ vertical profiles, we are able to evaluate the
350 sensitive regions of surface NH₃ concentrations with respect to different heights. **Fig.**
351 **S5** shows the spatial distribution of the difference of NH₃ concentrations between
352 40m and 60m (about the middle height of the first layer in GEOS-Chem). In general,
353 in strong NH₃ emission regions, there is a relatively large difference in surface NH₃
354 concentrations such as, for instance, in eastern China and northwestern India (can be
355 up to 3 μg N m⁻³); subsequently, a middle difference (2-3 μg N m⁻³) occurs in eastern
356 and middle China, northern India and northern Italy. Except above mentioned regions,
357 the difference of NH₃ concentrations between 40m and 60m is generally lower 0.5 μg
358 N m⁻³.

359 **Spatial distributions of satellite-derived surface NH₃ concentrations**

360 **Fig. 4** shows the spatial distributions of surface NH₃ concentrations in China, US and
361 Europe in 2014. The overall mean surface NH₃ concentrations over China were 2.38
362 μg N m⁻³, with the range of 0.22-13.11 μg N m⁻³. We found large areas in [eastern](#)
363 [China \(109-122° E, 28-41° N\)](#), Sichuan Basin, [Hubei \(including Wuhan, Xiangyang](#)
364 [and Yichang\)](#), [Shaanxi \(including Xi'an, Baoji, Hanzhong, Weinan\)](#), [Gansu \(Lanzhou](#)
365 [and its surrounding areas\)](#), [Shanxi \(including Yuncheng and Changzhi\)](#) and
366 northwestern Xinjiang with surface NH₃ concentrations greater than 8 μg N m⁻³ y⁻¹,
367 which were in agreement with the spatial distributions of the croplands in China (**Fig.**
368 **S6**). It is not surprising that high surface NH₃ concentrations occurred in eastern
369 China and Sichuan Basin because the major Chinese croplands are distributed there,
370 as the major source of NH₃ emissions with frequent N fertilizer applications. [In](#)
371 [addition, N manure is another major source of NH₃ emissions in China, and the](#)

372 percentage of N manure to NH₃ emissions exceeds 50% (Kang et al., 2016). Overall,
373 there was a significant linear correlation between surface NH₃ concentration and N
374 fertilization plus N manure in China ($R^2=0.69$, $p=0.000$ in **Fig. 5**). The hotspots also
375 occurred in northwestern Xinjiang surrounding the cropland areas, which may be
376 related to the dry climate that can maintain NH₃ in the gaseous state for a longer time,
377 providing climate conditions for the long distance transmission of NH₃. Recent
378 national measurement work (Pan et al., 2018) also revealed high surface NH₃
379 concentrations in northwestern Xinjiang, confirming the rationality of the
380 IASI-derived estimates.

381 In the US, the overall mean surface NH₃ concentrations were $1.52 \mu\text{g N m}^{-3} \text{ y}^{-1}$, with
382 the range of $0.14\text{-}10.60 \mu\text{g N m}^{-3}$. The surface NH₃ hotspots were generally
383 distributed in the croplands in the central and eastern US (such as Ohio, Illinois, South
384 Dakota, Nebraska, Kansas, Minnesota and North Dakota), as well as in some small
385 areas in western coastal regions (such as California and Washington). In particular, the
386 San Joaquin Valley (SJV) in California (an agricultural land) had the highest surface
387 NH₃ concentrations greater than $4 \mu\text{g N m}^{-3}$. The NH₃ source in SJV was from
388 livestock and mineral N fertilizer, which accounted for 74% and 16% of total NH₃
389 emissions, respectively (Simon et al., 2008). Except the SJV in California, the annual
390 surface NH₃ concentrations in the croplands were mostly within the range of $1\text{-}3 \mu\text{g N}$
391 m^{-3} , which were much lower than those in eastern China (mostly within the range of
392 $4\text{-}10 \mu\text{g N m}^{-3}$). Compared with the spatial distribution of N fertilization plus N
393 manure, the hotspots of surface NH₃ concentration can basically reflect the
394 distribution of high N fertilization ($R^2=0.37$, $p=0.000$ in **Fig 4 and Fig. 5**).

395 In Europe, the overall mean surface NH₃ concentrations were $1.8 \mu\text{g N m}^{-3}$, with the
396 range of $0.04\text{-}9.49 \mu\text{g N m}^{-3}$. High surface NH₃ concentrations were distributed
397 widespread in the croplands, especially in the western regions with values greater than
398 $4 \mu\text{g N m}^{-3}$, such as Northern Italy (Milan and its surrounding areas), Switzerland,
399 central and southern Germany, Eastern France (Paris and its surrounding areas) and
400 Poland. According to Emissions Database for Global Atmospheric Research
401 (EDGAR), N manure and N fertilization accounts for 53% and 43% of the NH₃

402 emissions in western Europe. Overall, there was also a significant linear correlation
403 between surface NH₃ concentration and N fertilization plus N manure (R²=0.39,
404 p=0.000) in Europe, reflecting the importance of N fertilization on surface NH₃
405 concentration.

406 NH₃ is the most abundant alkaline gas in the atmosphere, and has implications to
407 neutralize acidic species (such as H₂SO₄ and HNO₃) to form ammonium salts (such as
408 (NH₄)₂SO₄ and NH₄NO₃). Ammonium salts are the important inorganic N
409 components in PM_{2.5}, which can reduce regional visibility and contribute to human
410 disease burden (Van et al., 2015; Yu et al., 2007). Comparing surface NH₃
411 concentrations with PM_{2.5} can benefit the understanding of the sources and the
412 mixture of air pollution. The spatial distribution of satellite-derived PM_{2.5} (dust and
413 sea-salt removed) in 2014 (**Fig. S7**) gained from a previous study (Van et al., 2016)
414 was compared with the satellite-derived surface NH₃ concentrations in 2014. On the
415 other hand, NO₂ is also an important precursor of nitrate salts in PM_{2.5}. We also
416 included the satellite-derived surface NO₂ concentrations (**Fig. S7**) from a previous
417 study (Geddes et al., 2016) to compare with surface NH₃ and PM_{2.5} concentrations.

418 The hotspots of surface NH₃ concentrations were highly linked with the hotspots of
419 PM_{2.5}. The most severe pollution occurred in the eastern China with annual average
420 PM_{2.5} exceeding 50 µg m⁻³ (much higher than 35 µg m⁻³ as the level 2 annual PM_{2.5}
421 standard set by World Health Organization Air Quality Interim Target-1), and annual
422 average surface NH₃ and NO₂ concentrations greater than 8 µg N m⁻³ and 4 µg N m⁻³,
423 respectively. A previous study (Xu et al., 2017) reported that the secondary inorganic
424 aerosols of NH₄⁺ and NO₃⁻ can account for 65% of PM_{2.5} based on the measurements
425 in three sites in Beijing. NH₃ and NO₂ are the most important precursors of nitrate
426 salts and ammonium salts, and certainly contribute to the severe pollution in the
427 eastern China. The second severe pollution occurred in the northern India with annual
428 average PM_{2.5} and surface NH₃ concentrations exceeding 40 µg m⁻³ and 4 µg N m⁻³
429 respectively (surface NO₂ concentrations less than 1 µg N m⁻³). The major source of
430 NH₃ in northern India was from agricultural activities and livestock waste
431 management (Warner et al., 2016). The hotspots of surface NH₃ concentrations in the

432 central and eastern US were highly related to the hotspots of PM_{2.5}. The annual
433 average PM_{2.5} is less than 10 µg m⁻³ (the first level set by World Health Organization)
434 in the most areas of the US, and only small areas had PM_{2.5} greater than 10 µg m⁻³.
435 Similarly, in western Europe, the hotspots of high surface NH₃ and NO₂
436 concentrations (greater than 3 µg N m⁻³) were consistent with the hotspots of PM_{2.5}
437 (greater than 20 µg m⁻³).

438 **Seasonal variations of satellite-derived surface NH₃ concentrations**

439 To investigate the seasonal variations of surface NH₃ concentrations, we took the
440 monthly surface NH₃ concentrations in 2014 as a case study (**Fig. 6**), and analyzed the
441 seasonal surface NH₃ concentrations in hotspot regions including East China (ECH),
442 Sichuan and Chongqing (SCH), Guangdong (GD), Northeast India (NEI), East US
443 (EUS) and West Europe (WEU) (**Fig. 7**).

444 Seasonal mean IASI-derived surface NH₃ concentrations vary by more than 2 orders
445 of magnitude in hotspot regions, such as the eastern China and eastern US. In China,
446 high surface NH₃ concentrations occurred in spring (March, April and May) and
447 summer (June, July and August) in East China (ECH), Sichuan and Chongqing (SCH),
448 Guangdong (GD). This may be due to two major reasons. First, the timing of the
449 mineral N fertilizer or manure application occurred in summer or spring in the
450 croplands (Paulot et al., 2014). A previous study (Huang et al., 2012) also suggested a
451 summer peak in NH₃ emissions in China, which was consistent with the summer peak
452 in surface NH₃ concentrations. Second, the temperature in warm months is highest in
453 one year, which favors the volatilization of ammonium ($\text{NH}_4^+ + \text{OH}^- \rightarrow \text{NH}_3 + \text{H}_2\text{O}$).
454 [Notably, there is a difference in the seasonal variations of surface NH₃ concentrations](#)
455 [between ECH \(peaking in June and July\) and GD \(peaking in March\), which was](#)
456 [likely related to different crop planting, N fertilization time as well as meteorological](#)
457 [factors \(Van Damme et al., 2015; Shen et al., 2009; Van Damme et al., 2014a\).](#) In the
458 eastern US (EUS), high surface NH₃ concentrations appeared in warm months (from
459 March to August, **Fig. 7**) with the maximum in May due to higher temperature and
460 emissions in vast croplands, where the agricultural mineral N fertilizers dominate the

461 NH₃ emissions. A previous study also implied a spring peak in NH₃ emissions in the
462 eastern US (Gilliland et al., 2006). Since the spatial patterns of high surface NH₃
463 concentrations are highly linked with the spatial distributions of croplands, seasonal
464 surface NH₃ concentrations mainly reflects the timing of N fertilizers in the croplands.
465 In western Europe, surface NH₃ concentrations is low in January and February, rising
466 in March and reaching its maximum, keeping high from March to June, then declining
467 from June to December (**Fig. 7**). High NH₃ concentrations appeared from March to
468 June, mainly affected by higher temperature and frequent N fertilization (Van Damme
469 et al., 2014b;Paulot et al., 2014;Van Damme et al., 2015;Whitburn et al., 2015).

470 To identify the major regions of biomass burning that may affect the spatial
471 distribution of surface NH₃ concentrations, we used the fire products from the
472 moderate resolution imaging spectroradiometer (MODIS) on board the NASA Aqua
473 and Terra. The MODIS climate modeling grid (CMG) global monthly fire location
474 product (level 2, collection 6) developed by the University of Maryland included
475 geographic location of fire, raw count of fire pixels and mean fire radiative power
476 (Giglio et al., 2015). We used the Aqua and Terra CMG fire products on a monthly
477 scale at a spatial resolution of 0.5 °latitude × 0.5 °longitude in 2014, and the fire pixel
478 counts were used to identify the hotspot regions of biomass burning. In the major
479 hotspots with frequent fires (mostly in the southern hemisphere), the biomass burning
480 controlled the seasonal surface NH₃ concentrations (**Fig. S8 and Fig. S9**), such as, for
481 instance, Africa north of equator, Africa south of equator and central South America.
482 Apart from the large areas with frequent fires in the southern hemisphere, we also
483 demonstrated the relationship of biomass burning and surface NH₃ concentrations in
484 China, US and Europe, and selected six typical regions in China (CH1 and CH2), US
485 (US1 and US2) and Europe (EU1 and EU2) (**Fig. 8**) to analyze the monthly variations
486 of fire counts and surface NH₃ concentrations.

487 In China, the first region (CH1) covers the major cropland areas in northern China
488 including Shandong, Henan and and northern Jiangsu Provinces. The fires counts
489 were mainly from the crop straw burning, which contributes large to surface NH₃
490 concentrations. Both surface NH₃ concentrations and fire counts were found in June

491 likely related to the crop straw burning in this agricultural regions. Notably, despite a
492 decline in fire counts in July, the surface NH_3 concentrations in July did not decrease,
493 probably due to mineral N fertilization for new planted crops (CH1 is typical for
494 spring and summer corn rotations) as well as the high temperature favoring NH_3
495 volatilization in July. The second region (CH2) is typical for the rice cultivation area
496 in the southern China, where the rice was normally planted in June or July with
497 frequent mineral N fertilization. Thus, the highest surface NH_3 concentrations
498 occurred in June and July. This region is also typical for the winter wheat and summer
499 rice rotations, and the wheat is normally harvested from May to July, which can lead
500 to frequent fire counts there. Despite the more frequent fires in the second region than
501 the first region, the surface NH_3 concentrations in CH2 were much lower than those in
502 CH1. This may be due to the wetter climate and more frequent precipitation events in
503 CH2 than in CH1, resulting in higher scavenging of surface NH_3 concentrations into
504 water.

505 US1 is a region typical for forest land in the US, and the fire counts are certainly from
506 the forest fires or anthropogenic biomass burning. The monthly variations of surface
507 NH_3 concentrations were consistent with the monthly variations of MODIS fire counts,
508 which peaked in August with high temperature. Instead, US2 is a region typical for
509 mixed agricultural and forest lands, which can be influenced by both potential mineral
510 N fertilization and anthropogenic biomass burning or forest fires. It is clear to see that
511 there is a peak in surface NH_3 concentrations in October resulting from the biomass
512 burning because of the same peak in fire counts in October. However, there is also an
513 apparent peak in surface NH_3 concentrations in May, which may result from the
514 mineral N fertilization in this region. In Europe, the selected two regions of EU1 and
515 EU2 are mainly covered by crops, vegetables as well as forests. For EU2, the monthly
516 variations of surface NH_3 concentrations were consistent with the monthly variations
517 of MODIS fire counts, which peaked in August with high temperature, implying that
518 the biomass burning may control the seasonal surface NH_3 concentrations. For EU1,
519 there were two peaks of surface NH_3 concentrations including April and August. The
520 August peak can be related to the biomass burning because of the high fire counts,

521 while the April peak may be related to the agricultural fertilizations for the spring
522 crops.

523 **Trends in surface NH₃ concentrations in China, the US and Europe**

524 Time series of nine years' (2008-2016) IASI-derived surface NH₃ concentrations have
525 been fitted using the linear regression method (Geddes et al., 2016;Richter et al., 2005)
526 for all grids on the land. The annual trend (the slope of the linear regression model) is
527 shown in **Fig. 9**. A significant increase rate of surface NH₃ concentrations (>0.2 μg N
528 m⁻³ y⁻¹) appeared in eastern China, and a middle positive trend (0.1-0.2 μg N m⁻³ y⁻¹)
529 occurred in northern Xinjiang, corresponding to its frequent agricultural activities for
530 fertilized crops and dry climate (Warner et al., 2017;Liu et al., 2017b;Xu et al.,
531 2015;Huang et al., 2012). The large increase in eastern China was consistent with the
532 results revealed by AIRS NH₃ data (Warner et al., 2017). [The increase of surface NH₃
533 concentrations in eastern China was consistent with the trend of NH₃ emission
534 estimates by a recent study \(Zhang et al., 2017b\)](#). China's NH₃ emissions increased
535 significantly from 2008 to 2015, with an increase rate of 1.9% y⁻¹, which was mainly
536 driven by eastern China (Zhang et al., 2017b). [Approximately 85% of the inter-annual
537 variations was due to the changes of human activities, and the remaining 15% resulted
538 from air temperature changes. Agricultural activities is the main drive of NH₃
539 emission increase, of which 43.1% and 36.4% were contributed by livestock manure
540 and fertilizer application \(Zhang et al., 2017b\)](#). In addition, the increase in surface
541 NH₃ concentrations in eastern China may be also linked with the decreased NH₃
542 removal due to the decline in acidic gases (NO₂ and SO₂) (Liu et al., 2017a;Xia et al.,
543 2016). NH₃ can react with nitric acid and sulfuric acid to form ammonia sulfate and
544 ammonia nitrate aerosols. The reduction of acidic gases leads to the reduction of NH₃
545 conversion to ammonia salts in the atmosphere, which may lead to the increase of
546 NH₃ in the atmosphere (Liu et al., 2017a;Li et al., 2017b). China's SO₂ emissions
547 decreased by about 60% in 2008-2016, which [led](#) to a 50% decrease in surface SO₂
548 concentrations simulated by WRF model, and then resulted in a 30% increase in
549 surface NH₃ concentrations (Liu et al., 2018).

550 In the US, the NH₃ increase was found in agricultural regions in middle and eastern
551 regions with an annual increase rate of lower than 0.10 μg N m⁻³ y⁻¹, which was
552 consistent with the results of AIRS NH₃ data for a longer time period (2003-2016)
553 (Warner et al., 2017), while we concerned the timespan of 2008-2016 from IASI
554 retrievals. Based on the simulation data of CMAQ model, it is also found that NH₃
555 increased significantly in the eastern US from 1990 to 2010, which is inconsistent
556 with the significant downward trend of NO_x emissions (Zhang et al., 2018). This
557 inconsistency between NH₃ and NO_x trends in the US was mainly due to different
558 emission control policies. Over the past two decades, due to the implementation of
559 effective regulations and emission reduction measures for NO_x, the NO_x emission in
560 the US decreased by nearly 41% between 1990 and 2010 (Hand et al., 2014).
561 However, this NH₃ increase in eastern US is likely due to the lack of NH₃ emission
562 control policy as well as the decreased NH₃ removal due to the decline in acidic gases
563 (NO₂ and SO₂) (Warner et al., 2017; Li et al., 2016). As NH₃ is an uncontrolled gas in
564 the US, NH₃ emissions have continuously increased since 1990, and by 2003 NH₃
565 emissions had begun to dominate the inorganic N emissions (NO_x plus NH₃) (Zhang
566 et al., 2018). For the western Europe, the trend was close to 0 in most regions
567 although we can observe the NH₃ increase in many points with small positive trend of
568 lower than 0.1 μg N m⁻³ y⁻¹. Compared with the trend of surface NH₃ concentrations
569 in China and the US, the change of surface NH₃ concentrations in western Europe is
570 more stable, which may be related to the mature NH₃ reduction policies and measures
571 in Europe. Since 1990, Europe has implemented a series of agricultural NH₃ emission
572 reduction measures, and NH₃ emissions decreased by about 29% between 1990 and
573 2009 (Tørseth et al., 2012b). For example, due to serious N eutrophication, the
574 Netherlands has taken measures to reduce NH₃ emissions by nearly two times in the
575 past 20 years, while maintaining a high level of food production (Dentener et al.,
576 2006). The N fertilizer use in Europe has decreased widespread according to the data
577 from the World Bank (<http://data.worldbank.org/indicator/AG.CON.FERT.ZS>) with
578 an annual decrease of -8.84~-17.7 kg ha⁻¹ y⁻¹ in fertilizer use in Europe (Warner et al.,
579 2017).

580 **Conclusions**

581 The IASI-derived global surface NH₃ concentrations during 2008-2016 were inferred
582 based on IASI NH₃ column measurements as well as NH₃ vertical profiles from the
583 GEOS-Chem in this study. Global NH₃ vertical profiles on the land from the
584 GEOS-Chem can be well modelled by the Gaussian function between 60 °N and 55 °
585 S with R² higher than 0.90. The IASI-derived surface NH₃ concentrations were
586 compared to the in situ measurements over China, the US and Europe. One of the
587 major findings is that a relatively high predictive power for annual surface NH₃
588 concentrations was achieved through converting IASI NH₃ columns using modelled
589 NH₃ vertical profiles, and the validation with the ground-based measurements shows
590 that IASI-derived surface NH₃ concentrations had higher accuracy in China than the
591 US and Europe. High surface NH₃ concentrations were found in the croplands in
592 China, US and Europe, and surface NH₃ concentrations in the croplands in China
593 were approximately double than those in the US and Europe. Seasonal mean
594 IASI-derived surface NH₃ concentrations vary by more than 2 orders of magnitude in
595 hotspot regions, such as the eastern China and eastern US. The linear trend analysis
596 shows that a significant positive increase rate of above 0.2 μg N m⁻³ y⁻¹ appeared in
597 the eastern China during 2008-2016, and a middle increase trend (0.1-0.2 μg N m⁻³ y⁻¹)
598 occurred in northern Xinjiang Province. In the US, the NH₃ increase was found in
599 agricultural regions in middle and eastern regions with an annual increase rate of
600 lower than 0.10 μg N m⁻³ y⁻¹.

601 **Author contributions**

602 LL and XZ designed the research; WX and XL's group conducted the field work in
603 China; LL prepared IASI NH₃ products; LL and AW conducted model simulations;
604 LL, WX, LZ, XW and ZW performed the data analysis and prepared the figures; LL,
605 AW and XZ wrote the paper, and all coauthors contribute to the revision.

606 **Acknowledgements**

607 We acknowledge the free use of IASI NH₃ data from the Atmospheric Spectroscopy
608 Group at Université libre de Bruxelles (ULB). We thank Dr. Jeffrey A. Geddes for the
609 help of using the GEOS-Chem in this work. This study is supported by the National
610 Natural Science Foundation of China (No. 41471343, 41425007 and 41101315) and
611 Doctoral Research Innovation Fund (2016CL07) as well as the Chinese National
612 Programs on Heavy Air Pollution Mechanisms and Enhanced Prevention Measures
613 (Project No. 8 in the 2nd Special Program).

614 **Data availability**

615 The IASI NH₃ satellite datasets are available at: <http://iasi.aeris-data.fr/NH3>. The
616 ground-based NH₃ measurements in Chinese Nationwide Nitrogen Deposition
617 Monitoring Network (NNDMN) can be requested from Prof. Xuejun Liu in China
618 Agricultural University. The ground-based NH₃ measurements from the AMoN-US
619 can be downloaded from the website: <http://nadp.sws.uiuc.edu/AMoN/>. The
620 ground-based NH₃ measurements from the EMEP network can be gained from
621 <https://www.nilu.no/projects/ccc/emepdata.html>. The IASI-derived surface NH₃ used
622 in this study are available from the corresponding author upon request.

623 **Notes**

624 The authors declare that they have no conflict of interest.

Fig. 4 Spatial distribution of IASI-derived surface NH₃ concentrations, and N fertilizer plus N manure in China, Europe and US.

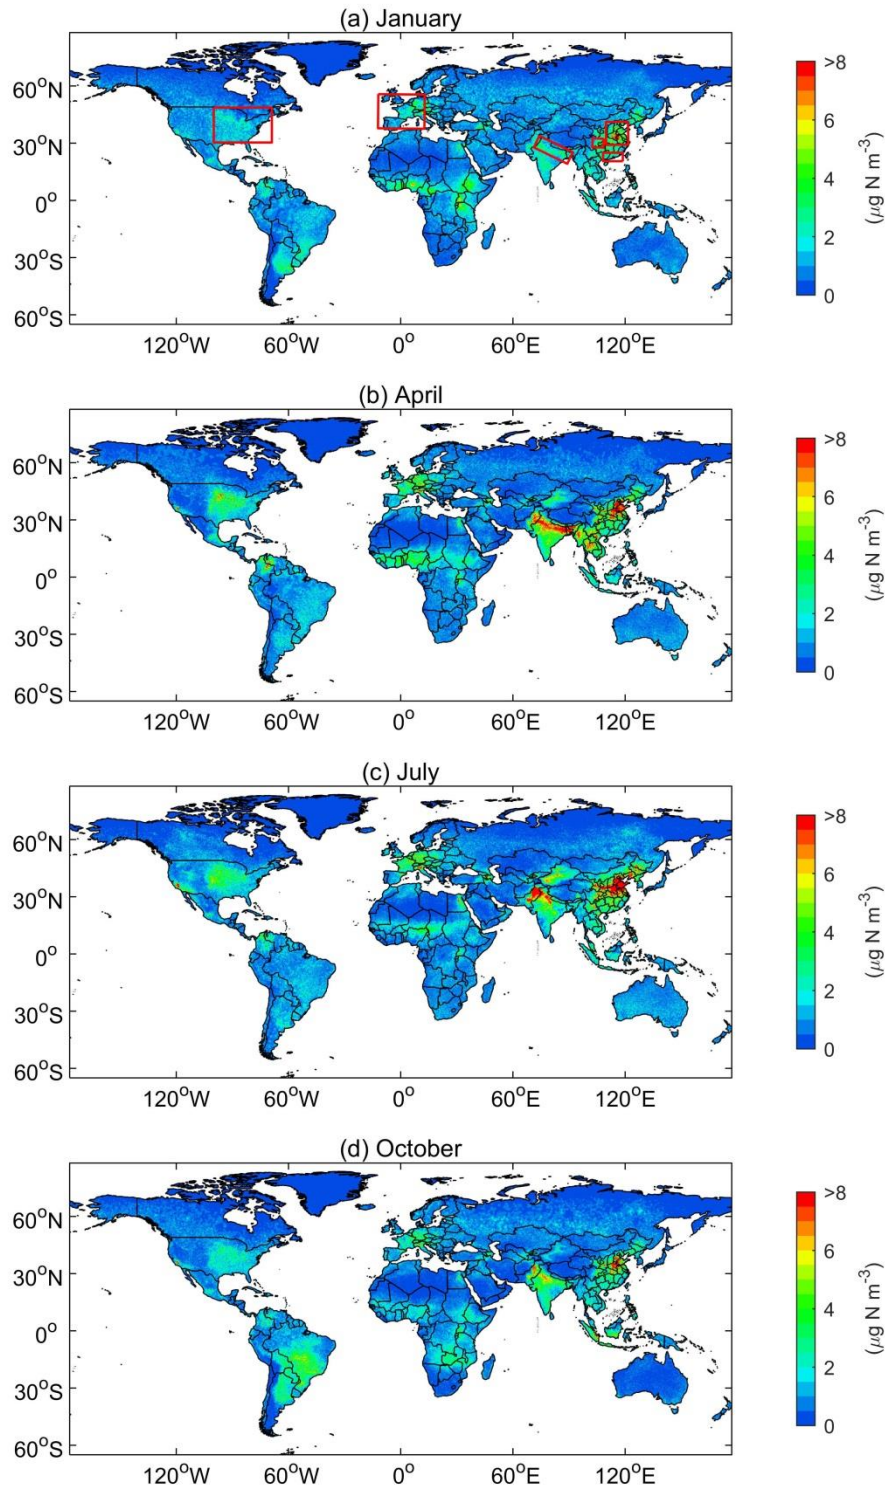

953

954

955

956 **Fig. 5** Comparison of satellite-derived surface NH₃ concentrations and N fertilizer plus N manure in
957 China, US and Europe. The spatial resolution of satellite-derived surface NH₃ concentrations and N
958 fertilizer plus N manure is 0.25° and 0.5°, respectively. We firstly resampled the satellite-derived
959 surface NH₃ concentrations to 0.5° grids, and then compared it with N fertilizer plus N manure by each
960 grid cell. We obtained the N fertilizer and N manure data produced from McGill University (Potter et
961 al., 2010).
