17 Abstract

18 Atmospheric organic nitrate (ON) is thought to play a crucial role in the formation potential of
19 ozone and aerosol, which are the leading air pollutants of concern across the world. Limited fundamental
20 knowledge and understanding of the life cycles of ON currently hinders the ability to quantitatively assess
21 its impacts on the formation of these pollutants. Although hydrolysis is currently considered as an important
22 loss mechanism of ON based on prior field measurement studies, this process for atmospherically relevant
23 ON has not been well constrained by fundamental laboratory studies. In this comprehensive study, we
24 investigated the chemical composition and hydrolysis process of particulate ON (p ON) formed from the
25 oxidation of α -pinene and β -pinene by hydroxyl and nitrate radicals. For p ON that undergoes hydrolysis,
26 the hydrolysis lifetime is determined to be no more than 30 min for all systems explored. This is
27 significantly shorter than those reported in previous chamber studies (i.e., 3-6 h) but is consistent with the
28 reported lifetime from bulk solution measurement studies (i.e., 0.02-8.8 h). The discrepancy appears to stem
29 from the choice of proxy used to estimate the hydrolysis lifetime. The measured hydrolyzable fractions of
30 p ON (F_H) in the α -pinene+OH, β -pinene+OH, α -pinene+NO₃, and β -pinene+NO₃ systems are 23-32, 27-
31 34, 9-17, and 9-15 %, respectively. While a very low F_H for the nitrate radical oxidation system is expected
32 based on prior studies, F_H for the hydroxyl radical oxidation system is surprisingly lower than predicted in
33 past studies. Overall, the hydrolysis lifetime as well as F_H obtained in this study serve as experimentally
34 constrained parameters that are required in regional and global chemical transport models to accurately
35 evaluate the impacts of ON on nitrogen budget and formation of ozone and aerosol.

36

37 1. Introduction

38 The oxidation of biogenic volatile organic compounds (BVOC) by ozone (O₃), hydroxyl radicals
39 and nitrate radicals is a major source of secondary organic aerosol (SOA) globally (Kanakidou et al., 2005;
40 Goldstein and Galbally, 2007; Spracklen et al., 2011). Many studies have pointed to the synergistic effects
41 of anthropogenic emissions on biogenic SOA formation in the atmosphere (Weber et al., 2007; Carlton et
42 al., 2010; Hoyle et al., 2011; Shilling et al., 2013; Xu et al., 2015a; Shrivastava et al., 2019). The oxidation
43 of BVOC in environments with anthropogenic NO_x emissions is an important mechanism for coupled
44 biogenic-anthropogenic interactions. In the presence of NO_x, the oxidation of BVOC can lead to the
45 formation of organic nitrate (ON), a large component of reactive oxidized nitrogen. Results from ambient
46 field measurements have revealed the ubiquitous presence of particulate ON (pON), where it contributes to
47 a large fraction of submicron organic aerosol at different sites worldwide (Fry et al., 2013; Xu et al., 2015b;
48 Liu et al., 2012a; Rollins et al., 2012; Rollins et al., 2013; Lee et al., 2016; Kiendler-Scharr et al., 2016; Ng
49 et al., 2017). These findings highlights the importance to understand the formation and fates of ON to
50 accurately evaluate its roles in NO_x recycling, O₃, and SOA formation.

51 Monoterpenes (C₁₀H₁₆) is a major class of BVOC, with annual emissions of 157-177 Tg C yr⁻¹
52 (Guenther et al., 2012). Laboratory studies have demonstrated that the nitrate radical oxidation of
53 monoterpenes leads to a substantial formation of ON and SOA, with ON yields up to ~70% (Wangberg et
54 al., 1997; Berndt and Boge, 1997; Griffin et al., 1999; Hallquist et al., 1999; Spittler et al., 2006; Fry et al.,
55 2009; Fry et al., 2014; Boyd et al., 2015; Nah et al., 2016; Boyd et al., 2017; Slade et al., 2017; Clafin and
56 Ziemann, 2018). For photooxidation of monoterpenes in the presence of NO_x, ON yields as high as 26%
57 have been reported for α-pinene (Noziere et al., 1999; Aschmann et al., 2002; Rindelaub et al., 2015).
58 Monoterpene emissions do not depend strongly on light and typically continue at night, making them
59 important ON and SOA precursors at any times of the day (daytime and nighttime) and throughout the year
60 (different seasons). It has been shown that monoterpene-derived ON is prevalent in areas where there are
61 substantial biogenic-anthropogenic interactions and oxidation of monoterpenes contributes to a large

62 fraction of SOA observed in the Southeastern U.S. (Xu et al., 2015a; Xu et al., 2015b; Lee et al., 2016;
63 Zhang et al., 2018; Xu et al., 2018a).

64 One of the largest uncertainties in our understanding of monoterpene ON chemistry is the extent to
65 which ON act as a permanent sink versus temporary reservoir of NO_x (Takeuchi and Ng, 2018). This would
66 depend on the fates of ON as they can either retain or release NO_x upon further reactions. Once formed,
67 gas-phase ON can undergo photolysis or hydroxyl radical oxidation to release NO_x or partition into the
68 particle phase. _pON in turn can undergo further chemistry to release NO_x or hydrolyze in the particle phase
69 to form nitric acid (HNO₃). Further, ON and HNO₃ can be removed via dry and wet deposition. One
70 important reaction of ON in the particle phase is hydrolysis in the presence of aerosol water, which is a
71 mechanism for NO_x loss (Day et al., 2010; Russell et al., 2011). Studies with bulk solutions showed that
72 particle-phase hydrolysis of tertiary nitrate is fast with a lifetime of minutes, while primary and secondary
73 nitrate is stable (Darer et al., 2011; Hu et al., 2011). However, the hydrolysis of _pON in aerosol water is
74 largely unconstrained. Results from field and modeling studies suggested a _pON lifetime of a few hours
75 (Pye et al., 2015; Lee et al., 2016; Fisher et al., 2016; Zare et al., 2018). A few recent laboratory chamber
76 studies elicited a complex picture where _pON formed from photochemical oxidation and nitrate radical
77 oxidation of monoterpenes appear to experience different magnitudes of hydrolysis (Boyd et al., 2015;
78 Rindelaub et al., 2015; Bean and Hildebrandt Ruiz, 2016; Boyd et al., 2017), likely due to the difference in
79 the relative amount of primary, secondary, and tertiary nitrate in these oxidation systems. Overall, there are
80 very limited studies on the further evolutions of ON produced from the oxidation of monoterpenes.

81 Here, we present results from a laboratory chamber study on the chemical composition and
82 hydrolysis process of _pON formed from oxidation of α -pinene and β -pinene by hydroxyl and nitrate radicals.
83 Specifically, we report the hydrolysis lifetimes and the fraction of hydrolyzable _pON formed in the systems
84 examined in this study. This comprehensive chamber study on the hydrolysis of _pON produced from various
85 oxidation pathways of monoterpenes and peroxy radical (RO₂) fates provides the fundamental data to better
86 constrain the role of hydrolysis in modulating _pON concentrations and lifetimes in the atmosphere, their
87 potential as a NO_x loss pathway, and their impacts on overall nitrogen budget, O₃ and SOA formation.

88

89 **2. Methods**90 2.1. Chamber experiment design and procedure

91 A series of chamber experiments were performed in the Georgia Tech Environmental Chamber
92 facility (Boyd et al., 2015) housing two 12 m³ Teflon reactors. Precursor volatile organic compounds (VOC)
93 were α -pinene (99 %, Sigma-Aldrich) and β -pinene (99 %, Sigma-Aldrich) and the oxidation conditions of
94 interest were hydroxyl and nitrate radical oxidation, which were represented as “daytime” and “nighttime”
95 experiments, respectively. Specifically, four different systems of VOC and oxidation conditions were
96 studied: α -pinene+OH, β -pinene+OH, α -pinene+NO₃, and β -pinene+NO₃. In order to infer the hydrolysis
97 process, experiments were performed under low RH (i.e., ~5 %) or high RH (i.e., ~50-70 %) conditions and
98 with effloresced or deliquesced seed particles for the same initial concentrations of precursor VOC and
99 oxidant precursors. Temperature in the reactors was kept at room temperature (22-25°C). Experimental
100 conditions are summarized in Table 1.

101 Prior to every experiment, the reactor was flushed with zero air (AADCO, 747-14) for at least a
102 day. A typical experiment began with the injection of seed aerosol into the reactor by atomizing dilute
103 ammonium sulfate (AS; 0.015 M) or sulfuric acid + magnesium sulfate (SA+MS; 0.01 + 0.005 M) aqueous
104 solution. The seed aerosol was either directly atomized into the reactor or passed through a dryer before
105 entering the reactor. The difference between efflorescence RH (~35 %) and deliquescence RH (~80 %) for
106 AS aerosol is fairly large (Seinfeld and Pandis, 2016). Taking advantage of this property, it is possible to
107 vary the amount of water in aerosol under the same RH in the reactor. Initial seed number and volume
108 concentrations upon atomization for 20 min were approximately $2 \times 10^4 \text{ cm}^{-3}$ and $2 \times 10^{10} \text{ nm}^3 \text{ cm}^{-3}$,
109 respectively. A known amount of precursor VOC in the liquid form was transferred into a glass bulb, which
110 was then evaporated and carried into the reactor by flowing zero air at 5 L min^{-1} through the bulb. Although
111 the measurement of the precursor VOC concentration was not available for all experiments, the target and
112 measured concentrations in the experiments when the measurements were available were consistent.

113 For “daytime” experiments, an oxidant precursor (i.e., H_2O_2) was introduced to the reactor in the
114 same manner as VOC except that the glass bulb was gently heated by a heat gun to help evaporate faster.
115 During the injection of H_2O_2 , a desired amount of NO was introduced into the reactor from a cylinder
116 containing 500 ppm NO (Matheson). For Exp. 3-5, 5 ppm NO at 5 L min^{-1} was continuously injected to the
117 reactor until the SOA growth ceased. For Exp. 1, 2, 6, and 7, 15 ppm NO at 5 L min^{-1} was injected for 5-
118 20 min several times until the SOA growth ceased. The NO concentration was usually on the order of tens
119 of ppb and always remained above a few ppb, making the bimolecular reaction with NO a favorable RO_2
120 reaction pathway. The experiment was initiated by turning on the irradiation of UV light approximately 20
121 min after the end of the last injection to ensure that particles and vapors were mixed well inside the reactor.

122 The procedure for “nighttime” experiments was the same until the end of the precursor VOC
123 injection. An oxidant precursor (i.e., N_2O_5) was pre-made in a flow tube by simultaneously injecting 500
124 ppm NO_2 (Matheson) at 0.4 L min^{-1} and $\sim 250 \text{ ppm O}_3$ (Jelight 610) at 0.5 L min^{-1} . A simple kinetic box
125 model was used to adjust the concentration of O_3 and flow rates of both NO_2 and O_3 to maximize the
126 production of N_2O_5 and minimize the concentration of O_3 , such that the VOC was dominantly oxidized by
127 nitrate radicals. Once N_2O_5 entered the reactor, it thermally decomposed to generate NO_2 and nitrate
128 radicals. VOC was usually depleted within the first 15 min of the experiment. For Exp. 8 and 14, the
129 injection order of precursor VOC and oxidant precursor was switched such that the injection of VOC
130 marked the beginning of the experiment. For Exp. 12 and 13, 25 ppm formaldehyde was added to the reactor
131 to enhance the branching ratio of $\text{RO}_2 + \text{HO}_2$ (Schwantes et al., 2015; Boyd et al., 2015) by injecting an
132 appropriate amount of formalin solution (37 % HCHO, Sigma-Aldrich) in the same manner as the injection
133 of H_2O_2 . We do not discuss the details of the effect of the injection order nor the effects of the RO_2 fate
134 here as they had negligible impact on the results concerning hydrolysis.

135

136 2.2. Instrumentation and data analysis

137 A High Resolution Time-of-Flight Aerosol Mass Spectrometer (HR-ToF-AMS; Aerodyne
138 Research Inc.) measured the concentrations of non-refractory organics (Org), sulfate (SO_4), nitrate (NO_3),

139 ammonium (NH_4), and chloride (Chl) (DeCarlo et al., 2006). The data were analyzed using PIKA v1.16I.
140 For the majority of nitrate-containing aerosol regardless of the class (i.e., inorganic or organic), the nitrate
141 moiety (i.e., $-\text{NO}_2$, $-\text{ONO}_2$, and $-\text{O}_2\text{NO}_2$) was known to be thermally fragmented into NO^+ and NO_2^+ and
142 was measured as NO_3 (Farmer et al., 2010). As many past studies have demonstrated the feasibility to
143 separate the contribution of inorganic ($\text{NO}_{3,\text{Inorg}}$) and organic nitrate ($\text{NO}_{3,\text{Org}}$) to the measured NO_3 based
144 on the ratio of NO^+ and NO_2^+ (Fry et al., 2009; Farmer et al., 2010; Xu et al., 2015b; Kiendler-Scharr et al.,
145 2016; Fry et al., 2018), we used Eq. (1) presented in Farmer et al (2010) to obtain $\text{NO}_{3,\text{Org}}$. R_{AN} (i.e.,
146 $\text{NO}^+/\text{NO}_2^+$ from ammonium nitrate) was obtained from the routine ionization efficiency calibration of HR-
147 ToF-AMS using 300 nm ammonium nitrate particles. The drawback of this method is that R_{ON} (i.e.,
148 $\text{NO}^+/\text{NO}_2^+$ from organic nitrate aerosol) could vary depending on the chemical composition (Xu et al.,
149 2015b). In addition, a non-negligible contribution of ammonium nitrate could be expected in experiments
150 with deliquesced seed aerosol owing to high solubility of HNO_3 . Thus, we obtained the R_{ON} measured in
151 low RH experiments for each system of VOC and oxidation condition. In order to account for changes in
152 R_{AN} over time, R_{ON} was scaled accordingly assuming that the ratio of R_{ON} to R_{AN} in the same system was
153 constant (Fry et al., 2013). R_{AN} , R_{ON} , and $R_{\text{ON}}/R_{\text{AN}}$ values obtained in this study were consistent with
154 previously reported values (Fry et al., 2009; Bruns et al., 2010; Boyd et al., 2015; Nah et al., 2016) and are
155 summarized in Table S1.

156 A Filter Inlet for Gases and AEROsols (FIGAERO) (Lopez-Hilfiker et al., 2014) coupled to a High
157 Resolution Time-of-Flight Iodide Chemical Ionization Mass Spectrometer (HR-ToF-I-CIMS; Aerodyne
158 Research Inc.) detected a suite of gaseous and particulate oxidized organic species as well as selected
159 inorganic species (Bertram et al., 2011; Lee et al., 2014). The operation of FIGAERO-HR-ToF-I-CIMS
160 was detailed in the previous studies (Nah et al., 2016; Sanchez et al., 2016). Reagent ions were generated
161 by flowing a mixture of CH_3I and dry ultra high purity (UHP) N_2 (Airgas) through a polonium-210 source
162 (NRD; Model P-2021). The instrument measured gaseous compounds by sampling air from the reactor at
163 $\sim 1.7 \text{ L min}^{-1}$ while collecting particles onto a Teflon filter. Upon completion of the collection period,
164 collected particles were desorbed by temperature-programmed dry UHP N_2 flow and subsequently analyzed

165 by HR-ToF-I-CIMS. Sensitivity could decrease if the amount of reagent ions were significantly depleted
166 and/or if the secondary chemistry in the ion-molecule reaction (IMR) chamber occurred at a significant
167 degree (Lee et al., 2014). To avoid changes in sensitivity among experiments, gas-phase sampling flow was
168 diluted with zero air immediately before the inlet such that the evaporation of aerosol was minimal. The
169 amount of aerosol collected on the filter was also adjusted by varying the sampling rate from 1 to 6 L min⁻¹
170 depending on the aerosol mass concentrations inside the reactor. Overall, the fraction of reagent ions to
171 the total ions was kept above 80 %. In addition, iodide ion chemistry has been known to be affected by the
172 water vapor pressure inside the IMR owing to the difference in thermodynamics between I⁻ and IH₂O⁻ to
173 analyte compounds (Lee et al., 2014). In order to minimize changes in the water vapor pressure inside the
174 IMR, a small continuous flow of humidified UHP N₂ (30-50 ccm) through a bubbler at a reduced pressure
175 was continuously added to the IMR directly. Therefore, while the instrument was not calibrated to report
176 the concentration of detected species, it was possible to quantitatively compare measured signal of each ion
177 among experiments because the instrument was operated under configurations that prevented undesired
178 changes in sensitivity. The data were analyzed using Tofware v2.5.11 and all the masses presented in this
179 study were I⁻ adducts.

180 A Scanning Mobility Particle Sizer (SMPS) that consisted of a Differential Mobility Analyzer (TSI
181 3040) and a Condensation Particle Counter (TSI 3775) was operated under the low flow mode with the
182 sheath flow of 2 L min⁻¹ to detect particles up to 1 μm in electrical mobility size. A Cavity Attenuated Phase
183 Shift spectroscopy (CAPS; Aerodyne Research Inc.) (Kebabian et al., 2005), an ultra-sensitivity NO_x
184 analyzer (Teledyne M200EU), and an UV absorption O₃ analyzer (Teledyne T400) measured NO₂, NO_x,
185 and O₃, respectively. In selected experiments, a Gas Chromatograph coupled to Flame Ionization Detector
186 (GC-FID; Agilent) was used to make sure that a desired amount of a precursor VOC was injected. Except
187 CAPS, NO_x analyzer, and O₃ analyzer, all instruments had their own dedicated sampling line.

188

189 3. Results and discussion

190 3.1. Chemical composition of secondary organic aerosol

191 Shown in Fig. 1 are the mass spectra of particle-phase species obtained from FIGAERO-HR-ToF-
192 I-CIMS at peak SOA growth. Many of the major species detected in this study are previously reported using
193 the same or different technique (Eddingsaas et al., 2012; Claflin and Ziemann, 2018; Boyd et al., 2015; Nah
194 et al., 2016; Lee et al., 2016; Romonosky et al., 2017). Concerning the chemical composition of SOA from
195 each system, a more distinct difference is observed between different oxidation conditions (i.e., hydroxyl
196 vs. nitrate radical oxidation) than between different precursor VOC (i.e., α -pinene vs. β -pinene). This is
197 expected as α -pinene and β -pinene have the same chemical formula and very similar structures while the
198 oxidation condition is distinctively different (Kroll and Seinfeld, 2008; Ziemann and Atkinson, 2012).

199 For “daytime” experiments where hydroxyl radicals are the dominant oxidants, the contribution of
200 ON (i.e., $C_xH_yN_{1,2}O_z$) and non-nitrated organics (i.e., $C_xH_yO_z$) are comparable and their contributions are
201 well spread out over a wide range of masses. A large contribution of $C_xH_yO_z$ is expected because the
202 formation of ON is a minor pathway in RO_2+NO (Perring et al., 2013). In Eddingsaas et al. (2012), the
203 major compounds reported in the α -pinene+OH system include $C_8H_{12}O_{4-6}$ and $C_{10}H_{16}O_{4,6}$, which are also
204 detected in our study. A suite of C_{10} ON from the chamber experiment of the α -pinene+OH system are
205 reported in Lee et al. (2016) with the chemical formula of $C_{10}H_{15,17,19}NO_{4-9}$. All of these masses are detected
206 in this study, though we observe a considerable contribution of $C_{<10}$ ON (i.e., $C_7H_{9,11}NO_6$ and
207 $C_9H_{13,15,17}NO_6$) as well as a small fraction of C_{10} dinitrate (i.e., $C_{10}H_{14,16}N_2O_{9,10}$) that has been rarely reported
208 (Fig. 1a). This significant contribution from species containing $C_{<10}$ indicates the large contribution of
209 fragmentation process that is a preferred pathway in high NO conditions (Kroll and Seinfeld, 2008;
210 Ziemann and Atkinson, 2012; Perring et al., 2013). It is possible that these species with $C_{<10}$ are thermally
211 decomposed products during the thermal desorption process (Stark et al., 2017). However, it is unlikely
212 that thermal decomposition plays a significant role for the SOA generated via hydroxyl radical oxidation
213 of monoterpenes because the desorption temperature for these compounds (i.e., peaking at ~ 50 - 70 °C) are
214 much lower than the temperature at which decarboxylation or dehydration reactions (>120 °C) are

215 expected to occur (Stark et al., 2017). SOA chemical composition of the β -pinene+OH system is similar to
216 that of the α -pinene+OH system but with a larger contribution of $C_xH_yO_z$.

217 Another interesting observation in the α - β -pinene+OH systems is that a selected class of
218 compounds (i.e., $C_{10}H_{13,15,17}NO_{5-8}$) with the same H/C exhibit the same the time evolutions regardless of
219 the number of oxygen (Fig. S1). This observation is consistent with the autoxidation mechanism, in which
220 highly oxidized molecules are formed in a short time scale (Ehn et al., 2014; Crouse et al., 2013; Jokinen
221 et al., 2015). The detection of compounds with $O_{>7}$ also supports the presence of autoxidation process;
222 otherwise it is extremely difficult to produce highly oxidized molecules in a timescale of a few hydroxyl
223 radical oxidation reactions. It is important to note that the concentration of NO in our experiments has been
224 mostly kept on the order of tens of ppb over the course of the experiments by a continuous injection of
225 dilute NO and, therefore, this result suggests that autoxidation is not a negligible pathway of RO_2 fate even
226 at a moderately high NO level in laboratory experiments and in polluted ambient environments. Indeed,
227 recent studies (Berndt et al., 2016; Xu et al., 2019; Pye et al., 2019) suggest that the autoxidation rate
228 constant for the α -pinene+OH system could be up to a few per second, which is comparable to the NO level
229 of ~ 10 ppb. The autoxidation rate constant as well as the role of NO in autoxidation based on this
230 observation will be discussed in details in a forthcoming publication.

231 In contrast, the signals of $C_xH_yN_{1-2}O_z$ are dominant in the nitrate radical oxidation condition,
232 indicating that the production of ON is greatly favored over non-nitrated organics. This observation is
233 consistent with a direct addition of a nitrate functional group to a double bond (Wayne et al., 1991; Ng et
234 al., 2017), whereas the formation of ON in the hydroxyl radical oxidation condition is a minor channel of
235 RO_2+NO reaction (Perring et al., 2013). Moreover, the contribution from species containing $C_{<10}$ is
236 minimal. This is because unlike hydroxyl radical oxidation, a hydrogen subtraction reaction by a nitrate
237 radical is less efficient and, thus, multi-generation oxidation is unlikely to occur within the timescale of
238 experiments (Wayne et al., 1991; Ng et al., 2017). This means that once the precursor VOC undergoes
239 functionalization upon the initial nitrate radical oxidation, it is not likely to experience fragmentation during

240 the experiment. Unlike “daytime” SOA, the distribution of masses is dominated by a few signature ions,
241 such as $C_{10}H_{15}NO_{5,6}$ and $C_{20}H_{32}N_2O_{8-10}$ (Fig. 1c and 1d). In Boyd et al. (2015), Nah et al. (2016), and Lee
242 et al. (2016), the major species reported in the α -/ β -pinene+ NO_3 systems are monomeric nitrate aerosol
243 (i.e., $C_{10}H_{13,15,17,19}NO_{4-10}$), while in this study a substantial contribution of dimeric species (i.e., $C_{20}H_{32}N_2O_{8-}$
244 $_{11}$) is observed. The abundant presence of dimeric compounds has been previously observed in some studies
245 on nitrate radical oxidation of α -/ β -pinene (Romonosky et al., 2017; Clafin and Ziemann, 2018) and
246 particle-phase reactions to produce such dimers have been proposed by Clafin and Ziemann (2018). Many
247 of the reported species in Clafin and Ziemann (2018) except the trimeric species (mass scan range not
248 extended to trimeric species in our study) are observed in our study. One major difference between Clafin
249 and Ziemann (2018) and this study is the substantial presence of monomeric nitrate aerosol (i.e., 30-60 %
250 by signal) in this study. This difference may be attributed to the difference in the amount of available
251 monomeric blocks to form dimer species. Assuming reversible dimerization process, the concentration of
252 dimer species shall be proportional to the square of monomer concentration, such that the monomer to
253 dimer ratio increases in a quadratic manner as the available monomer concentration decreases. Since the
254 amount of SOA formed in Clafin and Ziemann (2018) is approximately two orders of magnitude higher
255 than that in this study, the concentration of monomers in the particle-phase is higher, favoring a more
256 efficient formation of dimeric species. Together, these results suggest that the contribution of dimeric nitrate
257 aerosol could vary greatly depending on the concentrations of monomeric blocks at the specific time and
258 location.

259 Previous field studies have reported the mass spectra of ambient C_{10} pON obtained by FIGAERO-
260 HR-ToF-I-CIMS in rural Alabama site during the Southern Oxidant and Aerosol Study (SOAS) (Lee et al.,
261 2016) and in rural forest in Germany (Zhang et al., 2018). A comparison of the ambient mass spectra with
262 those obtained in this study reveals that average ambient pON resembles “daytime” pON more than
263 “nighttime” pON (Fig. S2). pON from “daytime” experiments has a distribution of masses centered around
264 $C_{10}H_{13,15,17}NO_7$, which is consistent with the ambient measurement data. On the other hand, nitrate radical

265 oxidation does not seem to oxidize organic species enough that the distribution of masses is skewed towards
266 a less-oxidized region (i.e., $C_{10}H_{13,15,17}NO_{5,6}$). However, it is difficult to draw a quantitative conclusion
267 simply based on this comparison because O_3 , another important oxidant at night, is not studied. Moreover,
268 an average lifetime of aerosol could extend up to a week and thus ambient aerosol is continuously exposed
269 to further oxidation while the experiments here are more applicable to freshly formed aerosol. In addition,
270 the use of $C_{10,p}ON$ alone may not be a good representative of monoterpene-derived pON as 42-74 % of pON
271 in this study contains fewer or more than 10 carbon (Table S2). Nonetheless, the chemical composition of
272 aerosol generated in this study is comparable to those in the atmosphere and, thus, the results shall be
273 directly applicable to relevant ambient conditions.

274

275 3.2. Hydrolysis of particulate organic nitrate

276 3.2.1. Proxy used to evaluate hydrolysis process

277 Various proxies using HR-ToF-AMS data have been used to infer ON hydrolysis in previous
278 studies. In Bean and Hildebrandt Ruiz (2016), NO_3 measured by an Aerosol Chemical Speciation Monitor
279 (ACSM, practically similar to how AMS operates and measures aerosol species) (Ng et al., 2011) is
280 normalized to SO_4 as a means to account for particle wall-loss and is fitted by an exponential function to
281 estimate the ON hydrolysis rate. On the other hand, Boyd et al. (2015) normalize NO_3 measured by HR-
282 ToF-AMS to Org and attribute the relative decay of NO_3/Org between humid (RH ~50 %) to dry (RH <5
283 %) conditions to hydrolysis. Other approaches include the SMPS-derived particle wall-loss correction of
284 NO_3 measured by HR-ToF-AMS followed by fitting its decay trend (Liu et al., 2012b) and the determination
285 of fraction of total (i.e., gas and particle) ON to the precursor VOC consumed as a function of RH using a
286 Fourier-Transform InfraRed spectroscopy (FTIR). Below, we systematically examine the use of different
287 proxies using HR-ToF-AMS data to infer hydrolysis and discuss how the corresponding results are
288 interpreted.

289 Figure 2 shows the time series of Org, NO_3 , SO_4 , and NH_4 measured by HR-TOF-AMS for α -
290 pinene+ NO_3 system. There is a substantial difference in NO_3 for the same VOC system but under different

291 reactor RH and phase state of seed particles (Exp. 10 and 11), while Org and SO₄ concentrations are similar.
292 The spike in NO₃ in high RH wet seed experiment (Fig. 2b) is attributed to the uptake of N₂O₅ and/or
293 dissolution of HNO₃ into aqueous aerosol followed by neutralization with ammonia to produce ammonium
294 nitrate. This is consistent with the sharp increase in molar ratio of NH₄/SO₄ to higher than 2, which is the
295 theoretical value for AS particles. It is also possible that inorganic nitrate is generated via hydrolysis of
296 gaseous ON that is too volatile to condense but is soluble enough to dissolve in aqueous aerosol and, thus,
297 only appears in high RH experiments. Since we do not have a way to quantitatively differentiate the
298 contribution of the aforementioned sources, the focus of this study is on hydrolysis of pON that is condensed
299 driven by volatility. However, further study is required to investigate the hydrolysis of volatile yet soluble
300 gaseous ON, and the approach must be different from the comparison between low and high RH
301 experiments to obtain meaningful results.

302 To evaluate the extent of pON hydrolysis, the contributions of inorganic nitrate (NO_{3,Inorg}) and
303 organic nitrate (NO_{3,Org}) to the measured NO₃ need to be calculated. Firstly, NO_{3,Org} is estimated by
304 subtracting NO₃ associated with excess NH₄. Secondly, NO_{3,Org} is derived from NO⁺/NO₂⁺ approach (Sect.
305 2.2.). Figure S3 shows the comparison of NO_{3,Org} estimated by these two independent methods for the α-
306 pinene+NO₃ system. It is clear that NO_{3,Org} from both methods are consistent and that there is a considerable
307 contribution of NO_{3,Inorg} to NO₃ in the experiment. We note the contribution of NO_{3,Inorg} to NO₃ can vary
308 depending on experimental conditions with a range from to 28 to 90 % for all experiments in this study.
309 Nevertheless, these results demonstrate that for laboratory experiments with high RH and wet seeds, when
310 using HR-ToF-AMS data to infer hydrolysis, it is important to separate the measured NO₃ into NO_{3,Inorg} and
311 NO_{3,Org}.

312 Once NO₃ is separated into NO_{3,Inorg} and NO_{3,Org}, we evaluate whether the normalization of NO_{3,Org}
313 to SO₄ and Org provides a consistent decay trend. Photooxidation of α-pinene (Exp. 3-5) is used as a case
314 system. As hydrolysis is a reaction where liquid water is directly involved in, it is expected that the rate of
315 hydrolysis will change proportionally as a function of aerosol water content. Based on the hygroscopicity

316 parameter for AS ($\kappa = 0.53$) (Petters and Kreidenweis, 2007) and for ambient LO-OOA ($\kappa = 0.08$) (Cerully
317 et al., 2015) that has a substantial contribution from p ON (Xu et al., 2015a), estimated aerosol water contents
318 at peak SOA growth in Exp. 3-5 are approximately 0, 1, and 26 $\mu\text{g m}^{-3}$, respectively. Figure S4 illustrates
319 that AS seed particles are indeed effloresced in Exp. 4 (high RH, dry AS) but not in Exp. 5 (high RH, wet
320 AS). These mass concentrations of aerosol water translate to 0, 6, and 36 mol L^{-1} , respectively, under the
321 assumption that SOA is miscible with liquid water. It is speculated that SOA formed in Exp. 3-5 are miscible
322 with water because (1) the measured O/C ratio in HR-ToF-AMS (Canagaratna et al., 2015) is close to 0.7,
323 which is near the lower end but above the liquid-liquid phase separation condition (Song et al., 2012) and
324 (2) there is evidence of aqueous-phase reactions which highly depend on the availability of aerosol water,
325 as discussed in Sect. 3.3. Thus, the decay rate of $\text{NO}_{3,\text{Org}}$ normalized to SO_4 and/or Org between Exp. 4 and
326 Exp. 5 shall differ by a factor of 6 based on the molar concentrations of aerosol water.

327 Figure 3a shows the mass ratio of $\text{NO}_{3,\text{Org}}/\text{SO}_4$ and the decay rate as a characteristic time in Exp. 3-
328 5. The characteristic times of Exp. 4 and 5 (4.4 vs. 4.0 h) do not differ regardless of the molar concentrations
329 of aerosol water, suggesting that the decreasing trend in $\text{NO}_{3,\text{Org}}/\text{SO}_4$ may not be due to changes in aerosol
330 water content and p ON hydrolysis, but arise from the difference in the reactor humidity alone. A comparison
331 of $\text{NO}_{3,\text{Org}}/\text{SO}_4$ and $\text{NO}_{3,\text{Org}}/\text{Org}$ also reveals that these two proxies capture a different range of decay
332 mechanisms. Figure 3b shows the relative decay trend of $\text{NO}_{3,\text{Org}}/\text{SO}_4$ and $\text{NO}_{3,\text{Org}}/\text{Org}$ between Exp. 4 (high
333 RH) and Exp. 3 (low RH). If hydrolysis is a dominant decay mechanism of p ON, the trend of $\text{NO}_{3,\text{Org}}/\text{Org}$
334 would be identical to that of $\text{NO}_{3,\text{Org}}/\text{SO}_4$. This is because the organic moiety of hydrolysis product is
335 generally considered to have a substituted alcohol group (Boschan et al., 1955) and to have a relatively
336 similar vapor pressure and shall remain in the particle phase (Pankow and Asher, 2008). However, the
337 measured decay trend of the two proxies is greatly different. It is possible that some organic moiety of
338 hydrolysis product could be significantly more volatile and repartition back to the gas phase (Rindelaub et
339 al., 2016; Bean and Hildebrandt Ruiz, 2016) and, thus, both organics and HNO_3 formed from hydrolysis
340 evaporate. In this case, not only $\text{NO}_{3,\text{Org}}$ but also some fraction of Org would decrease because Org measured
341 by HR-ToF-AMS includes the contribution from the organic part of p ON. This will lead to the relatively

342 smaller decrease in $\text{NO}_{3,\text{Org}}/\text{Org}$ compared to $\text{NO}_{3,\text{Org}}/\text{SO}_4$. We can reconstruct the decay rate of $\text{NO}_{3,\text{Org}}/\text{Org}$
343 assuming 1) the decay rate of $\text{NO}_{3,\text{Org}}/\text{SO}_4$ is solely due to hydrolysis of pON and 2) the maximum
344 contribution of pON to OA is 35 % (see Fig. 4 and discussions below). The reconstructed decay rate of
345 $\text{NO}_{3,\text{Org}}/\text{Org}$ is shown in Fig. 3b. As observed in the figure, the decay rate of the reconstructed $\text{NO}_{3,\text{Org}}/\text{Org}$
346 is much larger than the measured $\text{NO}_{3,\text{Org}}/\text{Org}$. This suggests that hydrolysis is not the only loss process
347 reflected in the decreasing trend of $\text{NO}_{3,\text{Org}}/\text{SO}_4$, while $\text{NO}_{3,\text{Org}}/\text{Org}$ is likely a better proxy that isolates
348 hydrolysis from other loss processes. The likely important loss process manifested in $\text{NO}_{3,\text{Org}}/\text{SO}_4$ is the
349 loss of organic vapors to the walls of the reactor (Matsunaga and Ziemann, 2010; Krechmer et al., 2016;
350 Huang et al., 2018; Loza et al., 2010; Mevay et al., 2014; Zhang et al., 2015; Zhang et al., 2014; La et al.,
351 2016). For example, Huang et al. (2018) observe that the decay of isoprene hydroxyl nitrate depends on the
352 reactor humidity. Therefore, $\text{NO}_{3,\text{Org}}/\text{Org}$ is a better proxy to infer hydrolysis of pON than others.

353

354 3.2.2. Hydrolysis lifetime of particulate organic nitrate

355 In order for the data to be easily comparable with those reported in models or using other technique,
356 the use of general terms instead of the AMS specific terms (i.e., $\text{NO}_{3,\text{Org}}$ and Org) can be convenient. We
357 define pON as the total mass concentration of particulate organic nitrate (includes organics part and nitrate
358 part of the ON compounds) and OA as the total mass concentration of organic aerosol (includes nitrate and
359 non-nitrated organics). The inclusion of nitrate mass in OA is important as the contribution of nitrate
360 functional groups to the total organic aerosol concentration is large. The conversion method from
361 $\text{NO}_{3,\text{Org}}/\text{Org}$ into pON/OA is illustrated in Eq. (1).

$$\frac{\text{pON}}{\text{OA}} = \left(\frac{\frac{\text{NO}_{3,\text{Org}}}{\text{Org}}}{1 + \frac{\text{NO}_{3,\text{Org}}}{\text{Org}}} \right) * \left(\frac{\text{MW}_{\text{pON}}}{\text{MW}_{\text{NO}_3}} \right) \quad (1)$$

362 MW_{pON} represents the average molecular weight of pON per nitrate functional group estimated from
363 FIGAERO-HR-ToF-I-CIMS data, and MW_{NO_3} indicates the molecular weight of nitrate (i.e., 62 g mol^{-1}).
364 Since MW_{pON} does not significantly vary during the course of experiments (i.e., relative standard deviation

365 of <1.2 %), the average value is applied to each experiment. The variability of MW_{pON} among different
366 systems is also found to be small, ranging from 229 to 238 $g\ mol^{-1}$ and, thus, an average MW_{pON} is used for
367 experiments where FIGAERO-HR-ToF-I-CIMS data are not available. Figure 4 shows the time-series data
368 of pON/OA for all the systems investigated in this study.

369 For “nighttime” experiments, the relative ratio of $C_xH_yN_{1-2}O_z$ and $C_xH_yO_z$ obtained from
370 FIGAERO-HR-ToF-I-CIMS data in Fig. 1 does not appear to match well with pON/OA from HR-ToF-
371 AMS data. For example, the signals are dominated by $C_xH_yN_{1-2}O_z$ in the β -pinene+ NO_3 system, as shown
372 in Fig. 1d, while pON/OA is at most 0.5, as shown in Fig. 4d. The discrepancy would be attributed to the
373 overestimation of Org (in particular, C_xH_y family) in HR-ToF-AMS and/or underestimation of $C_xH_yO_z$ in
374 FIGAERO-HR-ToF-I-CIMS. Relative ionization efficiency (RIE) of less-oxidized organic species in HR-
375 ToF-AMS is experimentally measured to be higher at least by a factor of 2 (Xu et al., 2018b). As previously
376 reported (Boyd et al., 2015), the HR-ToF-AMS mass spectrum of SOA formed from β -pinene+ NO_3
377 contains significant amounts of C_xH_y fragments, indicating the less-oxidized nature of SOA from β -
378 pinene+ NO_3 . For example, if the true RIE of Org by β -pinene+ NO_3 SOA were to be a factor of 2 higher
379 than the default RIE of Org (i.e., 1.4), the reported concentration of Org would have been overestimated by
380 a factor of 2, such that actual pON/OA would have been higher than reported in Fig. 4d. On the other hand,
381 an iodide reagent ion is not quite selective to detect less oxidized species, which could overestimate the
382 contribution of pON to OA (Aljawhary et al., 2013). Nonetheless, this discrepancy between HR-ToF-AMS
383 and FIGAERO-HR-ToF-I-CIMS data, however, should not affect the results regarding the hydrolysis
384 lifetime and hydrolyzable fraction of pON presented later.

385 As illustrated in Fig. 4, the time series of pON/OA stabilizes fairly quickly in most of the
386 experiments, regardless of RH and/or the phase state of seed aerosol. This suggests that the timescale of
387 pON hydrolysis in the systems studied is significantly shorter or longer than the timescale of our
388 experiments. It is also evident from Fig. 4 that pON/OA in high RH experiments are always lower than that
389 in low RH experiments. These two observations imply that the rate of pON hydrolysis may be fast enough
390 that the decay trend of pON compared to OA is not visibly manifested, though a clear difference of pON/OA

391 between low and high RH experiments is exhibited as a result of fast hydrolysis. Since no sudden, drastic
392 change in $p\text{ON/OA}$ is observed except for a few initial data points, we conclude that the hydrolysis lifetime
393 of hydrolyzable $p\text{ON}$ for α -/ β -pinene derived ON shall be no more than 30 min (i.e., 3 data points in Fig.
394 4). Particle acidity is found to enhance the rate of hydrolysis in prior study (Rindelaub et al., 2016), though
395 no clear difference is observed between experiments with AS and SA+MS seed particles (i.e., Exp. 5 and
396 2). $p\text{ON}$ formed from hydroxyl and nitrate radical oxidation of α -pinene and β -pinene may not require a low
397 pH to undergo hydrolysis at a rate comparable to the timescale of chamber experiments.

398 Comparing with the results from past chamber studies reporting a $p\text{ON}$ hydrolysis lifetime of 3 to
399 6 h (Liu et al., 2012b; Bean and Hildebrandt Ruiz, 2016; Boyd et al., 2015), our estimated hydrolysis
400 lifetime is substantially shorter, but is consistent with the range (i.e., 1 min to 8.8 h) reported in studies
401 using the bulk solution (Darer et al., 2011; Hu et al., 2011; Jacobs et al., 2014; Rindelaub et al., 2016) (Fig.
402 5). In Liu et al. (2012) and Bean and Hildebrandt Ruiz (2016), the hydrolysis lifetime is derived from the
403 decay rate of NO_3 corrected for the particle wall loss or normalized to SO_4 . As demonstrated in Sect. 3.2.1.,
404 this NO_3/SO_4 decay rate is likely affected by other loss processes, such as vapor wall loss, and, thus, is not
405 a good proxy to estimate the hydrolysis lifetime. The apparent discrepancy does not stem from the
406 contradiction in the obtained data itself but rather in the data interpretation. Indeed, the lifetime estimated
407 based on the decay of $\text{NO}_{3,\text{Org}}/\text{SO}_4$ in our study is 4 h (Fig. 3a) that is consistent with 6 and 3 h reported in
408 Liu et al. (2012) and Bean and Hildebrandt Ruiz (2016). On the other hand, in Boyd et al. (2015) the
409 hydrolysis lifetime is estimated based on the decay rate of NO_3/Org . The discrepancy in the reported
410 hydrolysis lifetime here could be attributed to the fact that NO_3 is not separated into $\text{NO}_{3,\text{Org}}$ and $\text{NO}_{3,\text{Inorg}}$.
411 Figure S5 shows our data analyzed in the same manner as Boyd et al. (2015). The lifetime calculated based
412 on the decay is 2.2 h, which is close to the reported 3 h (Boyd et al., 2015). The reduction of NO_3/Org in
413 Fig. S5 (~30 %) is greater than in Boyd et al. (2015) (10 %), which could be because (1) the amount of
414 N_2O_5 , a source of inorganic nitrate, used in our study is slightly larger and (2) RH in our study is higher by
415 10-20 %, which may have allowed greater uptake of N_2O_5 to produce inorganic nitrate.

416 In previous bulk solution studies where the concentration of interested organic nitrate (in particular
417 hydroxyl nitrate) in aqueous solution rather than in aerosol water is monitored over time, it is unlikely that
418 the data interpretation is affected by other loss processes present in chamber experiments, such as vapor
419 wall-loss. It is also common to monitor the organic moiety of hydrolysis product (Darer et al., 2011), while
420 it is extremely difficult in chamber experiments where hundreds of organic species are present at the same
421 time, leading to the difficulty in accurately measuring the hydrolysis lifetime in chamber experiments.
422 Based on the comprehensive analysis we demonstrate above on evaluating p ON hydrolysis in chamber
423 experiments, we recommend the use of the hydrolysis lifetime reported in this study, which is no more than
424 30 min, for p ON formed from α -pinene and β -pinene.

425

426 3.2.3. Hydrolyzable fraction of particulate organic nitrate

427 The fraction of hydrolyzable p ON (F_H) can be directly estimated from the difference in p ON/OA
428 between low and high RH experiments shown in Fig. 4. Although we show that hydrolysis is substantially
429 faster than the timescale of chamber experiments in our study, there still appears a clear difference in
430 p ON/OA between high RH experiments but with a different phase state of seed aerosol (i.e., Exp. 4 and 5).
431 The difference mass spectra among Exp. 3-5 obtained from FIGAERO-HR-ToF-I-CIMS reveal that the
432 difference in p ON/OA between Exp. 4 and 5 does not arise from the reduction in p ON but from the increase
433 in non-nitrated organics (Fig. 6). The reason for this OA increase with the abundant presence of aerosol
434 water is speculated to be uptake and other aqueous-phase reactions than hydrolysis and is briefly discussed
435 in Sect. 3.3. Thus, the absolute difference in p ON/OA between low RH, dry seed and high RH, dry seed
436 experiments best indicates F_H . Depending on the fate of the organic moiety of the hydrolysis product (i.e.,
437 stay in the particle phase or repartition back to the gas phase), F_H varies. Since we are unable to determine
438 the fate of hydrolysis product, an upper and lower limit of F_H are reported as a range of F_H . For the α -
439 pinene+OH system, 23-32 % of p ON formed undergoes hydrolysis within the timescale of the experiments.
440 For the other systems with no experiment under high RH with dry seed aerosol, the same level of additional

441 contribution from non-nitrated organics encountered in α -pinene+OH system is assumed and F_H is scaled
442 accordingly. For the β -pinene+OH, α -pinene+NO₃, and β -pinene+NO₃ systems, 27-34, 9-17, and 9-15 %
443 of pON are found hydrolyzable within the timescale of the experiments. Table 2 summarizes the hydrolysis
444 lifetime and F_H in the systems explored in this study.

445 F_H has been only reported in several studies (Liu et al., 2012b; Boyd et al., 2015; Zare et al., 2018).
446 The determination of F_H is essential because the assumption that all pON hydrolyzes biases the relative
447 importance of hydrolysis among the loss mechanisms of pON and NO_x. Boyd et al. (2015) report that F_H of
448 pON formed via β -pinene+NO₃ is ~10 %, which is in a good agreement with our range of 9-15 %. From a
449 perspective of predicted molecular structures of pON, <5 % of pON from β -pinene+NO₃ are tertiary (Clafin
450 and Ziemann, 2018) that is expected to undergo hydrolysis in minutes (Darer et al., 2011; Hu et al., 2011).
451 In our study, a considerable contribution of monomeric (C₁₀) pON is observed (Fig. 1d), while dimeric (C₂₀)
452 pON is dominant in Clafin and Ziemann (2018). This may indicate that monomeric pON is more susceptible
453 to hydrolysis such that F_H in this study is slightly higher than expected based on the proposed molecular
454 structures of pON in Clafin and Ziemann (2018).

455 F_H for α -/ β -pinene+OH systems are higher than those from α -/ β -pinene+NO₃ systems. This trend
456 is consistent with the understanding that pON via hydroxyl radical oxidation have a larger fraction of tertiary
457 nitrate groups, which are significantly more susceptible to hydrolysis (Darer et al., 2011; Hu et al., 2011)
458 than those formed via nitrate radical oxidation (Ng et al., 2017). Although the relative trend of F_H between
459 α -/ β -pinene+OH and α -/ β -pinene+NO₃ systems is consistent, the magnitude of F_H in the α -/ β -pinene+OH
460 system appears to be smaller than expected based on the tertiary nitrate fraction estimated via the explicit
461 gas-phase chemical mechanism (Browne et al., 2013; Zare et al., 2018). In previous studies, F_H are
462 estimated to be 62 and 92 % for α -/ β -pinene+OH systems, respectively. However, our results indicate F_H is
463 23-32 and 27-34 % for the same systems (Fig. 5). The chemical mechanism used in Browne et al. (2013)
464 and Zare et al. (2018) are based on the Master Chemical Mechanism (MCM) that is well known in the
465 degradation chemistry of VOC in the gas phase (Jenkin et al., 1997; Saunders et al., 2003). However, the

466 same mechanism performs poorly in regards to the chemical composition of SOA (Faxon et al., 2018) as
467 well as the prediction of SOA formation (Ruggeri et al., 2016; Boyd et al., 2017) when equipped with gas-
468 particle partitioning modules based on the absorptive gas-particle partitioning theory (Pankow, 1994). It is,
469 therefore, reasonable to argue that the chemical composition of p ON could greatly differ from that of total
470 ON predicted by the MCM. Thus, F_H reported in this study provides the fundamental experimental
471 constraints on p ON hydrolysis, that can be used in regional and global models for elucidating potential
472 impacts of ON on nitrogen budget and formation of ozone and aerosol.

473

474 3.3 Signature of other aqueous-phase reactions than hydrolysis

475 As briefly discussed in the above section, the presence of elevated level of aerosol water seems to
476 have enhanced the contribution of small (i.e., $C_{<9}$) but more-oxidized organic species to SOA. As shown in
477 Fig. 5c, the enhancement is observed for a variety of non-nitrated organic aerosol including $C_4H_{6,8}O_3$,
478 $C_4H_4O_4$, $C_5H_6O_5$, $C_7H_{8,10}O_4$, and $C_8H_{8,10}O_{4,5}$, while p ON overall neither increase nor decrease. $C_5H_6O_5$ has
479 been reported as a product of the aqueous-phase reaction of α -pinene derived compounds (Aljawhary et al.,
480 2016). Other compounds, such as $C_4H_4O_4$, $C_7H_{8,10}O_4$, and $C_8H_{10}O_5$, also appear to result from the aqueous
481 processing because compounds with similar chemical formulae but with slightly higher degrees of oxidation
482 (i.e., $C_4H_4O_5$, $C_7H_{10}O_5$, and $C_8H_{12}O_6$) are reported in Aljawhary et al. (2016). The reason for this less
483 oxidized nature of SOA in this study may be attributed to our experiments being performed in moderately
484 high NO conditions that promotes a higher contribution of a carbonyl group than a hydroperoxyl group,
485 which is preferred in low NO conditions. In Aljawhary et al. (2016), the starting compound is a product in
486 low NO conditions (pinonic acid, $C_{10}H_{16}O_3$). Thus, it is reasonable that products of the aqueous processing
487 in this study are slightly less oxidized than observed in Aljawhary et al. (2016).

488 The enhancement of non-nitrated organic aerosol in FIGAERO-HR-ToF-I-CIMS may be due to
489 aqueous processing of species in the particles in the presence of aerosol water. This can come from further
490 reactions of semi/low-volatile species in the particle phase, or reactive uptake of volatile (but highly water-
491 soluble) species into the aerosol followed by subsequent aqueous-phase reactions to form low-volatility

492 products (Ervens et al., 2011). A comparison of the average thermogram at peak SOA growth among Exp.
493 3-5 indicates a higher contribution of low-volatility compounds in Exp. 5 than in Exp. 3 and 4, as illustrated
494 by the bimodal peaks (Fig. S6). Given the same degree of gas-phase oxidation expected among Exp. 3-5,
495 these results show that that aqueous chemistry in wet aerosol contributes to the further formation of low-
496 volatility compounds. Overall, the highest average degree of oxidation ($O/C = 0.77$) is observed in high RH
497 wet aerosol experiment (Expt. 5). The effect of particle water on monoterpene SOA formation warrants
498 further studies.

499

500 3.4 Atmospheric implications

501 There is emerging evidence that monoterpene SOA greatly contribute to atmospheric aerosol in the
502 Southeastern U.S. (Zhang et al., 2018; Xu et al., 2018a). ON is no exception; a substantial fraction of p ON
503 is considered to be from monoterpenes (Lee et al., 2016; Huang et al., 2019; Xu et al., 2015a). While C_{10}
504 p ON measured in FIGAERO-HR-ToF-I-CIMS is a good tracer of monoterpene derived p ON, we show that
505 a fair amount of α -/ β -pinene p ON is found as $C_{<10}$ or C_{20} depending on the oxidation condition. This implies
506 that the contribution of monoterpene derived p ON could be substantially underestimated when only
507 considering C_{10} p ON. Fraction of p ON with different number of carbon reported in this study (Table S2) is
508 a useful parameter to quantitatively determine the contribution of monoterpenes derived p ON to total p ON.

509 Many previous modeling studies using ambient measurement data as constraints report that the
510 lifetime of p ON is likely several hours (Pye et al., 2015; Fisher et al., 2016; Lee et al., 2016; Zare et al.,
511 2018). Hydrolysis of p ON is used as a dominant loss process with the lifetime of several hours to improve
512 the concentration of modeled OA (Pye et al., 2015) and to improve the concentrations of gaseous and
513 particulate ON (Fisher et al., 2016). If the ambient p ON concentration is indeed governed by a loss process
514 with a few hours of lifetime, our results imply that the particle-phase hydrolysis may not be the only
515 dominant loss process because the hydrolysis lifetime reported in this study is significantly shorter. Other
516 potential but less-studied loss mechanisms of ON and p ON include deposition (Nguyen et al., 2015),
517 photolysis (Muller et al., 2014), and aqueous photooxidation (Romonosky et al., 2017; Nah et al., 2016).

518 For instance, enhanced photolysis rate is observed for carbonyl nitrate derived from isoprene (Muller et al.,
519 2014), while no similar study is available for monoterpene derived ON in literature. Also, it has been
520 demonstrated that different monoterpene pON can have drastically different photochemical fates (Nah et
521 al., 2016). Taken together, results from this study highlight the importance to investigate other potential
522 loss processes of monoterpene derived pON.

523 Aside from the hydrolysis lifetime, many modeling studies assume F_H as unity (Pye et al., 2015;
524 Fisher et al., 2016; Lee et al., 2016). Even when F_H is considered, the value of F_H used in other studies is
525 still substantially higher than estimated in this study (Browne et al., 2013; Zare et al., 2018). The use of
526 higher F_H would result in overestimating the contribution of hydrolysis as a loss process of pON and NO_x .
527 While hydrolysis is considered as a permanent sink of NO_x , many other loss processes, such as further
528 hydroxyl radical oxidation and photolysis, are considered as a temporary reservoir of NO_x . If the relative
529 importance of pON fates in models was not accurate, the role of ON in NO_x cycling and the formation
530 potential of ozone could have been inaccurately interpreted. Therefore, results from this study regarding
531 the hydrolysis lifetime and F_H serve as experimentally constrained parameters for chemical transport
532 models to accurately evaluate the role of ON in regards to nitrogen budget and the formation of ozone and
533 fine aerosol.

534

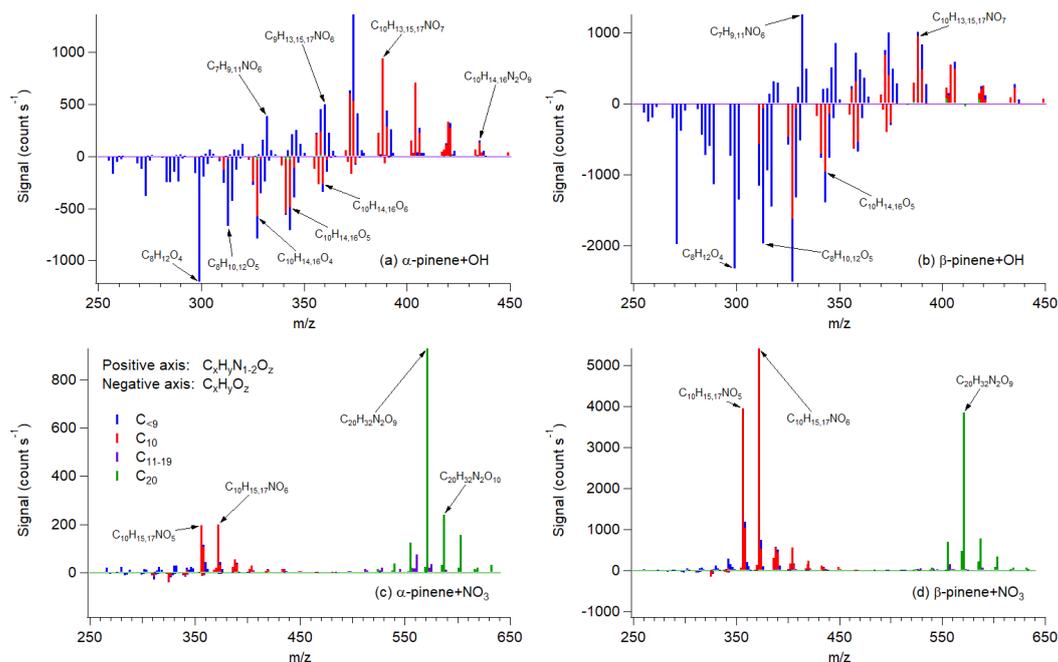

535 **Author contribution**

536 M.T. designed and performed the research and analyzed the data with substantial inputs from N.L.N. M.T.
537 and N.L.N. wrote the manuscript.

541 AGS-1555034 and by National Oceanic and Atmospheric Administration (NOAA) NA18OAR4310112.
542 The FIGAERO-HR-ToF-CIMS has been purchased through NSF Major Research Instrumentation (MRI)
543 Grant 1428738.

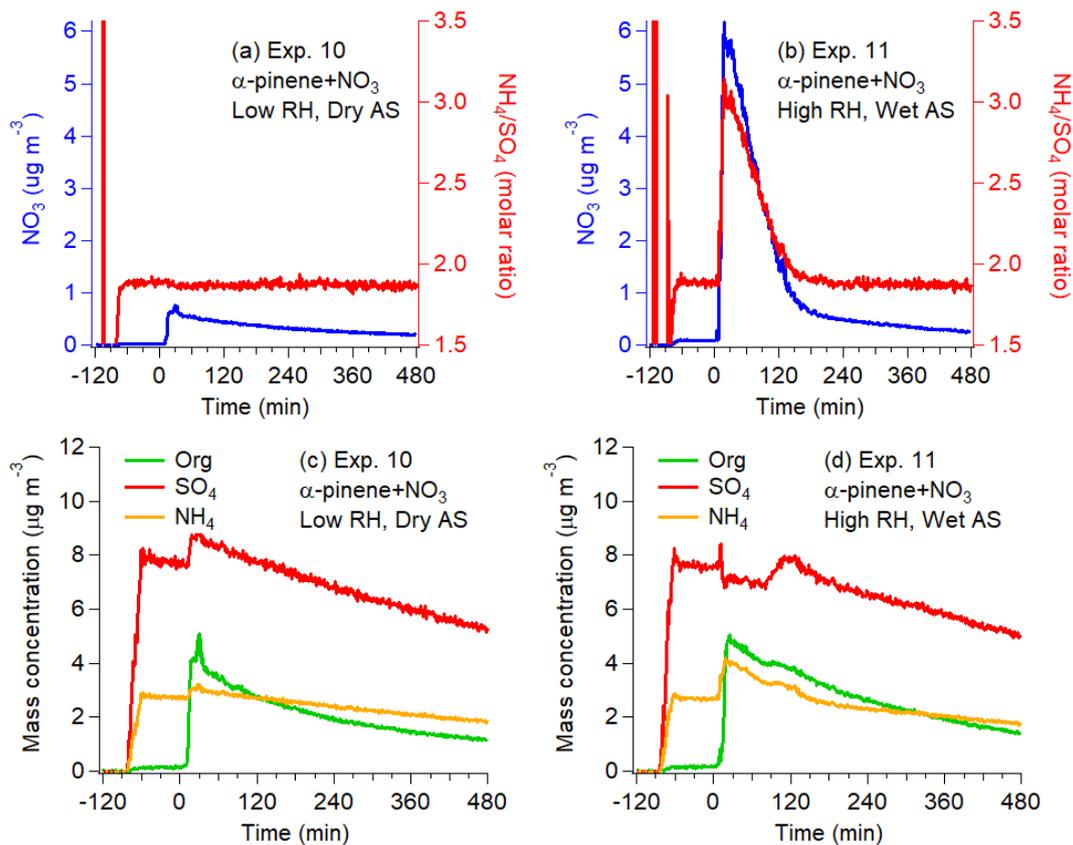

545

546 Figure 1. FIGAERO-HR-ToF-I-CIMS mass spectra of SOA in (a) α -pinene+OH from Exp. 3, (b) β -547 pinene+OH from Exp. 6, (c) α -pinene+NO₃ from Exp. 10, and (d) β -pinene+NO₃ from Exp. 14. Top portion548 of each panel represents C_xH_yN₁₋₂O_z, whereas bottom represents C_xH_yO_z. Bars are colored by the number

549 of carbon as noted in the legend. Prominent masses are labeled with the corresponding chemical formulae

550 without an iodide ion.

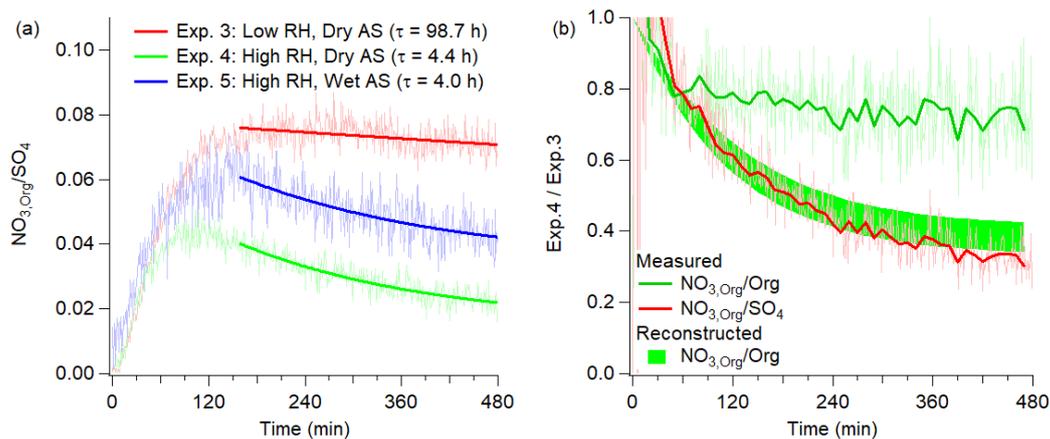

551

552

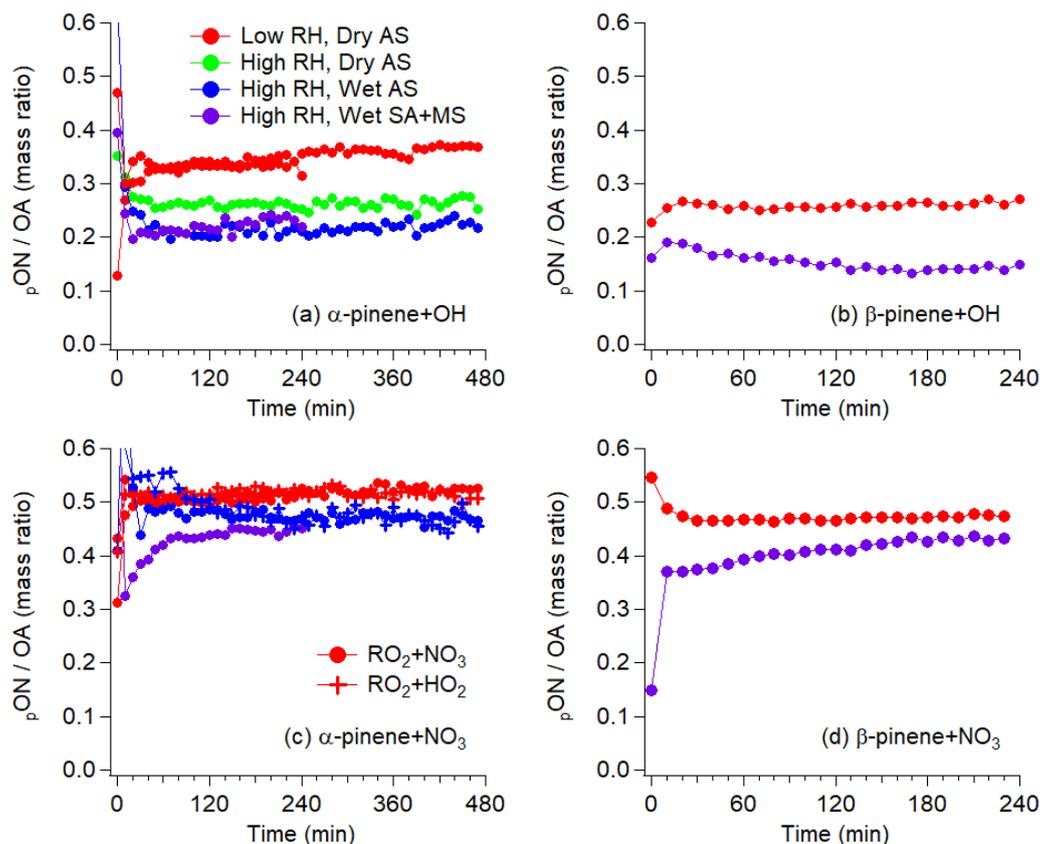

553 Figure 2. (a, b) NO_3 concentration and the molar ratio of NH_4 to SO_4 and (c, d) concentrations of Org, SO_4 ,
554 and NH_4 measured by HR-ToF-AMS. Data presented in Panels (a) and (c) are from Exp. 10 (low RH, dry
555 AS), while those in Panels (b) and (d) are from Exp. 11 (high RH, wet AS). These two experiments are
556 essentially the same except for RH and phase state of seed aerosol.

557

558

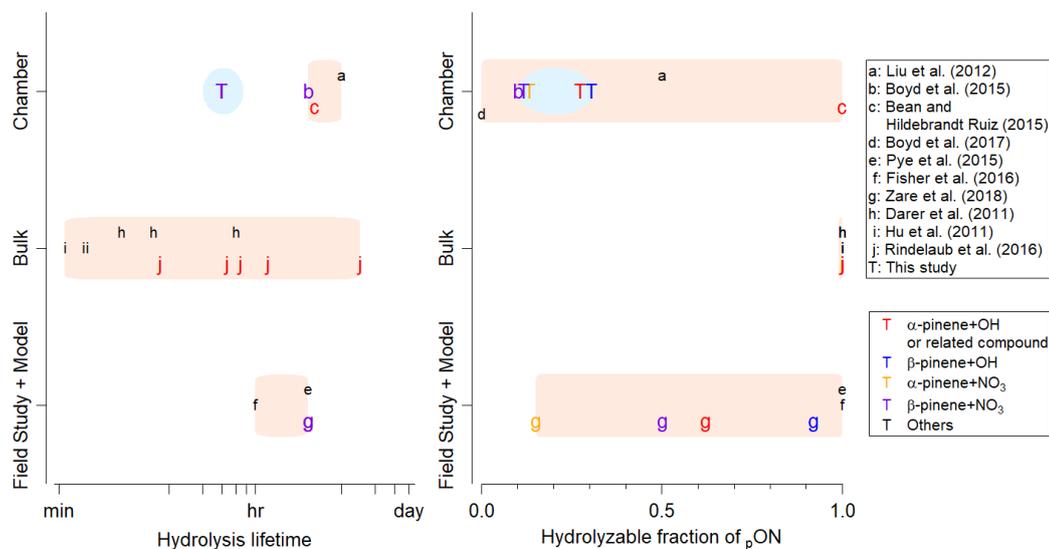

559 Figure 3. (a) Time-series data of $\text{NO}_{3,\text{Org}}/\text{SO}_4$ from Exp. 3-5 (α -pinene+OH) and the exponential fits with560 corresponding characteristic times. (b) $\text{NO}_{3,\text{Org}}/\text{Org}$, $\text{NO}_{3,\text{Org}}/\text{SO}_4$, reconstructed $\text{NO}_{3,\text{Org}}/\text{Org}$ based on the561 decay rate of $\text{NO}_{3,\text{Org}}/\text{SO}_4$.

562

563 Figure 4. Time-series data of p_{ON}/OA in (a) α -pinene+OH from Exp. 1-5, (b) β -pinene+OH from Exp. 6-
564 7, (c) α -pinene+NO₃ from Exp. 8-13, and (d) β -pinene+NO₃ from Exp. 14-15. Data points are colored by
565 conditions concerning reactor RH and phase state of seed aerosol. For α -pinene+NO₃, data points are also
566 shaped differently depending on the expected dominant RO₂ fate.

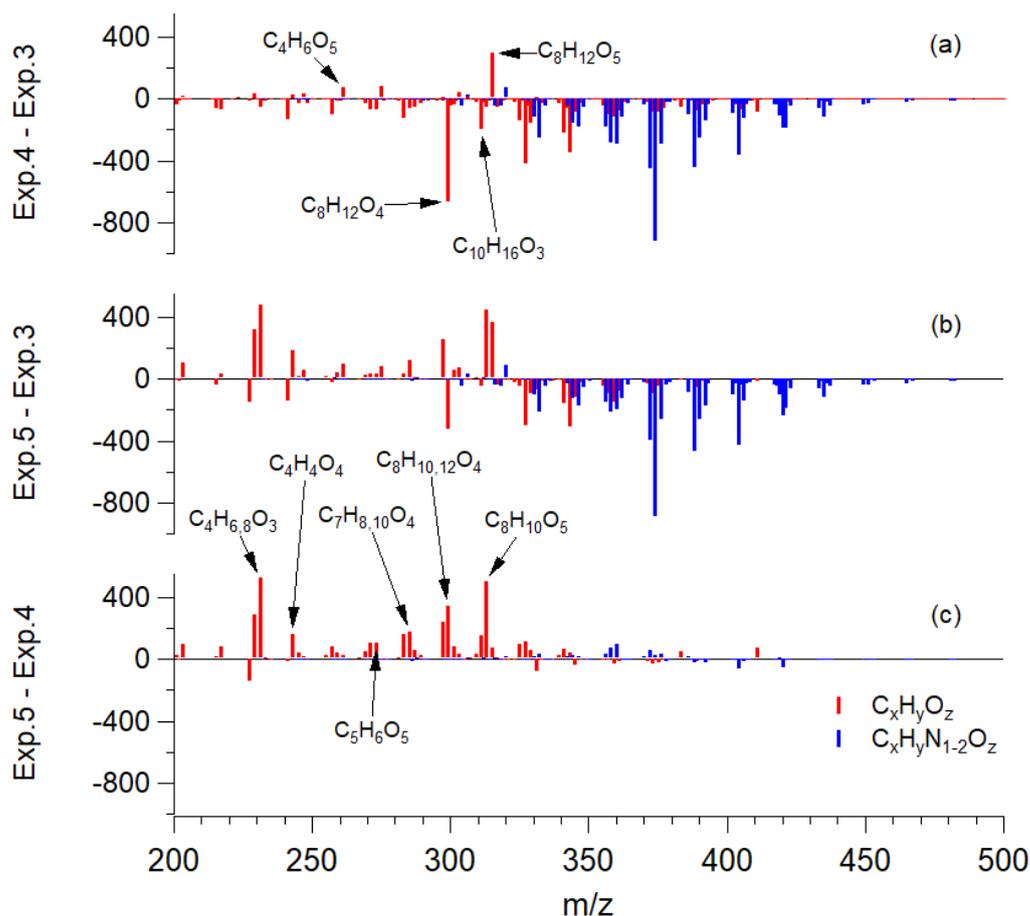

567

568

569 Figure 5. Comparison of hydrolysis lifetime of organic nitrate and hydrolyzable fraction of pON in
 570 literature. “Chamber” refers to laboratory studies of organic nitrate aerosol via chamber experiments,
 571 “Bulk” refers to laboratory studies of organic nitrate compounds using bulk solution measurements, and
 572 “Model” refers to modeling studies using ambient measurement data as constraints. Data points are colored
 573 by the system of VOC and oxidant condition explored in this study and are alphabetized based on the
 574 reference. Pink shaded regions are ranges reported in literature, while blue shaded regions are ranges
 575 reported in this study.

576

577

578 Figure 6. FIGAERO-HR-ToF-I-CIMS difference mass spectra of SOA in α -pinene+OH. (a) Exp. 4 (high
579 RH, dry AS) minus Exp. 3 (low RH, dry AS). (b) Exp. 5 (high RH, wet AS) minus Exp. 3 (low RH, dry
580 AS). (c) Exp. 5 (high RH, wet AS) minus Exp. 4 (high RH, dry AS). Bars are colored by the difference in
581 chemical composition (i.e., red for $C_xH_yO_z$ and blue for $C_xH_yN_{1-2}O_z$). Prominent masses are labeled with
582 the corresponding chemical formulae without an iodide ion.

583

584 Table 1. Summary of experimental conditions considered in this study.

Exp.	Precursor VOC	Oxidant precursor	Reactor RH	Seed
1	α -pinene (25 ppb)	H ₂ O ₂ (2 ppm), NO (6 ppb min ⁻¹)	~5 %	Effloresced AS ^b
2	α -pinene (25 ppb)	H ₂ O ₂ (2 ppm), NO (6 ppb min ⁻¹)	~50-70 % ^a	Deliquesced SA+MS ^c
3	α -pinene (25 ppb)	H ₂ O ₂ (2 ppm), NO (2 ppb min ⁻¹)	~5 %	Effloresced AS
4	α -pinene (25 ppb)	H ₂ O ₂ (2 ppm), NO (2 ppb min ⁻¹)	~50-70 %	Effloresced AS
5	α -pinene (25 ppb)	H ₂ O ₂ (2 ppm), NO (2 ppb min ⁻¹)	~50-70 %	Deliquesced AS
6	β -pinene (25 ppb)	H ₂ O ₂ (2 ppm), NO (6 ppb min ⁻¹)	~5 %	Effloresced AS
7	β -pinene (25 ppb)	H ₂ O ₂ (2 ppm), NO (6 ppb min ⁻¹)	~50-70 %	Deliquesced SA+MS
8	α -pinene (12 ppb)	N ₂ O ₅ (80 ppb)	~5 %	Effloresced AS
9	α -pinene (12 ppb)	N ₂ O ₅ (80 ppb)	~60-70 %	Deliquesced SA+MS
10	α -pinene (12 ppb)	N ₂ O ₅ (80 ppb)	~5 %	Effloresced AS
11	α -pinene (12 ppb)	N ₂ O ₅ (80 ppb)	~60-70 %	Deliquesced AS
12	α -pinene (12 ppb)	N ₂ O ₅ (80 ppb), HCHO (25 ppm)	~5 %	Effloresced AS
13	α -pinene (12 ppb)	N ₂ O ₅ (80 ppb), HCHO (25 ppm)	~60-70 %	Deliquesced AS
14	β -pinene (12 ppb)	N ₂ O ₅ (80 ppb)	~5 %	Effloresced AS
15	β -pinene (12 ppb)	N ₂ O ₅ (80 ppb)	~60-70 %	Deliquesced SA+MS

585 ^aThe target for the initial reactor RH is ~70 %. However, the irradiation of UV light increases the reactor
 586 temperature by several degree Celsius and hence decreases RH.

587 ^bAmmonium sulfate

588 ^cSulfuric acid and magnesium sulfate

589

590 Table 2. Hydrolysis lifetime and corresponding fraction of hydrolyzable p ON.

System	Hydrolysis lifetime	Hydrolyzable fraction (F_H) ^a
α -pinene+OH	<30 min	23–32 %
β -pinene+OH	<30 min	27–34 %
α -pinene+NO ₃	<30 min	9–17 %
β -pinene+NO ₃	<30 min	9–15 %

591 ^aLower or higher limit of hydrolyzable p ON fraction is based on the assumptions that organic moiety of

592 hydrolysis products remains in aerosol or partitions back to the gas phase.
