

1 **Figure S1: Maps of the average dust mass density (kg m^{-2}) based on reanalysis data of MERRA-2. The**
 2 **analysis was focused in up to three days from the sampling period around the area of the sampling site (the**
 3 **blue marker). Darker shades represent higher amount of suspended dust. The maps, combined with the air**
 4 **mass backtrajectory analysis, used to trace the potential source of the dust storm, marked by the green**
 5 **arrows (see also green symbols in Figure 1 in the main text). The data was derived from the Giovanni**
 6 **website (<http://giovanni.sci.gsfc.nasa.gov/giovanni>).**

99 **Figure S4: Representative SEM micrographs of a filter that was collected in SDS1 event. The different**
100 **color shading represents the different chemical elements that were indicated by EDX analysis. The filter**
101 **was covered by particles with a common occurrence of Si and Al, suggesting that mineral dust was**
102 **dominated. Some mineral dust particles were also rich in Ca and Mg, while S, Fe and K were mostly**
103 **concentrated in specific particles. Occurrence of NaCl particles was also observed based on the coexistence**
104 **of Na and Cl in the same particles.**

134 **Table S1: The expected percentage range of the chosen minerals in airborne particles. The values are based**
135 **on values from Atkinson et al. (2013) and Boose et al. (2016) of transported mineral dust.**
136

Mineral	Atkinson et al. (2013)	Boose et al. (2016)	Used in this study
K-feldspar	1 – 25 %	2.4 - 5.7 %	1 - 25%
Na/Ca-feldspar	0.8 – 13.8 %	3.1 – 7.6 %	0.8 – 13.8%
Quartz	7 – 67 %	13.6 – 24.1	7 – 67%
