Replies to Reviewer 1:

We would like to thank the reviewer for the constructive comments and suggestions. Below we reply to every comment made by the reviewer. The original comments are numbered and repeated, followed by our answers.

Specific comments:

Comment 1: Introduction: The authors could consider to also reference the study by Liu et al. (J.Clim 2018, <https://doi.org/10.1175/JCLI-D-17-0439.1>) which looked at patterns of climate response to a regional Asian aerosol perturbation in multiple models, including by performing a breakdown of the response into different energy budget terms

C1

(though far less comprehensively than in this study) – predominantly with regard to understanding the precipitation change although the temperature responses are also discussed.

Reply 1: We have added the reference to Liu et al. (2018) and discuss the relevant findings in that paper in the Introduction and in Results sections. Specifically, we added: L65 in revised MS: “Liu et al. (2018) showed that the temperature effects of idealized Asian aerosol perturbations spread across the Northern hemisphere in a multi-model PDRMIP study, and that increases in Asian sulfate aerosols strongly suppressed Asian monsoon precipitation by enhancing horizontal atmospheric heat transport to the region and raising surface pressure.” L270 in revised MS: “A similar global climate sensitivity of $0.58 \pm 0.23 \text{ K/(Wm}^{-2}\text{)}$ for a 10-fold increase in Asian anthropogenic sulfate aerosols was found in models that participated to the multi-model intercomparison project PDRMIP (Liu et al., 2018).”

Comment 2: L91: By “background aerosol” I assume this refers to natural aerosol sources (e.g. dust, sea salt)? It might be useful just to explicitly say this here (e.g. “The background *natural* aerosols...” or something similar), so it’s clear that only natural aerosols are represented differently between the two models.

Reply 2: We discuss the background aerosols now in more detail: L101 in revised MS: “The background pre-industrial aerosols (mainly consisting of natural organics and sulfate, sea salt and dust) for ECHAM6.1 are prescribed using the climatology of Kinne et al. (2013), while for NorESM1, they are simulated by the model’s bottom-up aerosol microphysics scheme (Kirkevåg et al. 2013) (see also Fig. 2 and Appendix A in Fiedler et al. (2019) describing the pre-industrial aerosols for both of the applied models, and the related discussion).”

Comment 3: L133-134: consider mentioning that that SH and LH are the *net downwards* sensible and latent heat fluxes (at least this is what they seem to be, from the sign of the terms in the equation), since this is opposite to the conventional sign of

C2

these terms which are more commonly defined as net upwards.

Reply 3: We thank the reviewer for pointing out the need for this clarification. Indeed, the net sensible and latent heat fluxes were taken as “net downwards” fluxes. We have now replaced “SH” and “LH” by “-SH’(arrow up)” and “-LH’(arrow up)” to follow the conventional sign convention.

Comment 4: L167-168: “We mark … collectively as CONV” – consider adding something like “as together they represent the convergence of energy” or something similar, so that it is clear where the abbreviation CONV comes from.

Reply 4: Added.

Comment 5: L390-391: “changes in the clear-sky longwave responses spread the surface temperature warming over both hemispheres” - maybe I haven’t understood the plots properly, but based on Fig 2 this statement doesn’t seem right. Looking at Fig 2G, it appears to me that the LW_clr term is highly restricted to the northern hemisphere, and is mostly zero or slightly negative in the southern hemisphere. In fact it appears to be one of the few terms which *doesn’t* contribute much to the southern hemisphere response. But maybe I’ve misunderstood the figure here, so please correct me if so! On a related note, if LW_clr is indeed the main term responsible for spreading the response to both hemispheres, there would seem to be a chicken-and-egg question of causality: Earlier in the manuscript I think the authors attribute the LW_clr response to water vapour and lapse-rate feedbacks, but presumably this requires there to first be some initial warming due to another process. I realise these are equilibrium responses so it is hard to diagnose, but again it seems counter-intuitive that LW_clr could be the main redistributor into the southern hemisphere unless it’s the feedback to another term which is already moving heat into the southern hemisphere. Do the authors have any hypothesis what that initial process might be? (Again I understand this might be hard to determine from these simulations, mainly I’m curious just to satisfy myself that there’s a plausible hypothesis).

C3

Reply 5: It is indeed true that LW_clr is mainly restricted to Northern hemisphere, and this result also applies to both applied models separately. Hence, the original claim that “clear-sky longwave responses spread the surface temperature warming over both hemispheres” was inaccurately formulated. On the related note, we see the changes in heat transport as the primary driver of the remote feedbacks, while the full disentangling of feedbacks from responses is difficult. But we could envision that large scale circulation changes (such as a shift in ITCZ) might also lead to changes in LW_clr. We changed the sentence to: L409 in revised MS: “The driver of the wide geographical spreading of the temperature response appears to be the strong tendency of atmospheric heat transport to regulate surface warming over the region of diminished aerosol forcing while simultaneously enhancing the warming in remote locations. Also, changes in the clear-sky longwave responses associated at least in part with increased water vapor further amplify the surface temperature warming over the Northern hemisphere.”

Comment 6: L400: From Fig 4, it looks to me like the LW_clr term actually contributes more than the albedo term to both the seasonality and the total Arctic amplification (which incidentally is the same as Pithan and Mauritsen find). However the current wording makes it sound like the LW_clr term is secondary to the ice-albedo feedback. Maybe say something like “However, the longwave clear-sky response contributes *even more* to the seasonality and the overall Arctic warming” or something similar? Again, unless I have misinterpreted Fig 4 in which case please correct me!

Reply 6: Again we agree, and now we emphasize the role of LW_clr as the main contributor of the Arctic temperature response. We modified the sentence to: L422 in revised MS: “However, it is the longwave clear-sky response that contributes most to the seasonality and the overall Arctic warming, supporting the strong role of temperature feedbacks in the Arctic warming (Pithan and Mauritsen, 2014) also in case of South and East Asian anthropogenic aerosol removal.”

Other technical corrections:

C4

C7: L38 and L54: Reference misspelt, should be 'Westervelt'.

R7: Corrected.

C8: L43: Reference should be Lamarque et al., not just Lamarque.

R8: Corrected.

C9: L98: There appears to be a missing word - I assume it should say "aerosol radiative forcings" or "aerosol radiative effects" or something similar.

R9: Corrected to "aerosol radiative forcings".

C10: L102: Typo - "NoreSM1" should say "NorESM1"

R10: Corrected.

C11: L334: KK -> K

R11: Corrected.

C12: L597 & L643: Kelvins -> kelvin or kelvins (lower case k, pluralisation optional).

R12: Corrected to kelvins.
