17 Abstract

18 Size and effective density (ρ_e) are important properties of aerosol particles and are
19 related to their influences on human health and the global climate. The volume
20 equivalent diameter (D_{ve}) is an intrinsic property that is used to evaluate particle size.
21 ρ_e , defined as the ratio of particle density to a dynamic shape factor (χ), is used to
22 characterize the physical property of a particle as an alternative to particle density.
23 However, it is still challenging to simultaneously characterize the D_{ve} and ρ_e of particles.
24 Here, we present a novel system that classifying particles with their aerodynamic
25 diameter (D_a) by aerodynamic aerosol classifiers (AAC) and determining their vacuum
26 aerodynamic diameter (D_{va}) by single particle aerosol mass spectrometry (SPAMS) to
27 achieve a measurement of D_{ve} and ρ_e . The reliability of the AAC-SPAMS system for
28 accurately obtaining D_{ve} and ρ_e is verified based on the results that the deviation between
29 the measured values and the theoretical values is less than 4% for the size-resolved
30 spherical polystyrene latex (PSL). The AAC-SPAMS system is applied to characterize
31 the D_{ve} and ρ_e of $(\text{NH}_4)_2\text{SO}_4$ and NaNO_3 particles, suggesting that these particles are
32 aspherical and their ρ_e are independent of particle size. Finally, the AAC-SPAMS
33 system is deployed in a field measurement, showing that it is a powerful technique to
34 characterize the chemically-resolved D_{ve} and ρ_e of particles in real time.

35 1. Introduction

36 Size and particle density (ρ_p) are critical parameters of aerosol particles in
37 quantifying the impact of aerosols on air quality, human health and global climate
38 change (Buseck and Posfai, 1999; Poschl, 2005; Pitz et al., 2003). Effective density (ρ_e)
39 has been adopted to characterize the physical property of a particle as an alternative to
40 ρ_p , since ρ_p for aspherical aerosol particles is hardly measured (Sumlin et al., 2018;
41 Katrib et al., 2005). Size and ρ_e govern the transport properties of a particle both in the
42 atmosphere and in the human respiratory system (Seinfeld and Pandis, 1998; Liu and
43 Daum, 2008) and directly/indirectly influence the potential of the particle to absorb or
44 reflect solar radiation (Tang, 1997; Zhao et al., 2019; Liu and Daum, 2008). ρ_e can also
45 provide information concerning particle morphology (Yon et al., 2015) and serve as a
46 tracer for atmospheric processing (Guo et al., 2014; Yin et al., 2015; Liu et al., 2015).
47 However, the quantitative relationship between aerosol properties, namely, size and ρ_e ,
48 and their effects on air quality, human health and global climate change is not yet well
49 understood, which is partly because important aerosol properties cannot be measured
50 by current techniques.

51 **Size.** Size is a fundamental property of particles, which can be parameterized by the
52 physical quantity of volume equivalent diameter (D_{ve}). Defined as the diameter of a
53 spherical particle with the same volume as the particle (DeCarlo et al., 2004), D_{ve} is an
54 intrinsic physical quantity that can be used to evaluate the actual size of the particle.
55 However, to date, atmospheric science usually describes particle size by other diameter
56 definitions, such as the electric mobility diameter (D_m), aerodynamic equivalent

57 diameter (D_a) and vacuum aerodynamic equivalent diameter (D_{va}), whose relationships
58 with D_{ve} are shown in Eqs. (1)-(3), respectively:

59
$$\frac{D_m}{C_c(D_m)} = \frac{D_{ve}}{C_c(D_{ve})} \chi_t, \quad (1)$$

60
$$D_a = D_{ve} \sqrt{\frac{\rho_p C_c(D_{ve})}{\chi_t \rho_0 C_c(D_a)}}, \quad (2)$$

61
$$D_{va} = \frac{\rho_p D_{ve}}{\rho_0 \chi_v}, \quad (3)$$

62 where $C_c(D)$ is the Cunningham slip correction factor, χ_t and χ_v represent the aerosol
63 dynamic shape factor (χ) in the transition regime and in the free-molecule regime,
64 respectively, and ρ_0 represents the unit density of 1.0 g/cm³. From the definitions, it can
65 be seen that D_m , D_a , and D_{va} are originally derived from D_{ve} , but in actuality, they do
66 not reflect the actual size of the particle. Meanwhile, D_{ve} cannot be easily obtained,
67 which limits its application in the scientific community.

68 **Effective density.** At present, three definitions of ρ_e are introduced in atmospheric
69 science (DeCarlo et al., 2004): the first definition (ρ_e^I) is the ratio of the measured
70 particle mass (m_p) to the particle volume (V) calculated assuming a spherical particle
71 with a diameter equal to the measured D_m ; the second definition (ρ_e^{II}) is the ratio of D_m
72 and D_{va} ; and the third definition (ρ_e^{III}) is the ratio of ρ to χ , all of which are expressed
73 in Eqs. (4)-(6), respectively.

74
$$\rho_e^I = \frac{6m_p}{\pi D_m^3} \quad (4)$$

75
$$\rho_e^{II} = \frac{D_{va}}{D_m} \rho_0 \quad (5)$$

76
$$\rho_e^{III} = \frac{\rho_p}{\chi} \quad (6)$$

77 When the above equations are combined with Eqs. (1) and (3), the final forms of
78 ρ_e^I and ρ_e^{II} can be expressed as Eqs. (7) and (8), respectively:

79
$$\rho_e^I = \frac{\rho}{\chi^3} \cdot \left(\frac{C_c(D_{ve})}{C_c(D_m)} \right)^3 \quad (7)$$

80
$$\rho_e^{II} = \frac{\rho}{\rho_0} \cdot \frac{C_c(D_{ve})}{\chi^2 \cdot C_c(D_m)} \quad (8)$$

81 The detailed derivation will be presented in a separate paper, in which we demonstrate
82 that ρ_e^I and ρ_e^{II} have the inherent characteristics of decreasing with increasing particle
83 size. Therefore, it will introduce systemic error when assessing the particle impacts on
84 visibility, human health and climate from the physical quantities in ρ_e^I and ρ_e^{II} . In
85 contrast, ρ_e^{III} is independent of particle size. Previously, ρ_e^{III} for the spherical particles
86 was derived from Mie modelling of the scattering signals collected by single particle
87 mass spectrometry (Moffet and Prather, 2005). However, there is no effective
88 technique to achieve the measurement of ρ_e^{III} for aspherical particles. Thus, for
89 reference, the symbol ρ_e in the following text refers to the definition of ρ_e^{III} .

90 The aim of the present work is to develop a method to obtain D_{ve} and ρ_e . The
91 established system of an aerodynamic aerosol classifier (AAC)-single particle aerosol
92 mass spectrometry (SPAMS) is capable of characterizing the D_a and D_{va} of particles,
93 which can be applied to theoretically derive D_{ve} and ρ_e . To verify the reliability of the
94 AAC-SPAMS system, we apply it to measure the D_{ve} and ρ_e of the spherical particles
95 of polystyrene latex (PSL). The results are in good agreement with the theoretical values.
96 Finally, the AAC-SPAMS system is applied to measure the D_{ve} and ρ_e for $(\text{NH}_4)_2\text{SO}_4$
97 and NaNO_3 particles and for the chemically-resolved atmospheric particles.

98

99 2. Experimental section

100 2.1 Measurement system

101 Figure 1 shows a schematic diagram of the AAC-SPAMS system. The particles are
102 first dried by a diffusion drying tube (TSI 9302, USA), classified by AAC (Cambustion
103 Ltd., UK) based on the aerodynamic diameters D_a , and then transported into SPAMS in
104 which the D_{va} and the mass spectra of individual particles are obtained. The working
105 principle of the AAC is described in detail elsewhere (Tavakoli and Olfert, 2013). AAC
106 consists of two coaxial cylinders that rotate at the same rotational speed. Polydisperse
107 particles enter into the space between the cylinders (i.e., classification column) and
108 experience a centrifugal force that causes them to move toward the outer cylinder. The
109 particles to be classified can leave the classification column with the particle-free sheath
110 flow and finally exit the AAC with the sample flow. Thus, the D_a values of classified
111 particles can be derived from their relationship with their relaxation time (τ), as shown
112 in Eq. (9):

$$113 \quad \tau = \frac{c_c(D_a) \cdot \rho_0 \cdot D_a^2}{18\mu} \quad (9)$$

114 where μ is the gas dynamic viscosity. Particles with large relaxation times impact and
115 adhere to the outer cylinder, while particles with small relaxation times exit the
116 classifier with the exhaust flow.

117 Detailed information about the operation of SPAMS (Hexin Analytical Instrument
118 Co., Ltd., China) is described elsewhere (Li et al., 2011). Briefly, the particles are
119 introduced into the vacuum system through a 0.1 mm critical orifice and are gradually
120 collimated into a beam in the aerodynamic lens. Two continuous diode Nd:YAG laser
121 beams (532 nm) are used to aerodynamically size the particles, which are subsequently
122 desorbed/ionized by a pulsed laser (266 nm) that is triggered based on the velocity of a

123 specific particle. The generated positive and negative ions are recorded with the
124 corresponding particle size. The D_{va} of the particle is related to the transit time between
125 the two laser beams (532 nm) in SPAMS, which can be obtained by using a calibration
126 curve generated from the measured transit times of a PSL series with predefined sizes
127 (nominal diameters).

128

129 2.2 Experiments and sampling schedule

130 Dried spherical PSL (Nanosphere Size Standards, Duke Scientific Corp., Palo Alto)
131 ($\rho_p = 1.055 \text{ g/cm}^3$ and $\chi = 1.0$) with D_{ve} values of 203.0 nm, 310.0 nm, 510.0 nm, and
132 740.0 nm were used in the AAC-SPAMS system. The PSL particles were first classified
133 by AAC, and then their D_{va} values were obtained by SPAMS. ACC-SPAMS was also
134 applied to the particles of $(\text{NH}_4)_2\text{SO}_4$ ($\rho_p = 1.77 \text{ g/cm}^3$) and NaNO_3 ($\rho_p = 2.26 \text{ g/cm}^3$)
135 with D_a values of 250.0 nm, 350.0 nm, 450.0 nm and 550.0 nm.

136 For field observations, the AAC-SPAMS system was placed in an urban area building
137 to characterize the D_{ve}, ρ_e and chemical compositions of aerosol particles. The sampling
138 inlet was hung 2.5 meters from the third floor (~12 m above ground level). Ambient
139 aerosol particles were introduced into the AAC through a 5 m long conductive silicone
140 tube with an inner diameter of 6 mm and a $\text{PM}_{2.5}$ cyclone inlet. The overall sampling
141 flow was 3 L/min, and the residence time was approximately 5 seconds. Sampled
142 particles were classified by the AAC as one of four D_a : 250.0 nm, 350.0 nm, 450.0 nm
143 and 550.0 nm. The sampling time for the particles of each D_a was approximately 10
144 minutes. From July 6th to 8th, 2019, approximately 100,000 ionized particles were

145 obtained. The sampling details are shown in Table S1.

146

147 **2.3 Theoretical derivation of D_{ve} and ρ_e from D_a and D_{va}**

148 D_{ve} is the accurate physical quantity of the size of a particle. ρ_e is an alternative
149 property for ρ_p , which is consistent with the property of ρ_p in terms of being independent
150 of particle size. These two properties cannot yet be measured for unknown particles by
151 current techniques. In this study, the calculations of D_{ve} and ρ_e for unknown particles
152 are theoretically derived from D_a and D_{va} . Combining Eqs. (2) and (3), we obtain the
153 following Eq. (10):

$$154 \quad C_{(D_a)} \frac{D_a^2}{D_{va}} = D_{ve} C_{(D_{ve})} \frac{\chi_v}{\chi_t} \quad (10)$$

155 Based on the approximation between χ_v and χ_t ($\chi_v \approx \chi_t = \chi_a$) (DeCarlo et al., 2004), Eq.
156 (10) becomes Eq. (11):

$$157 \quad C_{(D_a)} \frac{D_a^2}{D_{va}} = D_{ve} C_{(D_{ve})} \quad (11)$$

158 If the D_a and D_{va} of an unknown particle can be measured, its D_{ve} will be calculated
159 according to Eq. (11). Finally, the ρ_e value of the particles is calculated by the D_{va} and
160 D_{ve} values according to Eq. (12):

$$161 \quad \rho_e = \frac{\rho_p}{\chi_a} = \frac{D_{va}}{\rho_0 \cdot D_{ve}} \quad (12)$$

162 Thus, we can obtain both the D_{ve} and ρ_e values of unknown particles based on the D_a
163 and D_{va} values. Because the AAC and SPAMS instruments have the ability to determine
164 D_a and D_{va} , the AAC-SPAMS system, which is developed in this study, can be used to
165 obtain the D_{ve} and ρ_e values for unknown particles.

166

167 **3. Results and discussion**

168 **3.1 Verification of the AAC-SPAMS system to obtain D_{ve} and ρ_e**

169 The D_{va} distribution of PSL particles with predefined D_{ve} values after screening by
170 the AAC is shown in Figure S1. We used Gaussian fitting to obtain the peak D_{va} for
171 each size PSL with an R-squared fitting coefficient (R^2) over 0.98. Each fitting has a
172 full width at half maximum (FWHM) of 6.6%, 4.4%, 2.3% and 2.2%, and the
173 corresponding peaks are 215.8 nm, 319.0 nm, 532.1 nm and 803.5 nm, respectively.
174 Substituting the D_a and D_{va} values of PSL into Eq. (11), the measured D_{ve} ($D_{ve,me}$) of
175 PSL from AAC-SPAMS system is 203.6 nm, 309.7 nm, 511.6 nm and 737.2 nm,
176 respectively (Figure 2a). Thus, the deviations between the theoretical D_{ve} ($D_{ve,th}$) and
177 $D_{ve,me}$ values are 0.3%, -0.1%, 0.3% and -0.4%, respectively. On the other hand, the
178 measured ρ_e ($\rho_{e,me}$) values of the particles are calculated from the D_{va} and $D_{ve,me}$ values
179 with Eq. (12), and the $\rho_{e,me}$ values are 1.06 g/cm³, 1.03 g/cm³, 1.04 g/cm³, and 1.09
180 g/cm³ (Figure 2b). Furthermore, based on a ρ_p of 1.055 g/cm³ and a χ of 1.0 for PSL
181 particles, the deviations of $\rho_{e,me}$ are 0.5%, -2.4%, -1.4%, and 3.3%, respectively. That
182 is, the deviations of $D_{ve,me}$ and $\rho_{e,me}$ characterized by the AAC-SPAMS system are within
183 1% and 4%, respectively. We therefore conclude that the AAC-SPAMS system is highly
184 accurate for obtaining aerosol D_{ve} and ρ_e .

185

186 **3.2 Application of the AAC-SPAMS system for obtaining D_{ve} and ρ_e of $(\text{NH}_4)_2\text{SO}_4$**
187 **and NaNO_3**

188 Figure S2 shows the D_{va} distributions of $(\text{NH}_4)_2\text{SO}_4$ and NaNO_3 particles, which have

189 D_a values of 250.0, 350.0, 450.0, and 550.0 nm, as screened by the AAC. The D_{va} peaks
190 are obtained by Gaussian fitting, with R^2 values over 0.93 and FWHM values ranging
191 from 7.6% to 10.6%. The $(\text{NH}_4)_2\text{SO}_4$ particles have D_{va} values of 300.0, 418.0, 551.1,
192 and 695.1 nm (Figure S2), which correspond to particles possessing $D_{ve,me}$ values of
193 177.3, 254.4, 331.8, and 409.3 nm, respectively, according to Eq. (11). Substituting the
194 values of D_{va} and $D_{ve,me}$ into Eq. (12), the $\rho_{e,me}$ values are 1.74, 1.60, 1.65, and 1.74
195 g/cm^3 (Figure 3a), respectively. Similarly, the selected NaNO_3 particles are determined
196 to have D_{va} values of 321.0, 454.9, 599.8, and 755.3 nm (Figure S2), corresponding to
197 $D_{ve,me}$ values of 150.1, 218.2, 287.0, and 355.9 nm, respectively. The $\rho_{e,me}$ values of the
198 NaNO_3 particles are 2.21, 2.03, 2.05, and 2.14 g/cm^3 for the four particle sizes (Figure
199 3b), respectively. Figure 3 also shows that the $\rho_{e,me}$ values of the NaNO_3 and $(\text{NH}_4)_2\text{SO}_4$
200 particles at four size slightly deviate from their average values, which are identical with
201 the deviation phenomenon for the $\rho_{e,me}$ of PSL particles. These deviations are derived
202 from the measurement of the particle D_{va} in the SPAMS which size calibration curve
203 possesses the systematic error.

204 Taking the systematic error into account, the slight difference of the $\rho_{e,me}$ values for
205 the four sizes suggests that the ρ_e of $(\text{NH}_4)_2\text{SO}_4$ and NaNO_3 particles is independent of
206 particle size from 250 nm to 550 nm. This pattern is divergent with the previous studies,
207 which showed that effective density decreased as the size increasing (Zelenyuk et al.,
208 2006; Zhang et al., 2016a). It is caused by the difference of the definitions of the
209 effective density. The definitions of effective density used in previous studies possessed
210 the inherent characteristics of decreasing with the increasing particle size, which will

211 be discussed in a separate paper. The definition of effective density used in this study
212 will keep constant as long as the χ_a of the particles does not change with particle size.
213 The average $\rho_{e,me}$ values of $(\text{NH}_4)_2\text{SO}_4$ and NaNO_3 particles are calculated to be $1.68 \pm$
214 0.07 and $2.11 \pm 0.08 \text{ g/cm}^3$, respectively. The average $\rho_{e,me}$ values are lower than that
215 the ρ_p of $(\text{NH}_4)_2\text{SO}_4$ (1.77 g/cm^3) and NaNO_3 (2.27 g/cm^3), which is caused that the
216 $\rho_{e,me}$ is determined by both of ρ_p and χ_a . According to Eq. (12), the χ_a of $(\text{NH}_4)_2\text{SO}_4$ and
217 NaNO_3 particles with different D_a are calculated to be 1.02, 1.10, 1.07, and 1.02 and to
218 be 1.03, 1.12, 1.11, and 1.06, respectively. Thus, the average χ_a values of the $(\text{NH}_4)_2\text{SO}_4$
219 and NaNO_3 particles are determined to be 1.05 ± 0.04 and 1.08 ± 0.04 , respectively,
220 which can be used to parameterize their morphology.

221 The average χ_a values of the $(\text{NH}_4)_2\text{SO}_4$ and NaNO_3 particles indicate that these
222 particles are aspherical. The asphericity of $(\text{NH}_4)_2\text{SO}_4$ determined by AAC-SPAMS
223 system is consistent with the previous studies reporting that the χ_a of $(\text{NH}_4)_2\text{SO}_4$ were
224 larger than the value of 1.03 (Zelenyuk et al., 2006; Beranek et al., 2012; Zhang et al.,
225 2016a). However, previous studies found that the NaNO_3 particles had different
226 morphology. Zhang et al. (2016a) observed that NaNO_3 had the χ_a of 1.09-1.13,
227 indicating its asphericity, while Hoffman et al. (2004) found that NaNO_3 particle had a
228 round droplet-like shape even at 15% RH, which was supported by the consistence
229 between the measured value of “anhydrous” droplet density and the calculated value of
230 “anhydrous” solution droplet (Zelenyuk et al., 2005). Eclectically, Tang and
231 Munkelwitz (1994) studied that most of the NaNO_3 particles crystallized between 20%
232 and 30% RH but some persisted down to 10% RH to form solution droplets. Notably,

233 the spherical NaNO_3 particles at low RH observed by Hoffman et al. (2004) were dried
234 in the sticky carbon tape which might affect the phase transition of droplet-like NaNO_3
235 particles. In this study, most NaNO_3 particles were crystallized because the RH of the
236 aerosol flow carrying the NaNO_3 particles was reduced to below 20% through the
237 diffusion drying tube. Besides, the result that the crystallized NaNO_3 particles are
238 aspherical is supported by their FWHM values of the D_{va} distributions which are
239 consistent with that of aspherical $(\text{NH}_4)_2\text{SO}_4$ but different from spherical PSL (Figures
240 S1 and S2).

241

242 **3.3 Application of the AAC-SPAMS system for measuring the chemically-resolved**

243 **D_{ve} and ρ_e**

244 SPAMS can obtain information on the chemical composition of individual particles,
245 implying that the AAC-SPAMS system has the ability to simultaneously characterize
246 D_{ve} , ρ_e and the chemical compositions of particles in real time. It is worth noting that
247 the particles with the largest χ in the actual atmosphere should be freshly emitted soot,
248 which χ is 2.5 (Peng et al., 2016). This largest χ fitly meets the upper limit for the
249 approximation between the χ_t and χ_v (DeCarlo et al., 2004). Therefore, the AAC-SPAMS
250 system can obtain the chemically-resolved D_{ve} and ρ_e values for unknown aerosol
251 particles in the field observation.

252 As an example, we applied the AAC-SPAMS system to illustrate how the measured
253 D_a , D_{va} , and chemical composition of an individual particle can be used to calculate the
254 D_{ve} and ρ_e for unknown particles. The sampled $\sim 100,000$ particles are first classified by

255 using an adaptive resonance theory neural network (ART-2a) with a vigilance factor of
256 0.75, a learning rate of 0.05 and 20 iterations. The above system was used to cluster the
257 particles into eight major particle types with distinct chemical patterns of K-rich, EC-
258 S, K-Na, Amine, EC-N-S, OC-N-S and OC-EC-N-S and Metal-rich, representing 97%
259 of the detected particle population. Details of the chemical composition and number
260 fraction of the eight types of particles are provided in the Supporting Information.

261 We used Gaussian fitting to obtain the D_{va} peaks for each particle type with D_a values
262 of 250.0 nm, 350.0 nm, 450.0 nm, and 550.0 nm. Then, we calculated the D_{ve} values of
263 the atmospheric particles with Eq. (11). Table 1 presents the average D_{ve} values of the
264 eight particle types, for which the standard deviation is calculated based on nine
265 samples. The average D_{ve} at D_a values of 250.0 nm, 350.0 nm, 450.0 nm, and 550.0 nm
266 has the following wide ranges: from 188.5 nm to 200.8 nm, 271.9 nm to 295.7 nm,
267 342.5 nm to 428.9 nm, and 397.3 nm to 570.9 nm, respectively, which are caused by
268 the chemical composition differences. The result indicates that particles with
269 significantly different D_{ve} might possess the same D_a . Furthermore, the large standard
270 deviation of D_{ve} , such as 21.9 nm for K-Na at 250.0 nm, 32.3 nm for OC-EC-N-S at
271 350.0 nm, and 44.3 nm for OC-N-S at 450.0 nm, indicates that the D_{ve} of particles is
272 remarkably different even for particles with the same type and same D_a .

273 According to D_{ve} and D_{va} , we calculated the ρ_e of each particle type with Eq. (12).
274 Figure 4 shows the variations of the ρ_e with D_{ve} for nine particle samples. For pure
275 compounds, such as $(\text{NH}_4)_2\text{SO}_4$ and NaNO_3 particle, ρ_e theoretically does not change
276 with particle size. However, the sampled particles have experienced complex

277 atmospheric processes. Therefore, ρ_e has a very wide distribution for each type of
278 particle with a similar D_{ve} . Specifically, the ρ_e of K-Na increases with D_{ve} , while the ρ_e
279 of OC-N-S and OC-EC-N-S decreases with D_{ve} , which may be influenced by the
280 particle shape. Additionally, the average ρ_e of each type of particle is in the order from
281 small to large: $1.21 \pm 0.20 \text{ g/cm}^3$ for OC-EC-N-S, $1.25 \pm 0.15 \text{ g/cm}^3$ for OC-N-S, 1.45
282 $\pm 0.06 \text{ g/cm}^3$ for K-rich, $1.45 \pm 0.04 \text{ g/cm}^3$ for Amine, $1.46 \pm 0.05 \text{ g/cm}^3$ for EC-N-S,
283 $1.47 \pm 0.02 \text{ g/cm}^3$ for EC-S, $1.55 \pm 0.09 \text{ g/cm}^3$ for K-Na and $1.56 \pm 0.08 \text{ g/cm}^3$ for
284 Metal-rich. It is reasonable to find that the average ρ_e of internally mixed particles
285 distributes in the range of their material densities (ρ_m). For instance, mainly comprised
286 of internally mixed sulfate and organics, the OC-EC-N-S, OC-N-S, K-rich, and Amine
287 particles have the average ρ_e between that of sulfate with ρ_m of 1.77 g/cm^3 and organic
288 aerosols with ρ_m of 1.2 g/cm^3 (Cross et al., 2007).

289

290 4. Conclusion

291 We first develop an AAC-SPAMS system to achieve the measurement of the D_{ve} and
292 ρ_e of the particles through characterizing their D_a and D_{va} . The reliability of the AAC-
293 SPAMS system is verified by accurately measuring the D_{ve} and ρ_e of PSL. Applying the
294 AAC-SPAMS system to determine the D_{ve} and ρ_e of $(\text{NH}_4)_2\text{SO}_4$ and NaNO_3 particles
295 shows that these particles are aspherical and their ρ_e are independent of particle size.
296 Coupled with the ability of SPAMS to characterize the chemical composition of
297 individual particles, we conducted a sample proof of the AAC-SPAMS equipment in
298 Guangzhou to first characterize the D_{ve} , ρ_e and chemical compositions of atmospheric

299 particles, showing the potential application of this system in field observations. The
300 approach achieves the measurement of chemically-resolved D_{ve} and ρ_e , and provides
301 the possibility to determine their quantitative relationship with other particle properties,
302 which would be benefit for further reduction of the uncertainty associated with the
303 effects of particles on air quality, human health and radiative forcing.

304

305 **Data availability.** Data in this study is available at [https://github.com/longer1217/All-](https://github.com/longer1217/All-figures-data)
306 [figures-data](https://github.com/longer1217/All-figures-data).

307

308 **Author contributions.** The idea for the study was conceived by LP and GHZ. All
309 experiments were performed by LP with the assistance of LL. LP wrote the paper which
310 was reviewed by GHZ and XHB. All co-authors discussed the results and commented
311 on the manuscript.

312

313 **Competing interests.** The authors declare they have no conflict of interest.

314

315 **Acknowledgment**

316 This work was supported by the National Nature Science Foundation of China
317 (41775124 and 41877307), Natural Science Foundation of Guangdong Province
318 (2019B151502022), and the Guangdong Foundation for the Program of Science and
319 Technology Research (2019B121205006 and 2017B030314057). The authors also
320 gratefully acknowledge Cambustion Ltd., UK for providing the AAC and Hexin

321 Analytical Instrument Co., Ltd., China for providing the SPAMS.
