25 1 Introduction

The texts, figures and tables provide additional information that will help in our understanding of the model configuration, model evaluation and HPE identification and characterization.

1.1 Details of WRF model configurations

Figure S1. (a) WRF-Chem simulation domains. Downscaling was performed from D1 (27 km), D2 (9 km), and then D3 (3 km). (b) The study area and the location of all the stations for meteorology observations. More information about the stations is presented in section 2.

Figure S2. WRF Domain 3 USGS LULC configuration. USGS categorizations are named as follows: 1 Urban and Built-Up; 2 Dryland, Cropland, and Pasture; 3 Irrigated Cropland and Pasture; 4 Mixed Cropland and Pasture; 5 Cropland/Grassland

40 Mosaic; 6 Cropland/Woodland Mosaic; 7 Grassland; 8 Shrubland; 9 Mixed Shrubland/Grassland; 10 Savanna; 11 Deciduous Broadleaf; 12 Deciduous Needleleaf; 13 Evergreen Broadleaf; 14 Evergreen Needleleaf; 15 Mixed Forest; 16 Water Bodies; 17 Herbaceous Wetland; 18 Wooded Wetland; 19 Barren/Sparsely Vegetated; 20 Herbaceous Tundra; 21 Wooded Tundra; 22 Mixed Tundra; 23 Bare Ground Tundra; 24 Snow or Ice.

|--|

Configurations	Physics scheme options
Microphysics	Morrison 2-Moment Scheme
Longwave Radiation	RRTMG Longwave Scheme
Shortwave Radiation	RRTMG shortwave Scheme
Surface Layer	MM5 Similarity Scheme
Land Surface	Unified Noah Land Surface Model
Planetary Boundary Layer	YSU
Cumulus	Grell 3D Scheme

In the innermost model domain (Figure S1a), the urban areas were also found to aggregate toward each other and comprised 11 cities located in the PRD region (Figure S1b: Guangzhou, Shenzhen, Foshan, Dongguan, Zhongshan, Zhuhai, Huizhou, Jiangmen, Zhaoqing, Hong Kong, and Macau. Table S1 shows the physics schemes used in the model simulations. The chemical mechanism option was set as CB05 and a MADE/SORGAM_aq aerosol model was used. The USGS land use/land

50

cover categorization from WRF was used to delineate between urban/built-up and vegetated areas. The urban and built-up category was used to represent urban surfaces and the vegetated category represented all other surfaces besides urban and water categories (Figure S2). The data shows that about 15% and 70% of the domain was designated as built-up and vegetated land use, respectively.

2 Model Evaluation

60 2.1 Evaluation method

The results from the baseline model simulations were compared with observations from stations within the PRD region (Figure S1b; 16 stations for meteorology and 11 for air quality). Metrics used to validate the performance of the model included correlation coefficients (r), mean bias (MB), and root mean squared error (RMSE), the mathematical expressions for which are

65

$$\mathbf{r} = \frac{\sum_{i=1}^{N} (M_i - \overline{M}) (\boldsymbol{o}_i - \overline{\boldsymbol{o}})}{\left\{\sum_{i=1}^{N} (M_i - \overline{M})^2 \sum_{i=1}^{N} (\boldsymbol{o}_i - \overline{\boldsymbol{o}})^2\right\}^{1/2}},\tag{1}$$

$$MB = \frac{1}{N} + \sum_{i=1}^{N} (M_i - O_i) = \overline{M} - \overline{O},$$
⁽²⁾

70
$$RSME = \frac{1}{M} \sum_{j=1}^{M} \left[\frac{1}{N} \sum_{i=1}^{N} (\boldsymbol{O}_{i} - \overline{\boldsymbol{O}})^{2} \right]^{1/2},$$
(3)

where M_i and O_i are values of the model and observation results at hour *i*, respectively; *N* is the number of samples (hours) for each time and location; and \overline{M} and \overline{O} are model and observation means, respectively.

2.2 Observational Data for HPE Identification

- 75 Hourly air temperature, relative humidity, and wind speed data were obtained from the Hong Kong Observatory station (22°18'0''N, 114°10'2''E). One station was used for temperature due to the minor spatial variability in temperature. The hourly data for O₃ and PM₁₀ used for HPE identification were obtained from 14 air quality stations within Hong Kong. These were operated by the Hong Kong Environmental Protection Department during the study period. Hong Kong air quality stations were used as proxies to identify HPEs in the PRD region because there was insufficient data for the stations in the region during the study period. The PRD regional air quality monitoring network's annual and quarterly report between 2013–2018
- showed that air quality in Hong Kong was always better than or similar to the other stations in the region (Anon, 2019).

2.3 Model performance

85

Table S2a. Model evaluation for mean air temperature at 2 m (T_2), wind speed at 10 m (WS_{10}), and relative humidity at 2 m (RH_2) for all eight HPEs and 16 stations. RMSE, root mean square error, MB, mean bias; MNB, mean normalized bias; NMB, normalized mean bias, MFB- mean fractional bias.

Statistical Variables	T2 (°C)	WS ₁₀ (m/s)	$\mathrm{RH}_{2}(\%)$
Model Mean	28.31	4.23	76.57

28.08	3.40	75.67
0.70	0.33	0.64
1.94	2.67	10.25
0.25	0.86	-1.07
1.50	201.16	-0.22
1.26	54.64	-1.03
1.18	36.76	-1.22
	28.08 0.70 1.94 0.25 1.50 1.26 1.18	28.08 3.40 0.70 0.33 1.94 2.67 0.25 0.86 1.50 201.16 1.26 54.64 1.18 36.76

Table S2 shows the results for model evaluation. The simulated means of all the variables were consistent with the observed means. Strong correlations were found between model results and observations for T_2 and RH_2 with correlation coefficients of 0.70 and 0.64, respectively. The MB and RMSE for T_2 were 0.25°C and 1.94°C, respectively. For RH₂, MB and RMSE were

90 -1.07% and 10.25%, respectively. The correlation coefficient for wind speed was approximately 0.33, whereas the MB and RMSE were 0.86 and 2.67 m/s, respectively. These results indicate an overestimation of surface wind speeds in the WRF model, which is reported to be a common problem in regional meteorological modelling (Fan et al., 2011). A possible reason for this is that the observations represent wind speed at one local point, whereas the results for the model represent an average quantity over a model grid. The T₂ and RH results indicate good agreement between the simulated results and the observations.
 95 Overall, the evaluation results show that the WRF model was sufficiently robust for this study.

Table S2b. Model evaluation for mean PM_{2.5}, PM₁₀, Ozone (O₃), Nitrogen di oxide (NO₂), and Sulfur di oxide (SO₂) for all eight HPEs and 11 stations. RSME, root square mean error, mean bias; Model mean; Observation (Obs) Mean; Index of Agreement.

Statistical Variables	PM _{2.5}	PM_{10}	O ₃	NO ₂	SO_2
Model mean	15.5	28.0	37.3	37.4	15.5
Obs Mean	32.0	44.3	46.5	50.5	14.6
Index of Agreement	0.5	0.5	0.6	0.6	0.6
RSME	23.8	27.5	46.7	31.3	15.3
Mean Bias	-17.6	-16.3	-4.8	-8.1	0.9

The air quality evaluation was conducted for $PM_{2.5}$, PM_{10} , O_3 , NO_2 and SO_2 . The mean result from the 11 stations and 8 HPEs studied shows that the index of agreement was 0.5 and 0.6 for the particulates and gaseous, respectively. The mean bias for the particulates were -17.6 µg/m³ (PM_{2.5}) and -16.3 µg/m³ (PM₁₀), while the gases were -4.8 µg/m³ (O_3), -8.1 µg/m³ (NO_2) and 0.9 µg/m³ (SO_2). The underestimation observed for the particulates can be attributed to the overestimation of wind speed which can result in increased dispersion and lowering of concentrations.

3 HPE identification

- 105 50th percentiles were selected based on a number of factors. The first factor was that the 50th percentile of temperature exceeds the critical temperature above which risks of health impact were significant (Chan et al., 2012; Wang et al., 2019). The air quality was considered adequate because the PM_{10} and O_3 thresholds exceed the WHO acceptable annual and daily (Anon, 2006). Also, one station was used for temperature due to the rather small spatial variability in temperature. The temperature bias between the selected station and other non-urban stations within the region was ± 0.5 °C, hence one station was considered
- 110 adequate.

We performed a sensitivity test and found that if the threshold values are set too high, too few number of cases can be identified and make our analysis difficult. In the contrast, if the threshold values are set too low, too many cases would be identified. After balancing the above factors, 50th percentile was selected.

Threshold		Mean PM ₁₀	Mean O ₃	
Values	$T_2^{\circ}C$	$(\mu g/m^3)$	$(\mu g/m^3)$	# of HPEs
50%	31.3	31.1	24.5	8
60%	31.8	36.3	32.1	6
70%	32.3	44.9	40.6	2
80%	32.7	56.5	50.4	1
90%	33.12	71.46	63.13	0

Table S3. Sensitivity test for the total number of HPEs for the study period

4 Identified HPEs

HPE Year S	Start	Start		End		Crown	
	Month	Day	Month	Day	No. of days	Group	
1	2009	8	1	8	3	3	TC
2		8	30	9	10	12	ST
3		9	19	9	21	3	HY
4		9	23	9	26	4	HY
5	2010	8	4	8	7	4	ST
6		8	29	9	1	4	TC
7	2011	8	26	8	30	5	TC
8		9	7	9	10	4	HY

Table S4. HPEs for the study period. Eight HPEs were identified and classified into three HPE groups: Stagnant (ST); Tropical cyclone (TC), and Hybrid (HY).

Figure S3. (a) Air temperature at 2 m (T_2). (b) Specific humidity. (c) Sea level pressure. (d) Geopotential Height. Diurnal means are for the three clusters for TC (blue lines), ST (red lines), and HY (brown lines) group.

The results of the cluster analysis indicate that eight HPEs can be classified based on their formation and characteristics: 135 Tropical Cyclone (TC-HPE); Stagnant (ST-HPE); and Hybrid (HY-HPE). Figure S3 showed the diurnal means of T₂, specific humidity, Sea Level Pressure (SLP), and geopotential height of the three HPE groups. Particularly, the HPEs in each group did not vary significantly, whereas remarkable differences were found in T₂ among the three groups. The TC-HPE had the highest temperature (32 °C) during its peak period, followed closely by the peak of ST-HPE (31 °C) and HY-HPE (29 °C), which typically occurred at 14:00 local time. Among the three groups, TC-HPE had a relatively lower SLP (~999 hPa) and 140 geopotential height (GPH, 5,855 m), whereas for ST-HPE and HY-HPE, these values were respectively approximately 1,005 hPa and 5,875 m and approximately 1,009 hPa and 5,895 m (Figure S3c-d).

Figure S4: Tropical cyclone group Episode (20100829-0901) Shows the evolution of the temperature and pressure conditions during the TC-HPE. The weather charts were obtained from the Hong Kong Observatory web site (<u>https://www.hko.gov.hk/en/wxinfo/currwx/wxcht.htm</u>) on may. 2018.

Figure S5: Stagnant group Episode (20100804-07) Shows the evolution of the temperature and pressure conditions during the ST-HPE. The weather charts were obtained from the Hong Kong Observatory web site (https://www.hko.gov.hk/en/wxinfo/currwx/wxcht.htm) on may. 2018.

Figure S6. Hybrid group Episode (20110907-10) Shows the evolution of the temperature and pressure conditions during the 160 HY-HPE. The weather charts obtained were from the Hong Kong Observatory web site (https://www.hko.gov.hk/en/wxinfo/currwx/wxcht.htm) on may. 2018.

6 Simulated Wind profiles for the HPE groups

Figure S7. (a-c) Wind speed(m/s) for TC-HPE, ST-HPE and HY-HPE; (d-f) Wind direction for TC-HPE, ST-HPE and HY-HPE. Black boxes represent the period of HPEs.
