

# ***Interactive comment on “Production of HONO from heterogeneous uptake of NO<sub>2</sub> on illuminated TiO<sub>2</sub> aerosols measured by Photo-Fragmentation Laser Induced Fluorescence” by Joanna E. Dyson et al.***

## **Anonymous Referee #1**

Received and published: 3 January 2021

In this study the authors used an aerosol flow tube reactor connected to a photo-fragmentation laser induced fluorescence detection set-up to evaluate the heterogeneous chemistry of NO<sub>2</sub> with irradiated TiO<sub>2</sub> aerosols. The uptake coefficients of NO<sub>2</sub> were determined for NO<sub>2</sub> mixing ratios ranging between 34 and 400 ppb. The HONO production was determined as well at different relative humidities (RH), the highest being at 25 % RH. The performed kinetic box model suggested HONO production by heterogeneous reaction of NO<sub>2</sub> with TiO<sub>2</sub> aerosol surface involving two NO<sub>2</sub> molecules, and a HONO loss which is dependent on the initial NO<sub>2</sub> mixing ratio. Discussion paper

iments have shown that HONO is also formed upon irradiation of mixed nitrate/TiO<sub>2</sub> aerosols in the absence of NO<sub>2</sub>. This is an interesting study following the continuation of a number of previous studies focused on this topic. The experiments are well performed and the kinetic box model was used to support the experimental results. I would suggest publication of this study in Atmospheric Chemistry and Physics as it can be of broad interest for the atmospheric chemistry community.

1) The photo-fragmentation laser induced fluorescence detection apparatus seems promising tool for online measurements of HONO in ambient air. However, the only reference about this instrument is the thesis of Boustead (2019) which is not easily accessible. I wonder if this instrument was previously used in an intercomparison campaign against other well established instruments for real time HONO measurements (e.g. DOAS, LOPAP).

2) The authors observed HONO formation upon irradiation of mixed nitrate/TiO<sub>2</sub> aerosols and pure nitrate aerosols but they did not mention in the manuscript whether or not HONO is formed only upon irradiation of TiO<sub>2</sub> aerosols in absence of NO<sub>2</sub>. These tests should be carried out as control experiments.

3) The authors mentioned that the aqueous solutions ready to be dispersed in the air, were obtained by dissolving 5 g of TiO<sub>2</sub>, but they did not mention the quantity of dissolved ammonium nitrate in the solution. How relevant is this amount of TiO<sub>2</sub> dissolved in water?

4) Another very important point is that many papers related to NO<sub>2</sub> heterogeneous chemistry on TiO<sub>2</sub> as a HONO source are not cited and discussed. For example, Gandolfo et al (Appl. Catal. B: Environ., 2015, 166-167, 84-90; Appl. Catal. B: Environ., 2017, 209, 429-436) have shown that the disproportionation reaction of NO<sub>2</sub>, which has been also suggested as a night-time source of HONO in the atmosphere, can be photocatalytically enhanced in the presence of TiO<sub>2</sub> which is in agreement with the statement in this study that two NO<sub>2</sub> molecules forming HONO are required

to reproduce the experimental trend of the uptake coefficients and observed HONO concentrations. Furthermore, a similar profile of the observed dependence of HONO mixing ratios with the RH was also observed by Gandolfo et al. (2015) by detecting a maximum of HONO at 30 % RH as was measured in this study. Increase of HONO with RH on building surface containing TiO<sub>2</sub> was also observed by Langridge et al (Atmospheric Environment 43 (2009) 5128-5131).
