Abstract: Ozone (O_3) pollution is of great concern in the Yangtze River Delta (YRD) region of China, and the regional O_3 pollution is closely associated with dominant weather systems. With a focus on the warm seasons (April–September) from 2014 to 2018, we quantitatively analyze the characteristics of O_3 variations over the YRD, the impacts of large-scale and synoptic-scale circulations on the O_3 variations and the associated meteorological controlling factors, based on observed ground-level O_3 and meteorological data. Our analysis suggests an increasing trend of the regional mean O_3 concentration in the YRD at 1.81 ppb per year over 2014–2018. Spatially, the empirical orthogonal function ~~(EOF)~~ analysis suggests the dominant mode accounting for 65.70% variation in O_3, implying that an increase in O_3 is the dominant tendency in the entire YRD. Meteorology is estimated to increase the regional mean O_3 concentration by 3.03~~2.81~~ ppb at most from 2014 to 2018. Especially, compared to solar radiation (SR) and low cloud cover (LCC) of relatively large impacting on O_3 variation, relative humidity (RH) plays the most important role in modulating the inter-annual O_3 variation ~~Relative humidity is found to be the most influential meteorological factor impacting O_3 concentration~~. As ~~the~~ atmospheric circulations can affect local

meteorological factors and O_3 levels, we identify five dominant synoptic weather patterns (SWPs) in the warm seasons in the YRD using the t-mode principal component analysis (PTT) classification. The typical weather systems of SWPs include the western Pacific Subtropical High (WPSH) under SWP1, a continental high under SWP2, an extratropical cyclone under SWP3, a southern low pressure and WPSH under SWP4 and the north China anticyclone under SWP5. The annual variations of theall five SWPs are all favorable to the increase in O_3 concentrations over 2014–-2018. However, crucial meteorological factors leading to increases ineausing increasing of O_3 concentrations are different under differenteach SWP. These factors are identified as , including significant decreases inly decreasing relative humidityRH and increases in, strengthening SRsolar radiation under SWPs 1, SWP4 and SWP5, significant decreases ining RH, increases instrengthening SR and increasing air temperature (T2) under SWP2, and significant decreases ining RH under SWP3. Under SWPs 1, 4 and 5, significant decreases inly decreasing RH and increases instrengthening SR are predominantly caused by the WPSH weakening and northward extending under SWP1, the southern low pressure weakening and the WPSH weakening under SWP4, and the north China anticyclone weakening under SWP5. Under SWP2, significant decreases inly decreasing RH, increases instrengthening SR and increasing T2 are mainly chiefly producecauseproduced by a continental high weakening. Under SWP3, significantly decreasing RH is mainly induced by an extratropical cyclone strengthening. These changes in atmospheric circulations prevent the water vapor in the southern and northern sea from being transported to the YRD and result in RH sSignificantly decreasing under each SWP. In addition, strengtheneding descending motions (behind the strengthening trough and in front of the strengthening ridge) lead to decreases ining LCC and sSignificantly strengthening SR under SWP1, 2, 4 and 5. The sSignificantly increases ining T2 would be due to weakening cold flow introduced by a weakening continental high. Moreover,Most importantly, the the these changes in in the SWP intensity can make large variations ineausing significant meteorological factors and contribute more variatio n take more contributionses more to the O_3 inter-annual variation than the variation in the SWP frequency change. The SWP intensity change includes the weakening and northward extending of the western Pacific subtropical high (WPSH) under SWP1, the weakening of the continental high under SWP2, an extratropical cyclone strengthening under SWP3, the southern low pressure

带格式的: 非突出显示

~~weakening and WPSH weakening under SWP4, and the north China anticyclone weakening under SWP5. All these changes prevent the water vapor in the southern sea from being transported to the YRD, and increase air temperature in the YRD. In addition, the descending motions strengthen in the YRD located behind the trough and in front of the ridge due to the strengthening of the ridge and trough in the westerlies. Then, the strengthened descending motion leads to less cloud cover and strong solar radiation, which are favorable to O_3 formation and accumulation.~~ Finally, we reconstruct an EOF mode 1 time series that is ~~shows~~ highly correlated~~ion~~ with the original O_3 time series, and the reconstructed time series performs well in defining the change in SWP intensity according to the unique feature under each of the SWPs.

1. Introduction

As an air pollutant, surface ozone (O_3) is harmful to human health and vegetation growth, such as damaging human lungs (Jerrett et al. 2009; Day et al. 2017) and destroying forest and agricultural crops (Yue et al. 2017). A~~In recent years, a~~fter the ~~reducing the~~ emission control~~s~~ following "Thirteenth Five-Year Plan" Comprehensive Work Plan for Energy Saving and Emission Reduction in China since 2016, concentrations of many pollutants have decreased over the past few years in China, but not for O_3. Furthermore, heavy O_3 pollution episodes~~s~~ occur more frequently and more severely in China than ~~those~~ in Japan, South Korea, ~~Europe and~~ the United States, and the European countries ~~–~~(Lu et al. 2018). Li et al. (2018) proposed that the rapid decrease of fine particulate matter (PM) in China is a reason for such O_3 increase as~~by slowing down the~~ aerosol sinks of hydro-preoxy radicals are reduced. Yet, ~~the contribution of~~ meteorological influences on~~factors to~~ the O_3 increase are~~is~~ unclear and require ~~needs~~ further investigations.

Surface O_3 is mainly formed through complex and nonlinear photochemical reactions of volatile organic compounds (VOCs) and nitrogen oxides (NO_x) exposed to the sunlight~~. Ozone formation is sensitive to concentrations of NO_x and VOCs, i.e., O_3 formation can be NO_x-limited or VOC-limited regimes depending on concentrations of NO_x and VOCs~~ (Xie et al. 2014~~; Jin and Holloway 2015~~). Meteorology can~~ould also~~ affect O_3 levels through modulation of photochemical reactions, advection, convection and turbulent transport, as well as dry and wet depositions (Liu et al. 2013; Xie et al., 2016a, 2016b). Synoptic weather patterns (SWPs) and the associated meteorological conditions can impact long-term and daily O_3 variations (Hegarty et al.~~,~~ 2007; Santurtún et al.~~,~~ 2015;

带格式的: 字体颜色: 文字 1

Gao et al.~~,~~ 2020; Shu et al., 2020). Understanding the mechanisms of meteorological influences on O_3 variations and quantifying such influences would help ~~provide effective emission-controlling plans for~~to understand the formation of O_3 pollution.

Previous studies have revealed that ~~S~~severe O_3 pollution episodes are usually accompanied with ~~specific local meteorological conditions, such as~~ high temperature, strong solar radiation, drying condition and stagnant weather~~ etc.~~ (Jacob and Winner 2009; Doherty et al. 2013; Shu et al. 2016; Pu et al. 2017; Zhang et al. 2018), and~~.~~ ~~Moreover,~~these local meteorological conditions are often related to specific synoptic-scale and large-scale atmospheric circulation systems (Fiore et al. 2003; Leibensperger et al. 2008; Barnes and Fiore. 2013; Shu et al. 2016; Wang et al. 2016; Zhao and Wang. 2017 ~~文献~~). For example, O_3 pollution in the eastern United States is notably influenced by the cyclone frequency (Leibensperger et al. 2008), latitude of the polar jet over eastern North America (Barnes and Fiore. 2013) and the behavior of the quasi-permanent Bermuda High (Fiore et al. 2003;~~,~~ Wang et al. 2016). In China, Yang et al. (2014) illustrated that the changes in meteorological variable~~parameter~~s, associated with the East Asian summer monsoon, lead to 2–5 % inter-annual variations in surface O_3 concentrations over the central-eastern China. Zhao and Wang ~~et al.~~ (2017) found that a significantly strong western Pacific subtropical high (WPSH) could result in higher relative humidity (RH), more clouds, more rainfall, and less ultraviolet radiation, finally leading to less O_3 formation. Using model simulation, Shu et al. (2016) investigated the synergistical impact of the ~~the~~ WPSH and typhoons on O_3 ~~level~~pollution in Yangtze River Delta region.

As known, a region is influenced by different weather systems. Weather classification, as a way to distinguish the different large-scale and synoptic-scale atmospheric circulation systems, is widely used in exploring connections between weather patterns and O_3 levels (Han et al. 2020; Gao et al. 2020). Gao et al. (2020) discussed influences of six SWPs on O_3 levels in the YRD, and revealed differences in O_3 pollution levels due to~~ the~~ minor changes in atmospheric circulations. However, spatially, it is uncertain that how~~ the~~ changes in the SWPs could lead to O_3 pollution in detail, especially in the YRD. For the northern China and the PRD region, Liu et al. (2019) quantified the impact of synoptic circulation patterns on O_3 variability in the northern China from April to October during 2013–2017. Yang et al. (2019) quantitatively assessed the impacts of meteorological factors and the precursor emissions on the long-term trend of ambient O_3 over the PRD region. However~~Yet~~,

带格式的: 非突出显示

带格式的: 非突出显示

带格式的: 非突出显示

带格式的: 非突出显示

whether variations in SWPs can lead to O_3 increases in recent years over the YRD has not be sufficiently addressed.

Due to the recent increases in ever-growing O_3 level over in the YRD (Tong et al. 2017; Gao et al. 2017; Xie et al. 2017), the studies on characteristcharacterizing ies ofthe –O_3 variation in the region and understanding thethe underlying mechanisms for the variation are urgently required. To this end, here the temporal and spatial variations in surface O_3 including –variations in space and time, as well as 5-year trend over, in the YRD areis quantitatively investigated, and the mechanisms of meteorological influences on the O_3 variations are analyzed. Especially, the characteristics of the corresponding SWPs are discussed in detailed. The remainder of this paper is organized as follows. Data and methods are introduced in section 2. The inter-annual variation and 5-year trend and spatial variation characteristics of surface ozone in the YRD –are illustrated in section 3.1. The impact of meteorological factors on the O_3 variation is discussed in section 3.2. The main SWPs and the effects of their changes on the O_3 variation are described in section 3.3. Section 3.4 discusses the contributions of the changes in SWP intensity and frequency change to the inter-annual variation and trend of O_3. Finally, the conclusion and discussions are shown in section 4.

2. Data and methods

2.1. O_3 and meteorological datasets

The maximum daily 8-hours average O_3 data are available from the National Environmental Monitoring Center of China, which were acquired from the air quality real-time publishing platform (http://106.37.208.233:20035). The hourly observation data of meteorological factors including air temperature (T), RH and, wind speed (WS) and sunshine duration (SD) in the warm seasons from April to September over 2014–2018 were acquired from the National Meteorological Center of China Meteorological Administration (http://eng.nmc.cn). 26 cities are selected as typical cities representative of the YRD according to the “Urban agglomeration on Yangtze River Delta” approved by China’s State Council in 2016. There are total 172 stations in 26 cities. In order to better characterize the O_3 pollution levels of each city, the hourly O_3 concentration of each city is calculated as the average value of the O_3 concentrations measured in several of the national monitoring sites in that city. In this paper, the term "O_3 concentration" refers to the maximum daily 8-hours average O_3 concentration unless stated otherwise.

2.2. Linear trend analyses

T~~In order to~~ characterize the O_3 variation in the warm seasons during 2014–2018 over the YRD, a linear trend method based on monthly anomalies is used (see Equation 1), which has been widely used to calculate the trends of time series with seasonal cycles and autocorrelation.~~–~~ The O_3 monthly anomalies are more precise than O_3 monthly means because the impact of ~~of the reducing impact of~~ missing data is reduced. In addition, hourly O_3 data and fewer yearly O_3 data are inappropriate to use because of ~~due to the containing~~ too many temporal variation signals and easily overfitting. Using this method, Cooper et al. (2020) and Lu et al. (2020) quantified the O_3 trend in 27 globally distributed remote locations and the whole China. A~~In addition, a~~nomalies of monthly average O_3 concentration are defined as the difference between the individual monthly mean and the monthly mean of 2014–2018. The parametric linear trend is calculated by using the generalized least-squares method with auto-regression.

$$y_t = b + kt + \alpha \cos\left(\frac{2\pi M}{6}\right) + \beta \sin\left(\frac{2\pi M}{6}\right) + R_t \qquad (1),$$

where y_t represents the monthly anomaly, t is the monthly index from April to September during 2014–2018, b denotes the intercept, k is the linear trend, α and β are coefficients for a 6-month harmonic series (M ranges from 1 to 6) which is used to account for potentially remaining seasonal signals, and R_t represents a normal random error series. In this study, linear trend *k* is regarded as the inter-annual O_3 variation trend and is discussed in section 3.1.1.

2.3. Meteorological adjustment

The meteorological adjustment, a statistical method, is applied to quantify the impact of meteorology on O_3 variation through removing such impact in the original O_3 data. It is similar to a model simulation that keeps the emission levels fixed but allows meteorology to vary. Yet, this method requires much less computing resources than a model simulation. The method is introduced in detail as follows.

In the meteorological adjustment, the observed O_3 and meteorological data are separated into long-term, seasonal, and short-term data (Rao and Zurbenko 1994a, b). The Kolmogorov-Zurbenko (KZ) filter can be expressed as follows.

带格式的: 非突出显示

带格式的: 非突出显示

带格式的: 字体: 倾斜

$$R(t) = L(t) + S(t) + W(t) \quad (2),$$

where $R(t)$ represents the raw time series data, $L(t)$ the long-term trend on a timescale of years, $S(t)$ the seasonal variation on a timescale of months, and $W(t)$ the short-term component on a timescale of days.

In order to remove the high-pass signal, the KZ filter carries out *p* times of iterations of a moving average with the window length *m*, which is defined as

$$Y_i = \frac{1}{m}\sum_{j=-k}^{k} R_{i+j} \quad (3)$$

where *R* is the original time series, *i* an index for the time of iteration, *j* an index for sampling inside the window, and *k* the number of sampling on one side of the window. The window length $m = 2k + 1$. *Y* is the input time series after one iteration. Different scales of motions are obtained by changing the window length and the number of iterations (Milanchus et al. 1998; Eskridge et al. 1997). The filter periods of less than N days can be calculated with window length m and the number of iteration p, as follows:

$$\mathrm{m} \times p^{\frac{1}{2}} \le N \quad (4).$$

Therefore, the cycles of 33 days can be removed by a KZ-(15, 5) filter with the window length of 15 and 5 iterations. In Ethe following equation 5, BL(t) is the O_3 and meteorological time series obtained by KZ(15,5) filter and refers to their baseline variations which are the sum of the long term L(t) and the seasonal component S(t)..

$$BL(t) = KZ_{(15,5)} = L(t) + S(t) = KZ_{(183,3)} + S(t) \quad (5).$$

The long-term trend is separated from the raw data obtained by KZ (183, 3) with the periods of > 632 days, and then the seasonal and the short-term component $W(t)$ can be defined as

$$S(t) = KZ_{(15,5)} - KZ_{(183,3)} \quad (6),$$

$$W(t) = \mathrm{X(t)} - \mathrm{BL(t)} = \mathrm{X(t)} - KZ_{(15,5)} \quad (7).$$

After KZ filtering, the meteorological adjustment is conducted by the multivariate regression between the O_3 concentration and meteorological factors such as T, RH, wind speed and sunshine duration (Wise and Comrie 2005; Papanastasiou et al. 2012).

$$A_{BL}(t) = a_{BL} + \sum b_{BLi} \cdot M_{BLi} + \epsilon_{BL}(t) \quad (8),$$

$$A_W(t) = a_W + \sum b_{Wi} \cdot M_{Wi} + \epsilon_W(t) \quad (9),$$

$$\epsilon(\mathrm{t}) = \epsilon_{BL}(t) + \epsilon_W(t) \quad (10),$$

$$A_{ad}(t) = \epsilon(t) + \sum b_{BLi} \cdot \overline{M}_{BLi} + \sum b_{Wi} \cdot \overline{M}_{Wi} + a_{BL} + a_W \qquad (11).$$

the multivariate regression models between baseline and short-term O_3 and meteorological factors are shown in E~~e~~quations 8 and 9. The $A_{BL}(t)$ and M_{BLi} represent the sum of the long term L(t) and the seasonal component S(t) of O_3 concentration and meteorological factors. The $A_W(t)$ and M_{Wi} represent the short-term W(t) of O_3 concentration and meteorological factors. The a and b are the fitted parameters, and i is time point (days). $\epsilon(t)$ is the residual term. The average meteorological condition $\overline{M}$ at the same calendar date during the 5 years is regarded as the base condition for that date, and the meteorological adjustment is conducted against the base condition. In~~By~~ these steps, $A_{ad}(t)$ refers to the meteorologically adjusted O_3 variation with the homogenized annual variation in meteorological conditions. The difference between raw O_3 time series and $A_{ad}(t)$ represents the meteorological impact.

带格式的: 非突出显示

2.4. Classification of SWPs

In order to find the detailed variation characteristics of SWPs, we first extract the predominant SWPs in the warm seasons over the YRD using a weather classification method. Common objective classification methods include using predefined type, the leader algorithm, the cluster analysis, optimization algorithms and eigenvectors (Philipp et al. 2016). The PTT method, a simplified variant of t-mode principal component analysis using orthogonal rotation, is used to classify SWPs during 2014–2018. It is one of the methods for weather classification in European Cooperation in Science and Technology Action 733 (Philipp et al. 2016), which is widely used in atmospheric sciences (Hou et al. 2019).

2.5. FNL and ERA-Interim meteorological data

The National Center for Environmental Prediction Final Operational Global Analysis (FNL) data (http://rda.ucar.edu/datasets/ds083.2/) produced by the Global Data Assimilation System are used in classifying SWPs and analyzing atmospheric circulations. The data have a horizontal resolution of 2.5°×2.5°, with 144×73 horizontal grids available every 6 hours. From the near surface layer to 10 hPa, there are 17 pressure levels in the vertical direction. The data of the geopotential height and wind at 500 hPa and 850 hPa, the vertical wind (Ω), T and RH are used in this study. At the same time, the low~~total~~ cloud cover (L~~T~~CC), the total cloud liquid water (TCLW) and solar radiation (SR) from ERA-interim are supplemented in this study, which have the same temporal and spatial resolutions as the FNL data. Moreover, the western Pacific subtropical high index (WPSHI) and the eastern Asian summer monsoon index (EASMI) are calculated using the FNL data of the geopotential height and wind at 850 hPa. The WPSHI is defined following the~~according to~~ western Pacific subtropical high intensity index in the National Climate Center of China.~~,~~ Specific formula refers to website (https://cmdp.ncc-cma.net/extreme/floods.php?product=floods_diag). The EASMI is a shear vorticity index. It is defined as the difference of regional mean zonal wind at 850 hPa between 5 and 15°N, 22.5 and 32.5°N, 90 and 130°E, and 110 and 140°E in Wang and Fan (1999), recommended by Wang et al. (2008).

The FNL geopotential height field at 850 hPa can capture the synoptic circulation variations over the YRD well (Shu et al. 2017). In this study, we use the geopotential height at 850 hPa from April to September during 2014–2018 as the input for the PTT. WPSHI and EASMI are correlated ~~discussed the correlations~~ with the O_3 time series. W~~Besides, when we~~ used the Pearson correlation coefficient to calculate the correlations between two time series~~, Pearson correlation coefficient is as the only method to be used~~.

2.6. Reconstruction of O_3 concentration based on SWP

To quantify the inter-annual variability captured by the variations (frequency and intensity) in the synoptic weather patterns, Yaranl (1992) provided an algorithm to find the contribution of SWP frequency variation to the inter-annual O_3 variation. The specific calculation is as follows.

$$\overline{\overline{O_{3m}}}(fre) = \sum_{k=1}^{6} \overline{O_{3k}} F_{km} \quad (12),$$

where $\overline{\overline{O_{3m}}}(fre)$ is the reconstructed mean O_3 concentration influenced by the frequency variation in SWPs from April to September for year m, $\overline{O_{3k}}$ is the 5-year mean O_3 concentration for SWP k, and F_{km} is the occurrence frequency of SWP k during April–September for year m.

~~–~~Hegarty et al. (2007) suggested that changes in the SWP include both frequency change and intensity change. The intensity of SWPs represents the location and strength of the weather system. Moreover, they noted that the environmental and climate-related contributions to the inter-annual variations of O_3 could be better separated by considering these two changes. So, Equation12 is

域代码已更改

带格式的: 字体颜色: 文字 1

modified into the following form.

$$\overline{O_{3m}}(fre + int) = \sum_{k=1}^{6}(\overline{O_{3k}} + \Delta O_{3km})F_{km} \qquad (13),$$

where $\overline{O_{3m}}(fre + int)$ is the reconstructed average O_3 concentration influenced by the frequency and intensity changes of SWPs from April to September for year m; ΔO_{3km} is the modified difference on the fitting line, which is obtained through a linear fitting of the annual O_3 concentration anomalies (ΔO_3) to the SWP intensity index (SWPII) for SWP k in year m. ΔO_{3km} represents the part of the annual observed O_3 oscillation caused by the intensity variation in each SWP. Hegarty et al. (2007) used the domain averaged sea level pressure to represent the circulation intensity index (CII). Liu et al. (2019) reconstructed the inter-annual O_3 level in the northern China using the center pressure of the lowest pressure system. However, ~~But~~ we find the intensity variation in each SWP is different when O_3 increases. So we select different SWPII under each SWP~~pattern~~ –according to the characteristics of high O_3 concentration. Lastly, we select the maximum height in zone-1 (25°N–40°N, 110°E–130°E), the maximum height in zone-2 (20°N–50°N, 90°E–140°E) and the mean height in zone-3 (10°N–40°N, 110°E–130°E). Especially, zones1, 2 and 3 were selected in term of location of dominated weather systems under each SWP. Detailed demonstration is introduced in section 3.5.

3. Results and discussion

3.1. Spatio-temporal variations of O_3 in the YRD region

3.1.1. Inter-annual variations of O_3

Fig. 1a shows the time series of the anomalies of the monthly mean O_3 concentration over the YRD from April to September during 2014–2018, as well as the corresponding linear fitting curve. Fig.~~ure~~ 1b shows the annual variation in the total number of days with O_3 concentration exceeding the national standard during the warm seasons over 2014-2018~~period~~. As shown in Fig. 1a, the monthly mean O_3 concentration in the warm seasons increases over 2014-2018, reaching the maximum of 37.44~~37.44~~ ppb in 2017 and maintaining at a high level in 2018. According to the generalized least-squares method with auto-regression in section 2.2, obtained fitting function is $y_t = -0.8076 + 0.0521t - 0.4824\cos\left(\frac{2\pi M}{6}\right) + 0.6646\sin\left(\frac{2\pi M}{6}\right) + R_t$. Specifically, 5.21% (1.81 ppb) of k value as the O_3 inter-annual variation shows a large increasing trend in the YRD~~O_3~~

~~concentration in the YRD shows a large increasing trend of 1.81 ppb (5.21%) per year~~, which is slightly higher than that in the entire China (5.00% per year, Lu et al. 2020). Meanwhile, the annual average days with O_3 exceeding the standard during the warm seasons also show an increasing trend, reaching a peak in 2017 and maintaining at a high level in 2018. In all, both means and extremes of O_3 concentration have increased over the YRD.

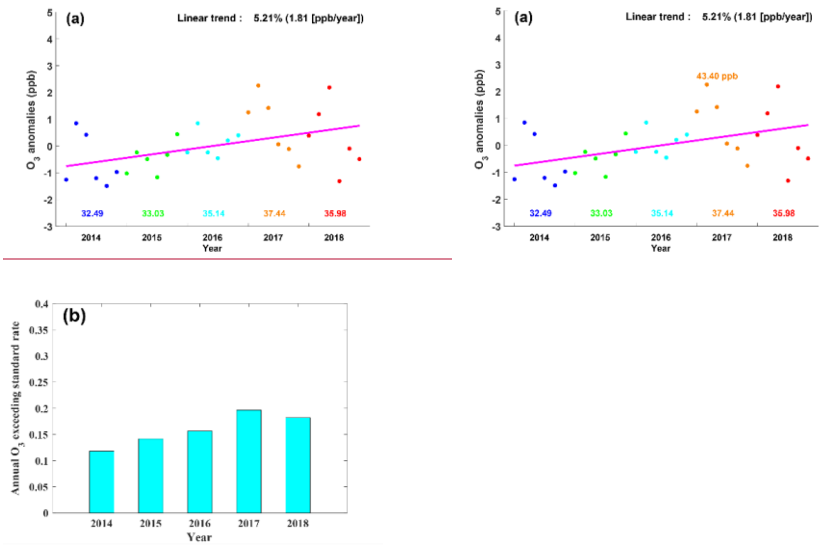

Fig. 1. (a) Anomalies of monthly average O_3 concentration from April to September during 2014–2018. The purple solid line represents the linear fitted curve $(y_t = -0.8076 + 0.0521t)$, and the color number represents the annual (April–September) mean of O_3 concentration. (b) Annual (April–September) variation in the days with O_3 exceeding the national standard.

3.1.2. Characteristics of O_3 variability based on the EOF analysis

To~~In order to~~ further discuss the spatio-temporal distribution characteristics of the observed O_3 concentration, the EOF approach is used to uncover the relationship between the spatial distribution and temporal variation. By removing the missing data for 17 days, O_3 concentrations in 898 days are processed. The percentages of variance contribution for the first three patterns are 65.70 %, 13.80 % and 9.10 %, respectively. The significance tests of the EOF eigenvalue confirm that the first three patterns are significantly separated. Approximately 88.60 % of the variability in the original data is contained in these three patterns. In the first EOF pattern (EOF1), the observed O_3 over the YRD changes similarly and the center of the variation is located in the middle of the YRD (Fig. 2a). As shown in Fig. 2b, the time series of EOF1 presents an increasing ~~decreasing~~ trend and shows a high negative correlation with the time series of O_3 (R = ~~−~~0.98~~3~~). Therefore, to some extent, the EOF1 time series variation can represent the daily mean O_3 variation and implies an increasing trend of regional mean O_3 concentration during these periods. ~~Considering the negative values in EOF1, the EOF1 time series implies an increasing trend of regional mean O_3 concentration.~~ Furthermore~~In addition~~, we investigated the relationships between the time series of EOF1 and different weather systems, as well as the meteorological factors ~~have been investigated~~. Weather systems include the WPSH and the East Asian summer monsoon, which are dominant weather systems affecting the YRD. Both of them show a poor correlation with the EOF1 time series (R_{WPSHI} = -0.13~~3~~ and R_{EASMI} = -0.04). It indicates that the daily O_3 variation is too complex to be comprehensively explained through the change in a single weather system. Furthermore, the RH and SR present~~s~~ a good correlation with the EOF1 time series (R_{RH} = -0.59 and R_{SR} = 0.56)~~. Han et al. (2020) also found that RH is the most important factor affecting O_3 in the YRD~~. However, it is still unclear how the change in different weather systems causes the variation in RH and SR, and how the variations in RH and SR ~~variation~~ impact~~s~~ the other meteorological factors and O_3 accumulation.

In the second EOF pattern (EOF2), there is obvious east-west contrast. In contrast, the third EOF (EOF3) pattern presents a notable south-north contrast. At the same time, the increasing trend of EOF2 time series and the decreasing trend of EOF3 time series indicate that O_3 concentrations in the west and northwest have risen from 2014 to 2018. It implies that a higher rate of O_3 increasing would occur in the northwest. As known, the variance contribution of EOF1 is 65.70 % that is greater than EOF2 (13.80 %) and EOF3 (9.10 %). Therefore, increases in ~~the~~ O_3 ~~increasing~~ in the entire ~~whole~~ YRD region is the main trend.

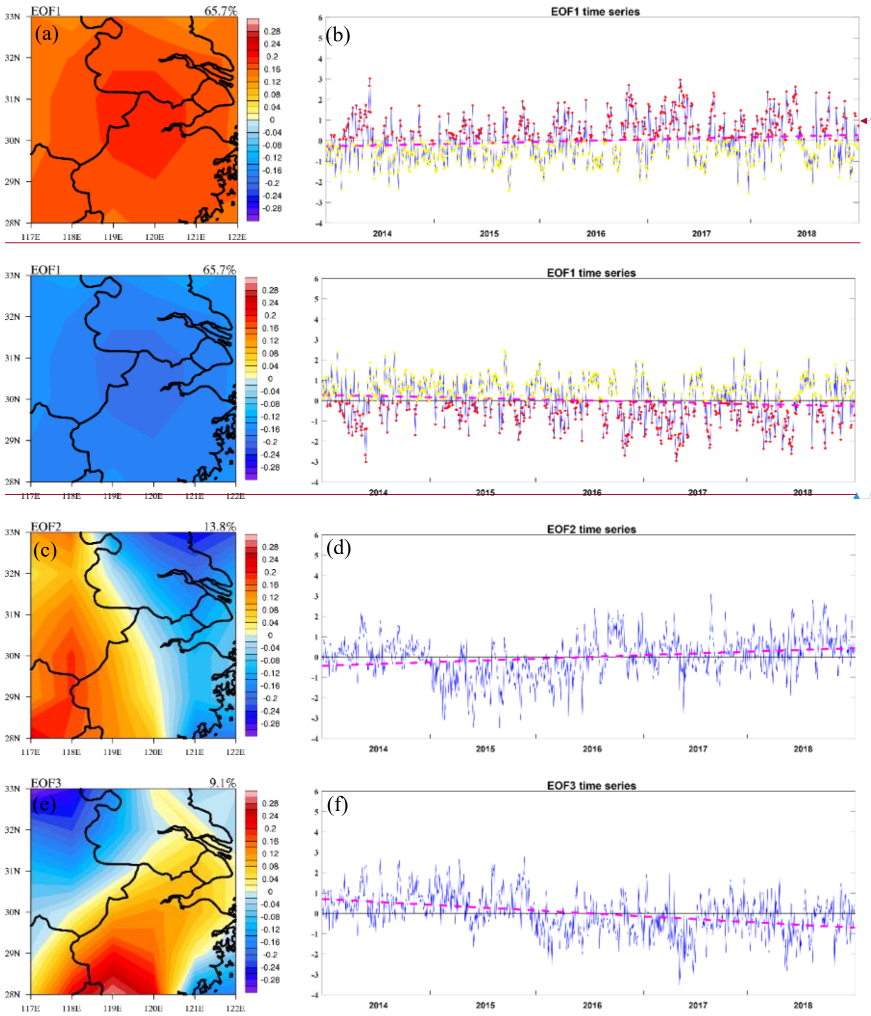

Fig. 2. Three EOF patterns of O_3 concentration in the warm seasons from 2014 to 2018, including the spatial pattern (a, c and e) and time coefficient (b, d and f). The percentage in panels (a, c and e) is the variance contribution of each EOF mode. The pink~~orange~~ dash line in panels (b, d and f) represents the linear fitted curve.

3.2. Effects of meteorological conditions on O_3 concentration over the YRD region

3.2.1. Quantifying the effects of meteorological conditions

With the primary pollutant emissions being cut down, the surface O_3 increase in the recent years

带格式的: 行距: 单倍行距

带格式的: 字体颜色: 蓝色

in China might be attributable to~~affected by~~ a variety of factors, one of which was suggested to be the slowing down sink of hydroperoxy radicals, related to the variation in $PM_{2.5}$ (Li et al. 2019). Yet, it is uncertain how meteorological conditions influence th~~eis~~ increasing trend in surface O_3. Yang et al. (2019) quantified the meteorological impact on O_3 variation over the Pearl River Delta region using the meteorological adjustment. Using ~~Similarly to~~ the methodology similar to that in~~in~~ Yang et al. (2019), we investigate ~~the~~ meteorological influences on the increase in ozone ~~increase~~ over the YRD in the warm seasons during 2014–2018. Fig. 3a shows the ambient O_3 variation from 2014 to 2018: i.e. O_3 concentration increases from~~orm~~ 2014, reaches the maximum in 2017, and maintains at a relatively high level in 2018. After the meteorological adjustment, the variable~~increasing~~ magnitude is lower than the original one, implying that if the meteorological conditions remained unchanged over the 5 years, the variation~~ariableincreasing~~ in ~~magnitude of~~ ambient O_3 concentration would be lower. The meteorological impact can be examined from the difference between the black solid and dashed lines in Fig. 3a. ~~it is shown that~~ –T~~We focus on periods from the middle of 2014 to the middle of 2018 when t~~the difference is negative~~ly~~ from ~~the middle of~~ 2014 to the middle of 2016 and positive~~ly large~~ from middle of 2016 to ~~to the meddle of~~ 2018. In 2017, the meteorological conditions increase ~~the~~ O_3 concentration by about 1.16~~20~~ ppb. However, in 2015, the meteorological conditions become unfavorable to the O_3 accumulation, leading to an O_3 reduction of 1.39~~10~~ ppb. The meteorological conditions make a difference in ~~changed the~~ O_3 concentration by 3.03~~2.81~~ ppb at most between the most favorable year (2017) and the most unfavorable year (2015), which roughly corresponds to 8.70~~9.62~~% $(\frac{max(MEO\ imapct)-min(MEO\ impact)}{O3(5\ year\ average)})$ of the annual O_3 concentration.

In addition, we select the most influential meteorological factors to discuss their impacts on O_3 variation, including T2, RH, ~~sunshine duration~~SR, LCC and WS ~~and wind speed~~. As shown in Fig. 3b, RH is the most crucial factor and its variation is similar to the variation in the total meteorological impact. In addition, SR and LCC also play important roles and have ~~close~~large impacts ~~impacting~~ on O_3 variation. ~~It indicated that~~ –RH can i~~i~~mpact ~~s on~~ O_3 concentration in~~through~~ two ways. One is gas phase H_2O reacting with O_3 $(O_3 + H_2O(gas) + hv \to O_2 + 2OH)$. The other is its influencing on clouds and thereby shielding SR. The East Asian summer monsoon plays a key role in affecting the local RH, and meanwhile it might bring a certain amount of O_3 from

the areas south of the YRD ~~area~~. However, O_3 concentration is high negatively related to RH, which implies that the local chemical reaction might contribute to the O_3 accumulation more than the regional transport. The impacts of T2 and WS~~contributions of other two factors~~ are inconsistent with the overall ~~sum~~ meteorological impacts~~contribution.~~ ~~Han et al. (2020) also found that RH is the most influential factor in the central and south parts of eastern China. The East Asian summer monsoon plays a key role in affecting the local RH, and meanwhile it might bring a certain amount of O_3 from the south area. However, O_3 concentration is highly negatively related to RH, which implies that the local chemical reaction might contribute more to the O_3 accumulation than the regional transport. The contributions of the other three factors are relatively insignificant.~~

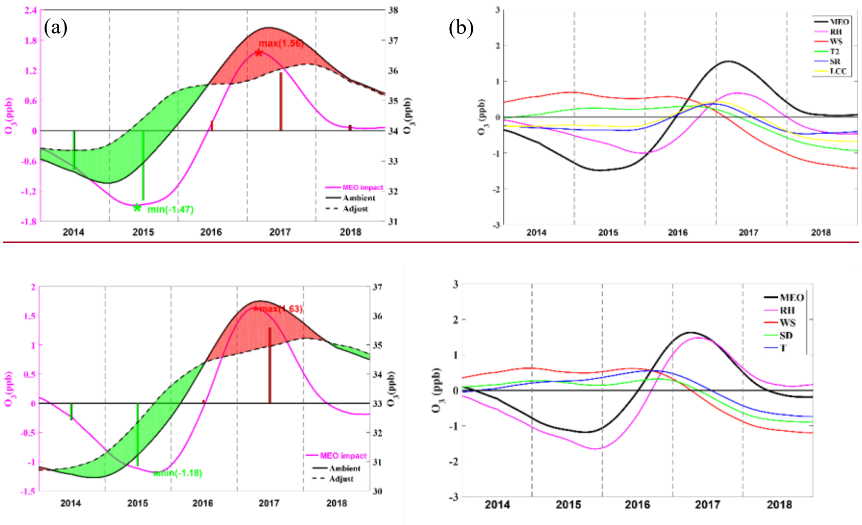

Fig. 3. (a) 5-year trends of ambient O_3 (solid black line), meteorological adjusted O_3 (dashed black line), and the meteorological impact (pink line) over the YRD during 2014–2018. Periods with positive and negative meteorological impacts are shaded in~~with~~ red and green, respectively; red and green bars represent the ~~the~~ O_3 increases~~ing~~ and decreases attributable to~~ing~~ ~~caused by~~ meteorological influences~~conditions~~ in each year. (b) 5-year variations in the meteorological impact of different meteorological factors (MEO~~R~~), including relative humidity (RH), ~~sunshine duration~~solar radiation (SR), air temperature (T2), ~~and~~ wind speed (WS~~P~~) and low cloud cover (LCC).

3.3. Dynamic processes of O_3 variation driven by synoptic circulations

As discussed in section 3.2, the local meteorological factors have a large great impact on the O_3 variation. However, to some extent, the variation in local meteorological factors is largely affected by the synoptic-scale weather circulations (Leibensperger et al. 2008; Fiore et al. 2003; Wang et al. 2016). For example, in summer the YRD is under a hot-wet environment controlled by the WPSH. While in winter it is under a cold-dry environment affected by the northwesterly flow caused by the Siberian High. The different weather systems under their corresponding SWPs have their unique meteorological characteristics. Moreover, even under one SWP, the location and intensity changes in a specific weather system can cause the changes in local meteorological factors correspondingly (Gao et al. 2020).

3.3.1. The main synoptic weather patterns in the warm season over the YRD

Applying the PTT classification method, nine SWPs are identified for the warm seasons in the YRD. Due to the relatively large variance, the first dominant five types SWPs are selected, and the other four SWPtypes are grouped as 'other types'. – As shown in Table 1, SWP1, SWP2 and SWP4 are dominant, accounting for 40.66%, 22.84% and 13.99% of the occurreeance frequencys, respectively. In contrast, SWP3, SWP5 and other types occur in low frequencies, being are relatively lower, and their occurrence frequencies are 7.65%, 6.99% and 6.01%, respectively. Specifically, SWP1 is under control ofaffected by the southweeasterly flow introduced by the WPSH. SWP2 is influenced by the northwesterly flow introduced by a persistent continental high pressure. SWP4 is influenced by the southeasterly flow introduced by the WPSH and a cyclone. SWP3 and SWP5 are affected by a cyclone and an anticyclone. For SWP1 and SWP4 are , it is with high temperature and humidity inducedaffected by the southerly flow. While under But for SWP5, the YRD is with high temperature and low RH because of the weak northerly flows are weakened and could not carrywhich brings insufficient water vapor, the YRD is with high temperature and low RH. SWP2 is with relatively lower temperature. SWP3 is under the control of a cyclone and the strong upward motion, it is with weak SR and low er T2. SIn order to avoid overabundance similar figures with Figs 4–8, Specific figures of atmospheric circulation at 850 hPa under the main five SWPs arewould

~~be~~ provided in the supplementary.

3.3.2. Impacts of SWP change on O_3 concentration variation

We explore the impacts of SWP change on O_3 variation through an analysis combined with ~~combining~~ ~~the~~ EOF1~~ mode~~. As illustrated in section 3.1.2, the EOF1 mode is the dominant mode, and it implies the increase of O_3 in the entire YRD~~whole area~~ is the main trend. The ~~Regarding~~ EOF1 time series is closely correlated to ~~, it has a high correlation coefficient with~~the ~~-~~regional mean O_3 concentration (R = ~~-~~0.98~~3~~). In this study, we primarily~~mainly~~ focus on why O_3 concentration increases in the entire YRD region, rather than on why the increases in O_3 differ spatially inside the YRD. Therefore, we use the EOF1 time series as a proxy to present the regional O_3 concentration. In Table 1, the positive phase (Pos) represents that the EOF1 time series is more than 0 and it is~~ not~~ beneficial to the production and accumulation of O_3. On the contrary, the negative phase (Neg) corresponds ~~means the~~ low~~higher~~ O_3 concentrations. We extract the information by comparing Pos~~Neg~~ with Neg~~Pos~~ to find the changes in~~of~~ each SWP pattern. Yin et al. (2019) explored dominant patterns of summer O_3 pollution and associated atmospheric circulation changes in eastern China. Differently from their study, we ~~have~~ analyzed the daily variation in SWPs, and thus~~can~~ identified ~~obtain~~ the change in atmospheric circulations in a higher temporal resolution~~more precisely~~.

In the five main SWPs, the EOF1 time series show an ~~decrease~~ increase trend during their occurrence days in the warm seasons. It means that the five main SWPs~~patterns~~ tend to bring~~cause~~ high ambient O_3 concentration through ~~the~~ changes in the SWPs, which ~~. In addition, the SWP change~~ include SWP changes ins both~~-~~ frequency and intensity~~ changes~~. We find that the ~~-~~change in SWP intensity~~frequency change in SWPs has less~~ impacts more significantly~~ on~~ the inter-annual variation in O_3 levels than the change in SWP frequency~~intensity change in SWPs~~, ~~-which is~~ consistent with the results of Hegarty et al. (2007) and Liu et al. (2019). This~~se contribution of intensity change and frequency change~~ will be further discussed in section 3.4. In the following, we will concretely discuss the variation characteristics of the five SWPs ~~-~~and their impacts onto the

带格式的: 非突出显示

increase of O_3 in the YRD. Especially, we will show atmospheric circulations at 850 hPa and 500 hPa, meteorological factors includ~~es~~ing SR, T2, LCC, TCLW, RH, meridional wind at 850hPa (V850) and W (vertical velocity) under positive and negative phase of all SWPs, and correlation coefficients of RH, SR and T2 with EOF1 time series under all SWPs ~~are shown~~.

As shown in ~~the~~ previous study, SR, T2 and RH are dominated meteorological factors and can ~~have extremely~~ directly impacts ~~on~~ O_3 photochemical formation and loss (Xie et al. 2017; Gao et al. 2020). To~~In order to the~~ explore the importance and difference of their impact~~effects~~ on O_3 concentrations under different~~each~~ SWPs, we calculate the correlation coefficients between the EOF1 time series and these meteorological factors~~em~~ under each SWP. As shown in table 2 and 3, when the absolute values of the calculated correlation coefficients under a SWP are~~are~~ greater than 0.4, the corresponding meteorological factors~~s~~ present significant changes between Pos~~s phase~~ and Neg phases. Therefore,~~Consequently,~~ we regard them~~conceive of them~~ as the crucial meteorological factors that impact~~impacting on~~ O_3 variation under that~~e~~ SWP. In the end, we find that significant~~ly~~ decreases in~~ing~~ RH and increases in~~strengthening~~ SR are the crucial meteorological factors under SWP1, SWP4 and SWP5. For SWP2, significant decreases in~~ly decreasing~~ RH, increases in~~strengthening~~ SR and ~~increasing~~ T are the crucial meteorological factors. For SWP3, significant~~ly~~ decreases in~~ing~~ RH is the crucial meteorological factor. Hereinafter, we ~~it would be~~ discussed variations in ~~how to lead to~~ crucial meteorological factors ~~variation~~ induced by change in atmospheric circulations.

TABLE 2. Correlation coefficient of RH, SR and T2 with EOF1 time series under each SWP.

Variables	SWP1	SWP2	SWP3	SWP4	SWP5
RH	-0.59	-0.52	-0.50	-0.64	-0.59
SR	0.58	0.56	0.33	0.46	0.48
T2	0.19	0.41	0.26	0.15	0.30

Fig. 4 shows the atmospheric circulations at 850 hPa and 500 hPa, and ~~the box plot of normalizing~~ Table 3 shows meteorological factors includ~~inges~~ SR, T2, TCC, TCLW, RH, ~~meridional wind at 850hPa (~~V850~~)~~ and W ~~(vertical velocity)~~ ~~in table 3~~ for SWP1_Pos and SWP1_Neg. As shown in Figs. 4a and 4b, the YRD is located at the northwest of the WPSH, mainly affected by the southwesterly winds. Ceompared with V850 of 4.27 m/s under SWP1_neg, weakening V850 of

2.89 m/s under SWP1_pos bring a less amount of water vapor to YRD region, therefore, RH shows a decrease trend and significantly decreases by 15.24%.Compared with the SWP1_Pos, the range of WPSH is wider in the northwest area under SWP1_Neg, leading to the strengthened southerly wind in the northwest, which results in higher temperature in this area. Due to the weakening of V850, the water vapor transport acts in response from the south. RH shows a decrease trend. At 500 hPa, a shallow trough located at approximate 113°E is replaced by a slowly moving weak ridgestraight westerly flow, and the downward motion would strengthen and last longer behind the shallow trough. The sink motion is favorable for the O_3 accumulation and O_3 photochemical reaction at the near surface. Besides, the significantly decreases ining water vaporRH under the downward motion condition hindermake the cloud cover hard to formation. LCC and TCLW decreaseed by 0.30 and 0.04, respectively.. SoFurthermore, SR significantly strincreases byonger 730.04 W/m^2solar radiation hits the ground due to the less shelter from of the clouds and less reflection above the cloud. Eventually, , furthersignificantly decreases ining RH and increases in strengthening SR –leading to higher air temperature and stronger O_3 photochemical reaction.

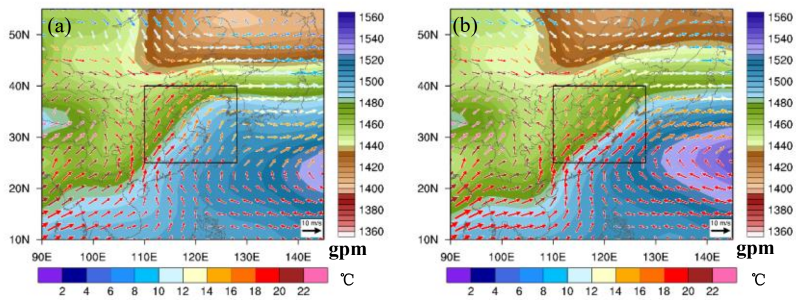

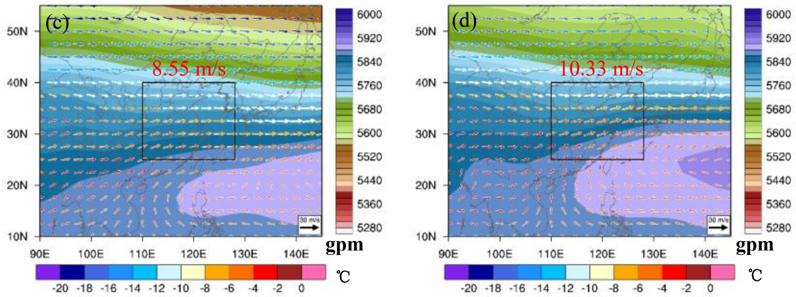

Fig. 4. The geopotential height (shaded) and 850-hPa wind with temperature (color vector) under (a) SWP1_Pos and (b) SWP1_Neg. The geopotential height (shaded) and 500-hPa wind with temperature (color vector) under (c) SWP1_Pos and (d) SWP1_Neg. The red values represent the regionally averaged wind speed at 500 hPa in the zone around black lines.~~(e) The regional average meteorological factors under SWP1_Pos and SWP1_Neg, including SR, TCC, 2-m air temperature, RH, meridional wind at 850 hPa (V850) and W (vertical velocity).~~ The boxed area in Figs. 4a-4d encloses the YRD.

带格式的: 非突出显示

Fig. 5 shows the atmospheric circulations ~~structures~~ at 850 hPa and 500 hPa, and Table 3 shows meteorological factors including~~es~~ SR, T, TCC, TCLW, RH, V850 and W ~~in table 3the box plot of normalizing factors includes SR, T, TCC, RH, V850 and W~~ for SWP2_Pos and SWP2_Neg. As shown in Figs. 5a and 5b, the YRD is affected by a continental high and the Aleutian low, characterized by northwesterly flow and a bit southwesterly flow. Compared with the SWP2_Pos, ~~the northwesterly flow introduced by~~ the continental high in SWP2_Neg is weakening~~er~~. Therefore,~~So~~ the YRD region is~~would be~~ influenced by ~~the~~ warm flows and T2 ~~would~~ significantly increases by 4.91 ℃. The correlation between the EOF1 time series and ~~2-m air temperature~~T2 under SWP2 (R_{SWP2} = −0.41) is closer than the correlation in the whole period (R_{all} = −0.24). This implies that the weakening of the continental high plays an important role in enhancing O_3 there. Meanwhile~~At the same time~~, as the Aleutian low moves southward slightly, the southwesterly flow can hardly bring water vapor to the YRD, which leads to ~~RH~~ significant~~ly~~ decreases in RH by 14.79% ~~in this area~~. ~~The correlation between the EOF1 time series and 2-m air temperature under~~

SWP2 (R_{P2} = −0.41) is closer than the correlation in the whole period (R_{all} = −0.24). This implies that the weakening of the continent high plays an important role in enhancing O_3 there. At 500 hPa, a trough located at approximate 120°E–125°E is strengthened associated with Aleutian low shifting southward, leading to the stronger downward motion in the northwestern YRD behind the strengthening trough. Just like SWP1, stronger downward motion and significantlyly decreasinglower RH enhanceeause strong SR significantly increasing by 790.06 W/m^2 and high air temperature. All these changesSsignificantly decreasing RH, strengthening SR and increasing T2 are beneficial to the O_3 formation and accumulation.

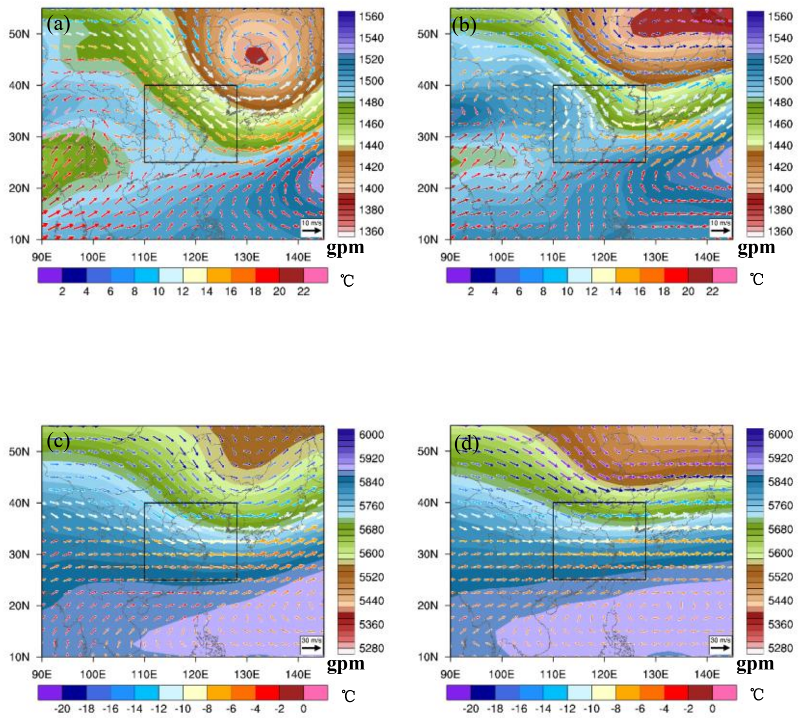

Fig. 5. The geopotential height (shaded) and 850-hPa wind with temperature (color vector) under (a) SWP2_Pos and (b) SWP2_Neg. The geopotential height (shaded) and 500-hPa wind with temperature (color vector) under (c) SWP2_Pos and (d) SWP2_Neg. The red values

represent regional average wind speed at 500 hPa in the zone around black lines. (e) The regional average meteorological factors under SWP2_Pos and SWP2_Neg, including SR, TCC, 2-m air temperature, RH, meridional wind at 850 hPa (V850) and W. The boxed area in Figs. 5a-5d encloses the YRD.

Fig. 6 shows the atmospheric circulations at 850 hPa and 500 hPa, and Table 3 showsand meteorological factors including includes SR, T, TCC, TCLW, RH, V850 and W in table 3 the box plot of normalizing factors includes SR, T, CC, RH, V850 and W for SWP3_Pos and SWP3_Neg. As shown in Figs. 6a and 6b, the YRD is controlled by an extratropical cyclone. Compared with the SWP3_Pos, the low pressure in SWP3_Neg is lower and its location is slightly further eastward SWP3_Neg. Under this circumstance, the southerly flow at the bottom of the low pressure could hardly bring the water vapor to the YRD and thus ,. RH would significantly decreases by 11.73%. At 500 hPa, –the upward motion would be weakening due to the eastern movement of cyclone and western area controlled by back of a strengthening trough located at about 120°E. However, but LCC still is at a high level under upward motion condition. Furthermore, high LCC and its less variation lead to low SR. Therefore, the It is proving that relative low SR correlation coefficient of -0.33 between SR and with EOF1 time series is relatively low for this SWP3 (r=-0.33). Lastly, only significantly decreasing RH would be crucial factor forand result in high O_3 concentration the downward motion would be strengthened due to the strengthened trough. The intense downward motion and low RH result in less CC and strong SR, as well as high T, which are instrumental in high O3 concentration.

3.4. Indicators for reconstructing inter-annual O_3 variation affected by synoptic-scale atmospheric circulation

Due to the similar variations in regional mean O_3 concentration and EOF1 time series, we have reconstructed the inter-annual EOF1 time series to replace the regional mean O_3 concentration by ~~taking into~~ accounting either frequency-variation-only or both frequency and intensity variations in SWPs, which are EOF1 time series (Fre) and EOF1 time series (Fre + Int), respectively. The observed and reconstructed inter-annual EOF1 time series in 2014–2018 over the entire YRD~~in the whole~~ region are shown in Fig. 9. Obviously, the frequency changes in SWPs almost have no impact on the O_3 variability in the entire YRD. ~~Regarding~~ However, considering~~the~~ intensity change, the fitting curve would be closer to the EOF1 time series. To~~In order to~~ obtain the accurate frequency and intensity change contributions, quantitative evaluation is carried out, we define the contribution index as the difference between the maximum ~~value~~ and the minimum ~~one~~ of a certain reconstructed time series divided by the difference between the maximum~~value~~ and the minimum ~~value~~ of ~~inter-~~annual EOF1 time series: Contribution Index = (The reconstructed maximum~~value~~ – the reconstructed minimum~~value~~)/(the original maximum~~value~~ – the original minimum~~value~~). Through the above equation, we derive~~get~~ the relative contribution (contribution index) of the frequency change and the intensive change. Compared with the contribution index of 10.86% for SWPs frequency change, the value of 48.89% for SWPs intensity change accounts for a larger proportion. Therefore, the intensity change in SWP is more important to the inter-annual O_3 variation than the frequency change.

~~Obviously, the frequency changes in SWPs almost have no impact on the O_3 variability in the entire YRD. Regarding the intensity change, the fitting curve would be closer to the EOF1 time series.~~ During the reconstructed process, we drastically found that SWPIIs (SWP intensity indexes) definition play an important role to reconstructing curve. In ~~As~~ previous studiesy, Hegarty et al. (2007) and Liu et al. (2019) reconstructed the inter-annual O_3 level in the northeastern United States and the northern China using the same method as ours. ~~Moreover,~~ They defined the intensity change

带格式的: 字体颜色: 文字 1

带格式的: 字体颜色: 文字 1

带格式的: 字体颜色: 文字 1

带格式的: 字体颜色: 蓝色

in SWPs using the domain-averaged sea level pressure and the pressure of the lowest-pressure system. However, ~~As illustrated by Hegarty et al. (2007), but~~ the correlation under Hegarty's Pattern V is poor, which has negative effect on their reconstructed curve. ~~It indicates we should select the SWPIIs under each pattern according to their unique characteristics on high O_3 concentration.~~ Therefore,~~So~~ w~~W~~e select six SWPIIs and judge their rationality through their correlation coefficients with EOF1 time series under each SWP: the maximum geopotential height~~pressure~~ in zone 1 (25°N–40°N, 110°E–130°E) and zone 2 (20°N–50°N, 90°E–140°E), the minimum geopotential height~~pressure~~ in zone 1 (25°N–40°N, 110°E–130°E) and zone 2 (20°N–50°N, 90°E–140°E), and the average geopotential height~~pressure~~ in zone 1 (25°N–40°N, 110°E–130°E) and zone 3 (10°N –40°N, 110°E–130°E). As shown in Table 2, for SWP3 and SWP5, the SWPII for the maximum geopotential height~~pressure~~ in zone 1 has a relative high correlation ~~between SWP3 and SWP5~~. For~~,~~ SWP1 and SWP4, ~~and~~ the SWPII for the maximum geopotential height~~pressure~~ in zone 2 has a relative high correlation ~~between SWP1 and SWP4~~. we found that ~~The annual EOF1 time series anomalies~~ the maximum geopotential height show a relatively close ~~good~~ correlation with the annual EOF1 time series ~~the maximum pressure~~. It is~~. It is~~ because the maximum geopotential height~~pressure~~ reflects the wind speed affecting~~g the~~ water vapor transport under this pattern. Compared with SWP3 and SWP5, the ~~synoptic~~ weather systems are~~is~~ larger than the classification region for SWP1 and SWP4. So it shows~~So it can represent~~ better correlation coefficients~~the SWPII more precisely~~ in the~~a~~ large zone 2 than in zone 1 under SWP1 and SWP4~~region~~. ~~Under~~ For SWP2, when O_3 concentration tends to be at a high level, a cold continental high behind the YRD ~~would~~ tends to weaken. Therefore, we select the average geopotential height~~height~~ in zone 3 to represent the SWPII ~~under SWP2~~. ~~From~~ Table 4~~2~~ shows that~~, we can know~~ the ~~it has better~~ reconstructed curve becomes good when we selected~~ed~~ different SWPIIs according to the characteristics of high O_3 level under each ~~pattern~~SWP. ~~Above all, the intensity change in SWP is more important to the inter-annual O_3 variation than the frequency change.~~

4. Conclusions and discussions

In this study, we discussed ~~the~~ meteorological influences on the O_3 variation in the warm seasons during 2014–2018 in the YRD, China. Specifically, we analyzed the O_3 spatio-temporal distribution characteristics, quantified the contribution of meteorological conditions to the O_3 variations, explored how ~~the~~ changes in SWPs and corresponding meteorological factors lead to O_3 increase in the YRD over 2014–2018, and assessed ~~quantitatively analyzed~~ the contributions ~~impact~~ of SWP frequency and intensity to~~on~~ the inter-annual O_3 variation in the region. The main conclusions are as follows.

The annual mean~~regional averaged~~ O_3 concentrations during the warm seasons averaged over~~from 2014 to 2018 in~~ the YRD are 32.49, 33.03, 35.14, 37.44 and 35.98 ppb, respectively, for each year from 2014 to 2018, with a significantly increasing rate of 1.81 ppb year^{-1} (5.21% year^{-1}). Meanwhile~~At the same time~~, the total number of days on which O_3 concentration exceed~~ings~~ the national standard also increases with year in a similar pattern. Through the EOF analysis of O_3 in space and time, three dominant modes were identified. The first mode is the most dominant mode, accounting for 65.7% of the O_3 variation, suggesting~~implying~~ that increase tendencies in ~~the~~ O_3 ~~increasing~~ prevail over ~~in~~ the entire YRD ~~is the main tendency~~. ~~A high correlation coefficient between the EOF1 time series and RH (R_{rh} = 0.59) indicates that RH is the most influential factor leading to the O_3 increase.~~

We quantified the influence of meteorology on the inter-annual variation and trend of O_3 over the YRD from 2014–2018, and found that the influence could lead to a regional O_3 increase by

带格式的: 下标

3.03~~2.81~~ ppb at most. Especially~~, compared to SR and LCC of relatively large impacting on O_3 variation,~~ RH– plays the most~~s the most~~ important role in modulating the inter-annual O3 variation, followed by SR and LCC. ~~It indicated that~~ RH impacts on O_3 concentration through two ways. One is gas phase H_2O reacting with O_3 ($O_3 + H_2O(gas) + h\nu \rightarrow O_2 + 2OH$). The other is its influencing on clouds and thereby shielding SR. To~~Moreover, in order to~~ explore connections between the O_3 variation and synoptic circulations, we further identified nine types of SWPs ~~were~~ objectively ~~identified~~ based on the PTT method, and selected five main types ~~were selected~~ to explore their impact on O_3 variation.~~correlate with the EOF1 time series.~~ The typical weather systems of the five SWPs include the WPSH under SWP1, a continental high under SWP2, an extratropical cyclone under SWP3, a southern low pressure and a WPSH under SWP4 and the north China anticyclone under SWP5. Combining EOF1 time series variation under each SWP, w~~W~~e found that the variation in all SWPs over 2014–2018 are favorable to O_3 increase during~~in~~ that period. ~~The variation in SWP intensity include the WPSH weakening and northward extending under SWP1, a continent high weakening under SWP2,~~ However, the crucial changes in meteorological factors attributable to the increases in~~causing the increasing of~~ O_3 concentrations are different under each SWP. For SWPs 1, ~~SWP~~4 and ~~SWP~~5, the crucial changes in meteorological factors include significant decreases in~~factors are significantly decreasing~~ RH and increases in~~strengthening~~ SR, which are predominantly attributable to~~caused by~~ the WPSH weakening and northward extending under SWP1, the southern low pressure weakening and the WPSH weakening under SWP4, and the north China anticyclone weakening under SWP5. These changes in weather systems prevent the water vapor from being transported to the YRD and result in RH significantly decreased by 15.24, 12.26 and 17.34%, respectively. Moreover, the significant~~ly~~ decreases in~~ing~~ RH and increases in~~the strengthening~~ downward motion (behind the strengthening trough and in front of the strengthening ridge) lead to less LCC, and thereby SR significantly increases by 730.04, 538.53 and 628.26 W/m^2, respectively. Under~~For~~ SWP2, the crucial changes in meteorological factors are significant~~ly~~ decrease in~~creasing~~ RH by14.79%, and increases in~~, strengthening~~ SR by 790.06 W/m^2 and ~~increasing~~ T2 by 4.91 ℃. ~~RH significantly decreases by 14.79%, SR significantly strengthenincreasess by 790.06 W/m^2 and T2 significantly increases by 4.91 ℃.~~ These changes are mainly ~~chiefly~~ induced~~produced~~ by a continent high weakening, which has a similar

influential mechanism between RH, LCC and SR with SWPs 1, 4 and 5.~~,~~ I~~i~~n addition, significantly increases in~~ing~~ T2 would be due to weakening cold flow introduced by a weakening continent high. Under~~For~~ SWP3, the ~~they are~~ significant~~ly~~ decreases in~~creasing~~ RH ~~. Under SWP3, RH significantly decreasesd~~ by 11.73% is mainly induced by an intensified extratropical cyclone that~~strengthening~~ blocks the southerly flow carrying water vapor into the YRD. These change are critical to O_3 formation under each SWP.

As the overall change in SWP intensity and that in SWP frequency contribute to~~Compared~~ 498.89% and ~~of contribution index of SWP intensity change to~~ 110.86% to the changes in ~~of~~ ozone, we conclude that the change in SWP intensity~~contribution index of SWP frequency change, an extratropical cyclone strengthening under SWP3, the southern low pressure weakening and the WPSH weakening under SWP4, and the north China anticyclone weakening under SWP5. All these changes prevent the water vapor from being transported to the YRD and increase air temperature in YRD. In addition, the downward motions strengthen in the YRD, which is behind the trough and in front of the ridge due to the strengthening of the ridge and trough, leading to less cloud cover and stronger SR. All of these are favorable to O_3 formation and accumulation.~~

it is~~We found that the change in SWPs intensity~~ is more important to the O_3 increase over 2014–2018 than that in SWP~~s~~ frequency. We further reconstructed the EOF1 time series by considering different SWPIIs due to the unique characteristics of each SWP. The results are better than those in Hegarty et al. (2007) and Liu et al. (2019) who used the same SWPIIs in all SWPs.

T~~In summary, t~~his study quantified the inter-annual variation and increasing rate of O_3 in the YRD, China, and explored the connection between SWP variations and the O_3 increase. It provides an enhanced understanding of response of O_3 variation to changes in SWPs from year to year and thus this understanding may be insightful to planning strategies for O_3 pollution control.
