**Correspondence:** Johannes G.M. Barten (sjoerd.barten@wur.nl)

**Abstract.** Dry deposition is an important removal mechanism for tropospheric ozone (O<sub>3</sub>). Currently, O<sub>3</sub> deposition to oceans in atmospheric chemistry and transport models (ACTMs) is generally represented using constant surface uptake resistances. This is despite the fact that considering the role of solubility, waterside turbulence and O<sub>3</sub> reacting with ocean water reactants such as iodide ~~and dissolved organic matter~~ results in substantial spatiotemporal variability in O<sub>3</sub> deposition and concentrations in marine boundary layers. We hypothesize that O<sub>3</sub> deposition to the ~~cold~~-Arctic ocean, ~~with having a~~ relatively low reactivity, is ~~also~~ overestimated in current models with consequences for ~~background tropospheric~~ concentrations, lifetime of O<sub>3</sub> and long-range transport of O<sub>3</sub>. In this study, we investigate the ~~role-impact~~ of the representation of oceanic O<sub>3</sub> deposition to the simulated magnitude and spatiotemporal variability in Arctic surface O<sub>3</sub>. ~~This study also serves as a preparatory study to understand the year-round Arctic O<sub>3</sub> concentration and deposition flux measurements as part of the MOSAiC field campaign. Furthermore, it is also important to enhance our understanding and quantification of Arctic ocean-atmosphere exchange of O<sub>3</sub> and other climate-active trace gases given the anticipated opening of the Arctic ocean.~~

We have ~~coupled-integrated~~ the Coupled Ocean-Atmosphere Response Experiment Gas transfer algorithm (COAREG) ~~to~~ into the mesoscale meteorology and atmospheric chemistry model Polar-WRF-Chem (WRF) ~~and introduced-which introduces~~ a dependence of O<sub>3</sub> deposition on ~~ocean waterside turbulent mixing conditions and biogeochemical composition~~ physical and biogeochemical drivers of oceanic O<sub>3</sub> deposition. We have also reduced the O<sub>3</sub> deposition to sea ice and snow. Here, we evaluate the performance of WRF and the CAMS reanalysis data against hourly-averaged surface O<sub>3</sub> observations at 25 sites (latitudes > 60 °N) including the ~~ASCOS~~ Arctic Summer Cloud Ocean Study (ASCOS) campaign observations. This is the first time such a coupled modelling system has been evaluated against hourly observations at Pan-Arctic sites to study the sensitivity of the deposition scheme to the magnitude and short-term temporal variability in Arctic surface O<sub>3</sub>. We also analyze the impact of nudging WRF to the synoptic conditions from the ECMWF ERA5 reanalysis data on simulated Arctic meteorology and comparison of observed and simulated O<sub>3</sub> concentrations.

We show that the more mechanistic representation of O<sub>3</sub> deposition over oceans and reduced snow/ice deposition improves simulated Arctic O<sub>3</sub> mixing ratios both in terms of magnitude but also regarding observed temporal variability. Using the newly implemented approach, O<sub>3</sub> deposition velocities have been simulated in the order of 0.01 cm s<sup>-1</sup> compared to ~0.05 cm s<sup>-1</sup> in the constant surface uptake resistance approach. The simulated monthly-mean spatial variability in the mechanistic approach (0.01 to 0.018 cm s<sup>-1</sup>) expresses the sensitivity to chemical enhancement with dissolved iodide whereas the temporal variability

(up to  $\pm 20\%$  around the mean) expresses mainly differences in waterside turbulent transport. The bias for all observational sites above  $70^\circ\text{N}$  reduced from  $-7.7$  ppb to  $0.3$  ppb with nudging and the revision to ocean and snow/ice deposition. Our study confirms that  $\text{O}_3$  deposition to high-latitude oceans and snow/ice is ~~overestimated in current models~~ generally overestimated in ACTMs. We recommend that a mechanistic representation of oceanic  $\text{O}_3$  deposition ~~is~~ should be used in ACTMs to improve the representation of Arctic surface  $\text{O}_3$  concentrations in terms of magnitude and short-term temporal variability. ~~The revised ocean-atmosphere exchange representation can be further refined using the MOSAiC flux measurements as well as complementary observations such as sea ice and ocean water iodide concentrations.~~

## 1 Introduction

35 Tropospheric Ozone ( $\text{O}_3$ ) is the third most important greenhouse gas and a secondary air pollutant negatively affecting human health (Nuvolone et al., 2018) ~~and~~ plant growth (Ainsworth et al., 2012) and artificial materials such as rubber (Lee et al., 1996) due to its oxidative character.  $\text{O}_3$  shows a large spatiotemporal variability due to its relatively short lifetime (3-4 weeks) in the free troposphere compared to other greenhouse gases. Its main sources are chemical production and entrainment from the stratosphere. Its main sinks are chemical destruction and deposition to the Earth's surface (Young et al., 2018; Tarasick et al., 2019).  
40 . Understanding the Arctic  $\text{O}_3$  budget is of particular interest because its remote location implies that anthropogenic sources and sinks are generally absent. This makes these ~~background-Arctic~~  $\text{O}_3$  observations ~~an excellent indicator for global trends (Helmig et al., 2007b; Gaudel et al., 2020)~~ excellent indicators for global trend analysis (Helmig et al., 2007b; Gaudel et al., 2020; Cooper et al., 2014). In the Arctic, routine tropospheric  $\text{O}_3$  observations indicate an increasing trend up to the early 2000s which is leveling off (Oltmans et al., 2013; Cooper et al., 2014) ~~or decreasing at individual sites (Cooper et al., 2020)~~ in the last decade (Oltmans et al., 2013; Cooper et al., 2014).  
45 . This upward trend can be attributed to increased emissions of precursors in the mid-latitudes (~~Cooper et al., 2014~~) ~~but also (Cooper et al., 2014; Lin et al., 2017), but also changes in  $\text{O}_3$  deposition to vegetation as a result of droughts and heatwaves (Lin et al., 2020) and~~ stratosphere-to-troposphere transport may have played a role (Pausata et al., 2012). Local emissions of precursors are expected to become an important source of Arctic  $\text{O}_3$  concentrations due to the warming Arctic climate and increasing local economic activity (Marelle et al., 2016; Law et al., 2017). This ~~stresses the need to better understand~~ underlines the need for understanding the sources and sinks of Arctic tropospheric  $\text{O}_3$  and to accurately represent them in atmospheric chemistry and transport models (ACTMs).

On the global scale, dry deposition accounts for  $\sim 25\%$  of the total sink term (Lelieveld and Dentener, 2000) in ACTM simulations and is especially important for the  $\text{O}_3$  budget in the Atmospheric Boundary Layer (ABL) because it occurs at the Earth's surface (~~Hardaere et al., 2015~~) (Kavassalis and Murphy, 2017; Lin et al., 2019, 2020). Dry deposition in ~~such model assessments~~ ACTMs is often represented as a resistance in series approach (Wesely, 1989). In this approach the total resistance  $r_t$  is the sum of three serial resistances: the aerodynamic resistance ( $r_a$ ) representing turbulent transport to the surface, the quasi-laminar sub layer resistance ( $r_b$ ) representing diffusion close to the surface and the surface resistance ( $r_s$ ) expressing the efficiency of removal by the surface. The dry deposition velocity ( $V_d$ ) is then evaluated as the reciprocal of  $r_t$ . The  $r_a$  term is independent of the chemical species and mainly depends on the stability of the atmosphere and friction velocity

60  $(u_*)$  (Padro, 1996; Toyota et al., 2016). The  $r_b$  term also scales with  $u_*$  and varies with the diffusivity of the chemical species (Wesely and Hicks, 2000). For very soluble species or reactive species such as nitric acid uptake by the ocean water is very fast, expressed by a (i.e.  $r_s$  of  $\sim 0 \text{ s m}^{-1}$ ), implying that the other resistances determine  $r_t$  and thus  $V_d$ . Less soluble gases, like  $\text{O}_3$ , have a high  $r_s$  that mainly, in comparison to the relatively small  $r_a + r_b$  term, that dominates the magnitude of the  $\text{O}_3$  dry deposition velocity ( $V_{d,\text{O}_3}$ ). Thus, accurately representing the surface uptake efficiency is of high importance of  $\text{O}_3$  is crucial.

65 Even though Observed  $\text{O}_3$  deposition to oceans (e.g. Chang et al., 2004; Clifford et al., 2008; Helmig et al., 2012) and coastal waters (e.g. Gallagher et al., 2001) is relatively slow compared to terrestrial surfaces, expressed by typically observed ocean  $V_{d,\text{O}_3}$  of ( $\sim 0.01\text{-}0.1 \text{ cm s}^{-1}$  (e.g. Helmig et al., 2012)), especially compared to observed maximum  $V_{d,\text{O}_3}$  for forests up to  $2 \text{ cm s}^{-1}$  (Fan et al., 1990). However, it plays a large role in the total  $\text{O}_3$  deposition budget due to the large surface area of water bodies (Ganzeveld et al., 2009)(Ganzeveld et al., 2009; Hardacre et al., 2015). Recent experimental and modelling studies

70 indicate the spatiotemporal variability in oceanic  $\text{O}_3$  uptake efficiency (Ganzeveld et al., 2009; Helmig et al., 2012; Luhar et al., 2018). However, most models-~~ACTMs~~ often still use a constant  $\text{O}_3$  surface uptake efficiency of  $2000 \text{ cm s}^{-1}$  to water bodies, proposed by Wesely (1989), resulting in a simulated ocean  $V_{d,\text{O}_3}$  of  $\sim 0.05 \text{ cm s}^{-1}$ . The observed  $V_{d,\text{O}_3}$  shows a larger variability including also a dependency on wind speed and Sea Surface Temperature (SST) (Helmig et al., 2012). The dependency on wind speed also expresses an enhancement of  $\text{O}_3$  deposition due to waterside turbulence (Fairall et al., 2007).

75 This turbulence driven enhancement is complemented by a strong chemical enhancement of oceanic  $\text{O}_3$  deposition associated with its chemical destruction through oxidation of ocean water reactants such as dissolved iodide and dissolved organic matter (DOM) (Chang et al., 2004). Mechanistic  $\text{O}_3$  deposition representations in models include the physical and biogeochemical processes related to the exchange and destruction of  $\text{O}_3$  in surface waters (Fairall et al., 2007, 2011; Ganzeveld et al., 2009; Luhar et al., 2017, 2018). Dissolved iodide is deemed to be the main reactant of  $\text{O}_3$  in surface waters (Chang et al., 2004)

80 and therefore often applied in these representations. Some studies only consider dissolved iodide as a reactant (Luhar et al., 2017; Pound et al., 2019) whereas Ganzeveld et al. (2009) also included DOM as one reactant contributing to the chemical enhancement of oceanic  $\text{O}_3$  deposition. However, the role of DOM in oceanic  $\text{O}_3$  deposition remains difficult to quantify and which appears to be mainly addressed by controlled laboratory measurements-experiments or  $\text{O}_3$  flux measurements at sites with elevated DOM water concentrations. Nevertheless, application of these more mechanistic ocean  $\text{O}_3$  deposition representations

85 illustrated the importance of a more explicit representation of  $\text{O}_3$  dry deposition in ACTMs, not only regarding the impact on marine ABL  $\text{O}_3$  concentrations and budget, but also to consider potentially important feedback mechanisms. For instance, the implementation of these mechanistic exchange methods in ACTMs indicates a  $\sim 50\%$  reduction of the global mean  $V_{d,\text{O}_3}$  which affects the tropospheric  $\text{O}_3$  burden (Pound et al., 2019). This mechanistic representation especially results in a simulated decrease in  $V_{d,\text{O}_3}$  to cold polar waters with relatively low reactivity. Simulated  $V_{d,\text{O}_3}$  can be as low as  $0.01 \text{ cm s}^{-1}$  compared to

90 the commonly applied  $V_{d,\text{O}_3}$  of  $0.05 \text{ cm s}^{-1}$  in the constant surface uptake resistance approach (Pound et al., 2019). Regarding feedback mechanisms, consideration of the mechanisms that ultimately determine the efficiency of uptake and destruction of  $\text{O}_3$  in ocean surface waters might also explain the release of halogen compounds into the ABL (Prados Roman et al., 2015). These halogen-compounds-halogens, in turn, are involved in  $\text{O}_3$  depletion in the ABL and therefore reduce further uptake and destruction of  $\text{O}_3$  in ocean surface waters implying existence of a negative feedback mechanism.

95 Up until now, earlier studies ~~have mostly focused on the effects on the global scale (Ganzeveld et al., 2009; Luhar et al., 2017)~~  
~~using on global scale oceanic O<sub>3</sub> deposition (Ganzeveld et al., 2009; Luhar et al., 2017)~~ mainly relied on the evaluation of  
monthly mean surface O<sub>3</sub> observations (Pound et al., 2019). ~~However, the hypothesized reduction in O<sub>3</sub> deposition~~ ~~The~~  
~~implementation of these mechanistic exchange methods in ACTMs, in particular the method proposed by Luhar et al. (2018)~~  
~~using a two-layer model representation (compared to a bulk layer version by Ganzeveld et al. (2009)), results in a ~50%~~  
100 ~~reduction of the global mean  $V_{d,O_3}$  which affects the tropospheric O<sub>3</sub> burden (Pound et al., 2019). The mechanistic representation~~  
~~in Pound et al. (2019) especially results in a simulated decrease in  $V_{d,O_3}$  to cold polar waters with relatively low reactivity.~~  
~~Simulated  $V_{d,O_3}$  can be as low as 0.01 cm s<sup>-1</sup> compared to the commonly applied  $V_{d,O_3}$  of 0.05 cm s<sup>-1</sup> in the constant surface~~  
~~uptake resistance approach (Pound et al., 2019). However, the hypothesized deposition reduction~~ to cold waters is ~~also~~ ex-  
pected to substantially affect Arctic ABL O<sub>3</sub> concentrations on shorter timescales and potentially improve operational Arctic  
105 O<sub>3</sub> forecasts, e.g. the air quality forecasts by the Copernicus Atmosphere Monitoring Service (CAMS) (Inness et al., 2019). ~~An~~  
~~improved representation of sub-monthly Arctic O<sub>3</sub> concentrations helps to constrain the background O<sub>3</sub> concentrations in terms~~  
~~of magnitude and variability whereas the~~  
~~The~~ evaluation of simulated oceanic O<sub>3</sub> deposition in the Arctic is hampered by a lack of O<sub>3</sub> ocean-atmosphere flux observa-  
tions. Hence, evaluation of simulated O<sub>3</sub> deposition relies on evaluation of surface O<sub>3</sub> concentrations ~~not only regarding the~~  
110 ~~simulated and observed magnitude but~~ in particular on the highly resolved temporal variability. We hypothesize that on the  
daily and diurnal timescales these concentrations ~~are~~ largely controlled by temporal variability in the main physical drivers  
of oceanic O<sub>3</sub> deposition, e.g. atmospheric and waterside turbulence. Chemical enhancement of, e.g., iodide to O<sub>3</sub> deposi-  
tion is anticipated to control more the long-term (weeks-months) baseline level of  $V_{d,O_3}$  associated with anticipated ~~more~~  
long-term (e.g. ~~seasonal~~) changes in ocean water biogeochemical conditions (Sherwen et al., 2019). This evaluation of Arctic  
115 ~~spatiotemporal~~ O<sub>3</sub> concentrations ~~in terms of magnitude and short- and long-term variability~~ aims to better understand sinks,  
processes, feedbacks and impacts of Arctic air pollution (Arnold et al., 2016) and the role of long-range transport (e.g. Thomas  
et al., 2013; Marelle et al., 2018) versus local sources (e.g. Marelle et al., 2016; Law et al., 2017; Schmale et al., 2018). Fur-  
thermore, the ~~anticipated-projected~~ opening of the Arctic ocean, as ~~one of the key features of Arctic~~ ~~a result of~~ climate change,  
urges to improve our understanding of Arctic ocean-atmosphere exchange. ~~In this study we only focus~~ ~~This study focuses~~ on  
120 the ocean-atmosphere exchange of O<sub>3</sub>, but follow-up studies are planned with a focus on ocean-atmosphere exchange and ABL  
concentrations of other trace gases such as dimethylsulfide (DMS), which enhances cloud formation and is involved in many  
feedback mechanisms (Mahmood et al., 2019).  
~~The main objective of this study is to address the role~~ ~~We aim to identify and quantify the impact~~ of a mechanistic representa-  
tion of O<sub>3</sub> deposition in explaining observed hourly Arctic surface O<sub>3</sub> concentrations, both in terms of magnitude and temporal  
125 variability. A ~~mesoscale~~ coupled meteorology-atmospheric chemistry model is ~~set up for an end-of-summer period in 2008 and~~  
evaluated against a large dataset of pan-Arctic O<sub>3</sub> observations at a high resolution (hourly) timescale ~~for the end-of-summer~~  
~~2008~~. Having a much higher spatial and temporal resolutions compared to other global modelling studies we aim to better  
capture the role of spatiotemporal variability in O<sub>3</sub> deposition in explaining observed surface O<sub>3</sub> concentrations ~~in particular~~  
~~particularly~~ regarding temporal variability. We also indicate the role of meteorology in simulating these O<sub>3</sub> concentrations by

130 nudging the simulated synoptic conditions towards an atmospheric reanalysis dataset. ~~This study also serves as a preparatory study to understand the year-round Arctic O<sub>3</sub> concentration and deposition flux measurements including the role of the local meteorology such as boundary layer mixing and entrainment as part of the Multidisciplinary drifting Observatory for the Study of Arctic Climate (MOSAIC) campaign (-, last access: 16 September 2020).~~ Section 2 describes the adjustments to the deposition scheme [in the mesoscale ACTM](#), further model setup and observational datasets. Section 3 presents the main results of the  
135 study which are further discussed in Sect. 4. This manuscript is finalized with the conclusions in Sect. 5.

## 2 Methods

### 2.1 Regional coupled meteorology-chemistry model

We use the Weather Research and Forecasting model (v4.1.1) coupled to chemistry (Chem) (Grell et al., 2005) and optimized for Polar regions (Hines and Bromwich, 2008). Polar-WRF-Chem (hereafter: WRF) is a non-hydrostatic mesoscale  
140 numerical weather prediction and atmospheric chemistry model used for operational and research purposes. Figure 1 shows the selected study area including the locations of surface O<sub>3</sub> observational sites ~~that will be used in this study - selected for this study (more information in Sect. 2.3).~~ WRF is set up with a polar projection centered at 90°N, 250×250 horizontal grid points (30×30 km resolution) and 44 vertical levels up to 100 hPa, with a finer vertical grid spacing in the ABL and lower troposphere. The simulation period is ~~08-08-2008 to 07-09-2008~~ [08-August-2008 to 07-September-2008](#) including three  
145 days of spin-up. This end-of-summer 2008 period is chosen ~~for two reasons:~~ 1) to limit the role of [active](#) halogen chemistry during springtime ([Pratt et al., 2013; Thompson et al., 2017](#)) ([Pratt et al., 2013; Thompson et al., 2017; Yang et al., 2020](#)) and 2) the additional availability of O<sub>3</sub> observations in the high Arctic over sea ice from the ASCOS campaign (Paatero et al., 2009). The ECMWF ERA5 meteorology (0.25°×0.25°) (Hersbach et al., 2020) and CAMS reanalysis chemistry (0.75°×0.75°) (Inness et al., 2019) products are used for the initial and boundary conditions. Boundary conditions, SSTs and sea ice fractions  
150 are updated every three hours to these reanalysis products to allow for the sea ice retreat during the simulation. Other relevant parameterization schemes and emission datasets have been listed in Tab. A1 and are mostly based on Bromwich et al. (2013).

#### 2.1.1 Nudging to ECMWF ERA5

The first WRF simulation, without any adjustments to O<sub>3</sub> deposition, indicated that WRF was misrepresenting the temporal variability in surface O<sub>3</sub> observations, most prominently starting from a few days into the simulation. We hypothesize that ~~these~~  
155 ~~deviations are this misrepresentation is~~ caused by deviations in the synoptic conditions in the free running WRF simulation. ~~To verify this~~ [Hence](#), WRF results are compared against the observations from the Advanced Microwave Scanning Radiometer - Earth Observing System (AMSR-E) sensor on NASA's Aqua satellite. The near surface wind speeds above oceans from the Daily Level-3 data product are used with a spatial resolution of 0.25°×0.25° (Wentz and Meissner, 2004).

Figure 2 shows the temporal evolution in the bias (WRF minus AMSR-E) and Mean Absolute Error (MAE) of the daily and  
160 ocean grid box averaged 10-m wind speeds. ~~The~~ [Although the](#) first days there is no clear bias. ~~However~~, later in the simulation

**Figure 1.** WRF domain including sea ice and snow cover at the start of the simulation. Locations with surface observations  $O_3$  are indicated in green (High Arctic), magenta (Remote) and cyan (Terrestrial) (see Sect. 2.3). The drifting path of the ASCOS campaign during the simulation is indicated with the black line.

we find a persistent positive wind speed bias indicating that WRF overestimates the wind speeds above the Arctic ocean. During the first days the MAE amounts to  $\sim 1.5 \text{ m s}^{-1}$ , while later in the simulation the MAE reaches  $2.5\text{-}3.0 \text{ m s}^{-1}$ . To overcome the impact of this deficiency on our  $O_3$  budget study, nudging is applied to ensure a fair model evaluation with observations. Hence, WRF is nudged every three hours to the ECMWF ERA5 humidity, temperature and wind fields in the free troposphere with nudging coefficients of  $1 \cdot 10^{-5} \text{ s}^{-1}$ ,  $3 \cdot 10^{-4} \text{ s}^{-1}$  and  $3 \cdot 10^{-4} \text{ s}^{-1}$ , respectively. In Sect. 3.3 the role-impact of nudging on simulated surface  $O_3$  is further analysed.

## 2.2 Representation of ocean-atmosphere gas exchange

The Coupled Ocean-Atmosphere Response Experiment (COARE) (Fairall et al., 1996) has been developed to study physical exchange processes (sensible heat, latent heat and momentum) at the ocean-atmosphere interface. Later, COARE has been extended to include the exchange of gaseous species such as  $O_3$ , dimethyl sulfide (DMS) and carbon dioxide ( $CO_2$ ) (Fairall et al., 2011). Many studies have used the COARE Gas transfer algorithm (COAREG) in combination with eddy covariance measurements to study the effects of wind speed and sea state on ocean-atmosphere gas exchange (e.g. Helmig et al. (2012), Blomquist et al. (2017), Bell et al. (2017), Porter et al. (2020)). Furthermore, the COAREG algorithm has also been previously used in global  $O_3$  modelling studies Ganzeveld et al. (2009). The choice for COAREG as ocean-atmosphere exchange param-

**Figure 2.** Temporal evolution of the bias (WRF minus AMSR-E, black) [ $\text{m s}^{-1}$ ] and Mean Absolute Error (MAE, red) [ $\text{m s}^{-1}$ ] of 10-m wind speeds above oceans for the period of 11-Aug to 6-Sep 2008. Note that the right y-axis starts at  $1.4 \text{ m s}^{-1}$ .

175 eterization is further motivated by the consistent coupling with other species such as DMS.  
 Here we use COAREG version 3.6, which is extended with a two-layer scheme for surface resistance compared to the previous  
 version described by Fairall et al. (2007, 2011). ~~COAREG version 3.6 has already been used in a study by Porter et al. (2020)~~  
~~on air-sea transfer of highly soluble species.~~ The two-layer scheme is similar to ~~the work by~~ Luhar et al. (2018) building upon  
 a first application of a 1-layer version of COAREG ~~for oceanic  $\text{O}_3$  deposition in a global modelling study~~ by Ganzeveld et al.  
 180 (2009). In that study, chemical enhancement of ocean  $\text{O}_3$  deposition by its reaction with iodide was considered using a global  
 climatology of ocean surface water concentrations of nitrate serving as a proxy for oceanic iodide concentrations ( $\Gamma_{\text{aq}}$ ), the  
 compound that is generally deemed to be the most significant reactant for  $\text{O}_3$  in ocean water (Chang et al., 2004). Besides  
nitrate, satellite-derived chlorophyll- $\alpha$  concentrations have been used as a proxy for  $\Gamma_{\text{aq}}$  (Oh et al., 2008). Since then, alterna-  
 tive parameterizations of oceanic  $\Gamma_{\text{aq}}$  have been proposed (e.g. MacDonald et al., 2014) using SST as a proxy for this reactant.  
 185 In COAREG, chemical reactivity of  $\text{O}_3$  with  $\Gamma_{\text{aq}}$  is present through the depth of the oceanic mixing layer.  $\text{O}_3$  loss by waterside  
 turbulent transfer is negligible in the top water layer (few micrometers), but is accounted for in the underlying water column.  
 The waterside turbulent transfer term is especially relevant for relatively cold waters because the chemical enhancement term is  
 then relatively low (Fairall et al., 2007; Ganzeveld et al., 2009; Luhar et al., 2017). The last two important waterside processes  
 that determine the total  $\text{O}_3$  deposition are molecular diffusion and solubility of  $\text{O}_3$  in seawater which both depend on the SST.  
 190 In Appendix B we list the formulation of the air- and waterside resistance terms in the COAREG routine applied in this study

and show the sensitivity to the environmental factors wind speed, SST and  $\Gamma_{aq}$  for typical Arctic conditions.

In this study, the COAREG algorithm is coupled such that WRF provides the meteorological and SST input for the COAREG routine. In turn, the COAREG calculated ocean-atmosphere exchange velocities are used in the WRF model to calculate the ~~total flux. This study focuses on the exchange, in this case deposition, of  $O_3$ . The oceanic  $O_3$  deposition fluxes replace the default flux replacing the default oceanic  $O_3$  deposition fluxes calculated by the Wesely (1989) scheme reflecting use of the default constant  $r_s$  of  $2000 \text{ s m}^{-1}$ .~~ For grid boxes with fractional sea ice cover, COAREG replaces the Wesely deposition scheme for the fraction that is ice free. Note that in this study, only  $O_3$  ocean-atmosphere exchange is represented by COAREG not having modified simulations of ocean-atmosphere exchange of other compounds (e.g. DMS).

Moreover, we apply the monthly-mean  $\Gamma_{aq}$  distribution by Sherwen et al. (2019) ( $0.125^\circ \times 0.125^\circ$  resolution). ~~This distribution does not only depend on SST, but which~~ applies a machine learning approach, namely the Random Forest Regressor algorithm (Pedregosa et al., 2011), using various physical and chemical variables ~~For such as SST, nitrate and chlorophyll- $\alpha$ .~~ This distribution replaces the previously applied  $\Gamma_{aq}$  estimations only using SST (Chance et al., 2014; MacDonald et al., 2014). At high latitudes, ~~this implies higher these  $\Gamma_{aq}$  and thus higher~~ distributions are highly uncertain due to the limited number of observations. However, the choice for Sherwen et al. (2019) is motivated by the most accurate representation of observed  $\Gamma_{aq}$  on the global scale. Figure C1 shows the spatial distribution of  $\Gamma_{aq}$  used in the calculation of the  $O_3$  deposition ~~compared to MacDonald et al. (2014). In that study~~ velocities of COAREG coupled to the WRF model. Using the Sherwen et al. (2019) distribution for August/September we found relatively high  $\Gamma_{aq}$  concentrations ranging between 30 nM and 80 nM for the open oceans up to 130 nM in coastal waters. In MacDonald et al. (2014) and Chance et al. (2014),  $\Gamma_{aq}$  is solely a function of SST which leads to ~~very small  $\Gamma_{aq}$  in the cold Arctic ocean order of 5 to 50 nM~~ and thus low reactivity and  $O_3$  deposition velocities. ~~As mentioned previously, the study by Ganzeveld et al. (2009) also considered the potentially important enhancement in oceanic  $O_3$  deposition by its reaction with DOM, a feature not considered in studies by Luhar et al. (2017); Pound et al. (2019). In Sect. 4 we will discuss the potential role of DOM in our simulations and Arctic  $O_3$  deposition.~~

### 2.2.1 Deposition to snow and ice

Reported atmosphere-snow gas exchange spans a wide range of observed  $O_3$  deposition velocities. Some studies even report episodes of negative deposition fluxes (emissions) over snow or sea ice (Zeller, 2000; Helmig et al., 2009; Muller et al., 2012). Clifton et al. (2020b) recently summarized observed  $O_3$  deposition velocities to snow having a range of  $-3.6$  to  $1.8 \text{ cm s}^{-1}$  with most of the observations indicating a deposition velocity between 0 and  $0.1 \text{ cm s}^{-1}$  for multiple snow covered surfaces (e.g. grass/forest/sea-ice). Generally, ozone concentrations in the interstitial air of the snowpack is lower than in the air above making it a not a direct source of  $O_3$  in terms of emissions (Clifton et al., 2020b). However, the emissions of  $O_3$  precursors from the snowpack can enhance  $O_3$  production in the very stable atmosphere above the snowpack (Clifton et al., 2020b). Helmig et al. (2007a) investigated the sensitivity of a chemistry and tracer transport model to the prescribed  $O_3$  deposition velocity and found best agreement between modelled and observed  $O_3$  concentrations by applying deposition velocities in the order of  $0.00$ - $0.01 \text{ cm s}^{-1}$ . Based on Following Helmig et al. (2007a) we have increased the  $O_3$  surface uptake resistance ( $r_s$ ) for snow and ice land use classes to  $10^4 \text{ s m}^{-1}$ . This corresponds to total deposition velocities of  $\leq 0.01 \text{ cm s}^{-1}$ , which is a reduction of

225 ~66% compared to the Wesely deposition routine that is the default being applied in WRF ([Grell et al., 2005](#)). Effects of this modification are further examined in Sect. 3.1.

### 2.3 Observational data of surface ozone

The new modelling setup, including nudging to ECMWF ERA5 and the revised O<sub>3</sub> deposition to snow, ice and oceans, is evaluated against observational data of pan-Arctic surface O<sub>3</sub> [concentrations](#). We expect that the different representation of  
230 O<sub>3</sub> deposition mostly affects O<sub>3</sub> concentrations in the ABL. Therefore, we evaluate our simulations against hourly averaged surface O<sub>3</sub> observations from 25 measurement sites above 60 °N. These sites are further categorized in three site selections: 'High Arctic', 'Terrestrial' and 'Remote'. High Arctic refers to sites having latitudes > 70 °N and for which we expect that the deposition footprint is a combination of ocean and ~~(sea-)ice~~[sea-ice](#) (e.g. [Helmig et al., 2007b](#)). The Terrestrial sites are located below 70 °N and show a clear diurnal cycle in observed O<sub>3</sub> (e.g. [Chen et al., 2018](#)). These diurnal cycles are governed by  
235 a combination of emissions of precursors, but also the anticipated larger diurnal cycle in O<sub>3</sub> deposition ([Zhou et al., 2017](#)) to, e.g., vegetated surfaces and a stronger diurnal cycle in turbulent mixing conditions and ABL dynamics. These are in all aspects different from sites that have an ocean/~~ice~~[sea-ice](#) footprint where we expect low emissions of precursors, no clear diurnal cycle in O<sub>3</sub> deposition and a weaker diurnal cycle in ABL dynamics ([Van Dam et al., 2015](#)). In this study, the criterion is that the average observed minimum nighttime mixing ratio is > 8 ppb smaller than the average observed maximum daytime  
240 mixing ratio during the ~1 month of simulation. This criterion is based on a preparatory analysis of the observational data, footprint and site characteristics. The Remote sites ~~are located~~[have been identified as such based on their location](#) below 70 °N and ~~at which showing~~ no clear diurnal cycle ~~is observed in~~ [O<sub>3</sub> concentrations](#). The analysis also includes the observations during the Arctic Summer Cloud Ocean Study (ASCOS) campaign, when the icebreaker Oden was located in the Arctic sea ice (Tjernstrom et al., 2012). In total, 25 surface O<sub>3</sub> measurement sites are included (Fig. 1) of which 6, 8 and 11 sites are  
245 characterized High Arctic, Remote and Terrestrial sites, respectively. A full list of available measurement sites is available in Tab. D1.

### 2.4 Overview of performed simulations

In total, we perform three simulations. The first WRF simulation (DEFAULT) is a run without any adjustments to the code as described in Sect. 2.1. The second simulation (NUDGED) includes nudging of the synoptic conditions to the ECMWF ERA5  
250 product as described in Sect. 2.1.1. The third simulation (COAREG) includes nudging, but also includes the adjustments to the O<sub>3</sub> deposition to oceans as described in Sect. 2.2 and the O<sub>3</sub> deposition to snow and ice as described in Sect. 2.2.1. Furthermore, we also compare our results with the the state-of-the-art CAMS global reanalysis data product (Inness et al., 2019). This product has a temporal resolution of 3 hours, a spatial resolution of 0.75° × 0.75° ~~;~~ and does not include a mechanistic representation of ocean-atmosphere O<sub>3</sub> exchange. ~~Regarding O<sub>3</sub>,~~ CAMS assimilates satellite observations [of O<sub>3</sub>](#) but it does not assimilate  
255 O<sub>3</sub> observations from [radiosondes or](#) in situ measurement sites ~~or radiosondes~~[such as the 25 sites used in the here presented evaluation](#). Moreover, CAMS is being widely used for air quality forecasts and assessments but also to constrain regional scale modelling experiments such as presented in this study.

### 3 Results

260 First, we will present the spatial and temporal variation in  $O_3$  dry deposition velocities ( $V_{d,O_3}$ ) of the ~~new and default~~ NUDGED and COAREG modelling setup including the effect on the total  $O_3$  deposition budget. Subsequently we will discuss the resulting effect on the spatial distribution of the mean ~~background~~ surface  $O_3$  mixing ratios. Then, we will present the comparison of all WRF simulations and CAMS data with the hourly surface observations for the three site selections (High Arctic, Remote and Terrestrial). This section is finalized by the simulated and observed time series for the six High Arctic sites.

#### 3.1 Dry deposition budgets and distribution

265 Figure 3a and Fig. 3b show the mean deposition velocities for the ~~DEFAULT~~ NUDGED and COAREG runs, respectively. As expected, in the ~~DEFAULT~~ NUDGED run (Fig. 3a) the mean  $V_{d,O_3}$  to oceans are in the order of  $0.05 \text{ cm s}^{-1}$ . Furthermore, the spatial distribution shows a relatively low heterogeneity and no increase in deposition velocities towards the warmer waters. ~~In the~~ The COAREG run (Fig. 3b) ~~we find provides a~~ mean  $V_{d,O_3}$  in the order of  $0.01 \text{ cm s}^{-1}$  for the ~~colder waters~~ Arctic ocean  $> 70^\circ\text{N}$  up to  $0.018 \text{ cm s}^{-1}$  for ~~the warmer waters. There also appears to be an enhancement of oceans with high~~  $I_{\text{aq}}$  concentrations (Fig. C1). Simulated oceanic  $O_3$  deposition ~~to is elevated in~~ coastal waters (e.g. Baltic Sea and around the Bering Strait) with  $I_{\text{aq}}$  concentrations reaching up to  $130 \text{ nM}$  compared to ~~30-30-50~~  $30-50 \text{ nM}$  for the open Arctic ocean waters (~~not shown here~~ Fig. C1). This highlights the sensitivity of the COAREG scheme to chemical enhancement with dissolved iodide.

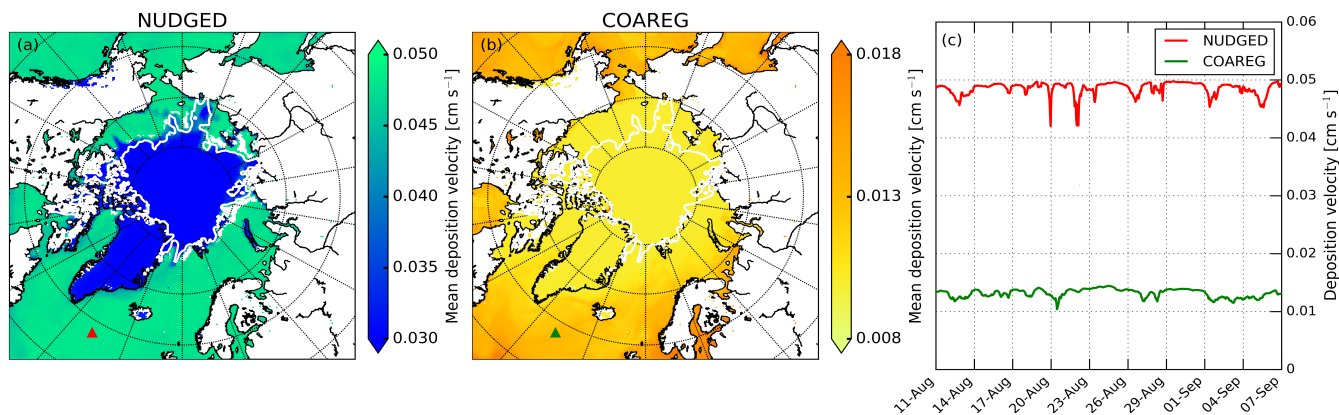

270 Figure 3c shows the temporal variability in  $V_{d,O_3}$  for one of the grid boxes, which is in terms of temporal variability representative for the whole domain. The temporal variability in the ~~DEFAULT run is~~ NUDGED run is mainly governed by temporal variability in  $r_a$ . During episodes with high wind speeds ( $> 10 \text{ m s}^{-1}$ ),  $r_a$  becomes so small that it is negligible over the constant surface uptake resistance of  $2000 \text{ s m}^{-1}$ , corresponding to a maximum  $V_{d,O_3}$  of  $0.05 \text{ cm s}^{-1}$ . During episodes with low wind speeds ( $< 5 \text{ m s}^{-1}$ ), reduced turbulent transport poses some additional restriction on  $O_3$  removal with increasing  $r_a$  which ~~can reduce~~ reduces the  $V_{d,O_3}$  ~~up to~~  $\sim 8\%$   ~~$0.04 \text{ cm s}^{-1}$~~ . In the COAREG run, ~~the~~ temporal variability in  ~~$O_3$  deposition~~  $V_{d,O_3}$  is also governed by wind speeds that controls the waterside turbulent transport of  $O_3$  in seawater besides atmospheric turbulent transport. For high wind speeds, the waterside turbulent transport increases (Fig. B1) and more  $O_3$  is transported through the turbulent layers. For our simulation, we found that the temporal variability in  $O_3$  deposition due to waterside turbulent transport can be up to  $\pm 20\%$  around the mean. Overall, the  $V_{d,O_3}$  to oceans in the COAREG run is reduced by  $\sim 60-80\%$  compared to the ~~DEFAULT~~ NUDGED run. The mean  $V_{d,O_3}$  to snow and ice is reduced by  ~~$\sim 30$~~   $66\%$ , from  $\sim 0.03 \text{ cm s}^{-1}$  in the ~~DEFAULT~~ NUDGED run to  $\sim 0.01 \text{ cm s}^{-1}$  in the COAREG run.

285 The temporal evolution in oceanic  $O_3$  deposition velocities simulated by the COAREG run appears to be on the low side of observed and elsewhere simulated  $V_{d,O_3}$  (e.g. Chang et al., 2004; Oh et al., 2008; Ganzeveld et al., 2009). Chang et al. (2004) showed that  $V_{d,O_3}$  can increase by a factor of 5 with wind speed increasing from 0 to  $20 \text{ m s}^{-1}$ . Luhar et al. (2017) (Figure 7) shows a wide range of observed and simulated sensitivities to wind speed. Observations from the TexAQS06 summer campaign in the Gulf of Mexico show a large sensitivity to 10-meter wind speeds even though the model seems unable to  
290 capture these high deposition velocities at high wind speeds (Luhar et al., 2017). However, Luhar et al. (2017) also shows

that for the GasEx08 campaign in the cold Southern Ocean the sensitivity of observed and simulated  $V_{d,O_3}$  to 10-meter wind speeds is very limited. This limited sensitivity is most accurately represented by the newer two-layer reactivity scheme compared to the older one-layer scheme due to a more limited interaction between chemical reactivity and waterside turbulent transport (Luhar et al., 2017). Furthermore, the variability around the mean presented in Tab. 1 ( $0.012 \pm 0.002 \text{ cm s}^{-1}$ ) seems to correspond to Oh et al. (2008) ( $0.016 \pm 0.0015 \text{ cm s}^{-1}$ ) 1 month simulation including  $O_3$  removal by  $\Gamma_{aq}$ . In this study we show the intramonthly variability in oceanic  $O_3$  deposition which is expected to be relatively low compared to the seasonal variability which will also be driven by temporal changes in solubility and reactivity due to the seasonal changes in SST and  $\Gamma_{aq}$ .

By estimating the total deposition flux for the water, snow/ice and land surfaces we can quantify the total simulated  $O_3$  deposition budget (Tab. 1) for the Arctic modelling domain. Land, not covered with snow or ice, is with 48% the dominant surface type for this specific domain setup in summer. Combined with a relatively high simulated  $V_{d,O_3}$  of  $\sim 0.45 \text{ cm s}^{-1}$  this is the most important sink, in terms of deposition, of simulated  $O_3$  with  $\sim 136\text{--}135 \text{ Tg } O_3 \text{ yr}^{-1}$ . The simulated  $O_3$  deposition budget to water bodies, covering 37% of the total surface area, is in the DEFAULT contributes in the NUDGED run  $\sim 10\%$  ( $\sim 15.5\text{--}15.4 \text{ Tg } O_3 \text{ yr}^{-1}$ ) of to the total  $O_3$  deposition sink. In the COAREG run, this reduces to only  $\sim 3\%$  ( $\sim 4.6 \text{ Tg } O_3 \text{ yr}^{-1}$ ) of the total  $O_3$  deposition sink. Simulated  $O_3$  deposition to snow and ice, covering 15% of the total surface area, is the least important deposition sink with  $\sim 4.1$  and  $\sim 1.7 \text{ Tg } O_3 \text{ yr}^{-1}$  for in the DEFAULT and COAREG runs respectively.

**Figure 3.** Spatial distribution of the mean simulated  $O_3$  deposition velocity to snow/ice and oceans [ $\text{cm s}^{-1}$ ] for the (a) ~~DEFAULT~~ NUDGED and (b) COAREG simulations and (c) temporal variation in  $O_3$  deposition velocity [ $\text{cm s}^{-1}$ ] for the ~~DEFAULT~~ NUDGED (red) and COAREG (green) simulations. The red and green markers in (a) and (b) indicate the location of the time series shown in (c). To give an indication of the sea ice extent, the white contours show the sea ice fraction of 0.5 at the start of the simulation.

### 3.2 Simulated and observed monthly mean surface ozone

The reduction in  $O_3$  deposition to water and snow/ice surfaces, comparing the DEFAULT and COAREG simulation results (Sect. 3.1, Tab. 1), appears to be limited in terms of relative changes in  $V_{d,O_3}$  and the total simulated  $O_3$  deposition budget.

**Table 1.** Mean simulated O<sub>3</sub> deposition velocity ( $\pm$ Standard deviation) [cm s<sup>-1</sup>] and total simulated deposition budget [Tg O<sub>3</sub> yr<sup>-1</sup>] for the ~~DEFAULT~~-NUDGED and COAREG runs to water, snow/ice and land each representing 37%, 15% and 48% of the total surface area respectively. The standard deviation gives an indication of the spatiotemporal variability in simulated O<sub>3</sub> deposition velocities.

		Water (37%)	Snow/Ice (15%)	Land (48%)	Total (100%)
NUDGED	Deposition velocity ( $\pm$ Std.) [cm s <sup>-1</sup> ]	<del>0.048</del> <u>0.047</u> ( $\pm$ 0.003)	0.030 ( $\pm$ 0.000)	0.449 ( <del><math>\pm</math>0.23</del> <u><math>\pm</math>0.225</u> )	
	Deposition budget [Tg O <sub>3</sub> yr <sup>-1</sup> ]	<del>15.5</del> <u>15.4</u>	4.1	<del>132.9</del> <u>133.4</u>	<del>152.5</del> <u>152.9</u>
COAREG	Deposition velocity ( $\pm$ Std.) [cm s <sup>-1</sup> ]	0.012 ( $\pm$ 0.002)	0.010 ( $\pm$ 0.000)	0.448 ( $\pm$ 0.251)	
	Deposition budget [Tg O <sub>3</sub> yr <sup>-1</sup> ]	4.6	1.7	135.8	142.1

310 ~~Epecially contrasting this with the previously mentioned up to  $\sim$ 2 orders of magnitude larger  $V_{d,O_3}$  to vegetation. However, these relatively small changes do significantly affect the spatial and temporal variation of simulated surface O<sub>3</sub> mixing ratios.~~ Figure 4 shows the spatial distribution in the simulated mean surface O<sub>3</sub> mixing ratios overlain with the observed mean surface O<sub>3</sub> mixing ratios. In the ~~DEFAULT~~-NUDGED and COAREG runs (Fig. 4a and Fig. 4b respectively) we find similar ~~background surface~~ O<sub>3</sub> mixing ratios of  $\sim$ 15-20 ppb over the Russian and Canadian/Alaskan land masses. Over Scandinavia, slightly higher ~~background surface~~ O<sub>3</sub> mixing ratios of  $\sim$ 20-25 ppb are simulated due to more anthropogenic emissions of precursors in the EDGAR emission inventory and advection of O<sub>3</sub> and its precursors from outside the domain. ~~We As expected, we~~ find a limited effect of reduced deposition to water and snow/ice to the simulated mean O<sub>3</sub> mixing ratios over land. In general, the model appears to ~~be able to~~ simulate the mean observed surface O<sub>3</sub> mixing ratios for the Remote and Terrestrial sites (all sites < 70 °N) ~~generally well~~ without clear positive or negative bias. ~~However, we~~ Due to the altitude effect higher surface O<sub>3</sub> concentrations are simulated over Greenland even though the deposition velocity to snow and the surrounding oceans is of similar magnitude ( $\sim$ 0.01 cm s<sup>-1</sup>).

The reduced O<sub>3</sub> deposition to water and snow/ice surfaces, comparing the NUDGED and COAREG simulation results (Sect. 3.1, Tab. 1), appears to be limited in terms of relative changes in  $V_{d,O_3}$  and the total simulated O<sub>3</sub> deposition budget. However, these relatively small changes do substantially affect the simulated spatial distribution of surface O<sub>3</sub> mixing ratios over oceans and sea ice as indicated in Fig. 4. We find that the ~~DEFAULT~~-NUDGED run (Fig. 4a) systematically underestimates the mean observed surface O<sub>3</sub> mixing ratios for the High Arctic sites (all sites > 70 °N) by  $\sim$ 5-10 ppb ~~likely which appears to be~~ caused by an overestimated deposition to ocean, snow and ice surfaces. ~~also further substantiated by the following analysis of short-term variability in O<sub>3</sub> concentrations (Sect. 3.3).~~ Over the Arctic sea ice and oceans the ABL is typically very shallow and atmospheric turbulence is relatively weak. This suppresses vertical mixing and entrainment of O<sub>3</sub> rich air from the free troposphere. Dry deposition of O<sub>3</sub> to the ocean or snow/ice surfaces appears to be an important removal mechanism that has a large impact on O<sub>3</sub> concentrations in these shallow ABLs (Clifton et al., 2020a) both in terms of magnitude but also temporal variability as we will show in Sect. 3.4. In the COAREG run, the ~~background surface~~ O<sub>3</sub> mixing ratios over oceans and Arctic sea ice have increased up to 50%. Furthermore, the reduced deposition to snow/ice has also clearly affected simulated surface O<sub>3</sub> mixing ratios over Greenland. Most importantly, the negative bias in simulated surface O<sub>3</sub> mixing ratios is reduced in the COAREG run with respect to the ~~DEFAULT run. This is further examined in~~ NUDGED run (see Sect. 3.3). ~~The CAMS~~

325  
330  
335

reanalysis data appears to simulate higher (up to 10 ppb) surface  $O_3$  mixing ratios over land than the two WRF runs. Over sea ice, the magnitude of simulated surface  $O_3$  mixing ratios in CAMS is in between the DEFAULT and COAREG runs. Over Greenland, CAMS simulates mixing ratios of  $\sim 40$  ppb, with a sharp gradient towards the coast. This gradient is less pronounced in the WRF simulations. Both CAMS and WRF appear to underestimate the mean observed ( $\sim 45$  ppb) surface  $O_3$  mixing ratios at Summit. The frequency distributions (Fig. 4d) also show that relatively high (25–45 ppb) simulated surface  $O_3$  mixing ratios are more frequent in COAREG and CAMS compared to the DEFAULT and NUDGED runs.

**Figure 4.** Spatial distribution of the simulated mean surface  $O_3$  mixing ratio [ppb] for the (a) ~~DEFAULT~~ NUDGED and (b) COAREG runs ~~and~~ (c) CAMS data and (d) frequency distributions of surface  $O_3$  mixing ratios ppb over the entire simulation and domain for the DEFAULT (red), NUDGED (yellow), COAREG (green) runs and CAMS data (blue). The filled circles indicate the mean observed ozone mixing ratios [ppb] for the simulated period. To indicate the sea ice extent, the white contours show the sea ice fraction of 0.5 at the start of the simulation.

### 3.3 Simulated and observed hourly surface ozone

In this section we show how both nudging and the application of the revised deposition scheme ~~can especially improve~~ short-term variability in improves the model prediction scores of surface  $O_3$  concentrations reflected in a comparison of the simulated and observed hourly surface  $O_3$  mixing ratios at the three site selections (High Arctic, Remote and Terrestrial). This is according to our knowledge the first time such ~~a~~ an oceanic  $O_3$  deposition scheme coupled to a meteorology-chemistry model is evaluated against a large dataset of hourly surface  $O_3$  observations. Figure 5 shows a comparison between observed and simulated hourly surface  $O_3$  mixing ratios subdivided in the three site selections: High Arctic, Remote and Terrestrial. ~~For~~ As expected, for the High Arctic sites (Fig. 5, top row) we ~~again~~ find that the DEFAULT run is underestimating the observed surface  $O_3$  mixing ratios with a mean bias of -7.7 ppb. ~~This is consistent to findings in Fig. 4, where the DEFAULT run appears~~

~~to underestimate surface O<sub>3</sub> mixing ratios in the High Arctic region.~~ Interestingly, nudging to ERA5 wind, temperature and humidity appears to already reduce some of the bias in the High Arctic by better representing the temporal variability in surface O<sub>3</sub>. This is further examined in Sect. 3.4. However, the NUDGED run appears to still underestimate High Arctic surface O<sub>3</sub> with a bias of -3.8 ppb ~~-which is also consistent with the findings in Fig. 4, where the NUDGED run appears to underestimate~~  
355 ~~surface O<sub>3</sub> mixing ratios in the High Arctic region.~~ The COAREG run, having a reduced O<sub>3</sub> deposition sink to oceans and snow/ice appears to better represent the ~~background~~-surface O<sub>3</sub> observations with a slight positive bias of 0.3 ppb. The MAE in the COAREG run is reduced to 4.7 ppb from 8.5 and 6.4 for the DEFAULT and NUDGED runs respectively. Furthermore, we find that the CAMS reanalysis data also underestimates surface O<sub>3</sub> in the High Arctic with a bias of -5.0 ppb and a MAE of 6.8 ppb. ~~It has to be noted~~ Note that the performance for all WRF runs and CAMS reanalysis product is varying for each  
360 observational site which is further examined in Sect. 3.4.

For the Remote sites (Fig. 5, middle row), having no clear diurnal cycle in surface O<sub>3</sub>, we find again an improvement by nudging the WRF model to ERA5 and also by including the mechanistic ocean deposition routine and reduced snow/ice deposition. This improvement appears to be most pronounced for coastal sites like Storhofdi (63.4°N,20.3°W) and Inuvik (68.4°N,133.7°W) ~~having with~~ a reduction in the MAE of 57% and 36% respectively (not shown here). Overall, the improve-  
365 ment for the NUDGED and COAREG runs compared to the DEFAULT run in the Remote site selection is not as significant compared to the High Arctic sites, ~~probably also~~ because of the larger role of O<sub>3</sub> deposition to land and vegetation, which remained unchanged in this study. We find that the CAMS data shows the best performance for the Remote sites with no bias and with a MAE of 5.6 ppb.

For the Terrestrial sites (Fig. 5, bottom row), having a clear diurnal cycle in surface O<sub>3</sub>, all WRF runs slightly overestimate  
370 the observed surface O<sub>3</sub> mixing ratios with a mean bias up to 1.0 ppb. By nudging WRF to ERA5 the bias is reduced from 7.0 ppb to 6.0 ppb. Reducing the O<sub>3</sub> deposition to oceans and snow/ice increases the bias, but the MAE remains unchanged. The CAMS reanalysis data appears to perform worst for the Terrestrial sites with a bias of 6.4 ppb and a MAE of 8.0 ppb. This might be explained by the lower spatial and temporal resolution ~~in the dataset of CAMS specifically~~ at these sites ~~with~~  
375 ~~having~~ a relatively strong diurnal cycle in ABL dynamics ~~and O<sub>3</sub> concentrations.~~ ~~Interestingly, of all the combinations, we find~~  
~~the largest MAE (8.5 ppb) for the High Arctic sites in the DEFAULT run (Fig. 6a) while we find the lowest MAE (4.7 ppb)~~  
~~for the High Arctic sites in the COAREG run (Fig. 6c).~~ This indicates the high sensitivity of the adjusted ocean, snow and ice  
~~surfaces deposition representation to the magnitude and temporal variability in surface O<sub>3</sub> at high latitudes. Because these sites~~  
~~are located far away from the domain boundaries we expect that these model results are to a lesser extent influenced by the~~  
~~boundary conditions compared to the Terrestrial and Remote sites and therefore more sensitive to the~~ O<sub>3</sub> ~~deposition scheme~~  
380 ~~in WRF to vegetation and O<sub>3</sub> concentrations. Also a misrepresentation of emissions of precursor emissions and concentrations~~  
~~and the O<sub>3</sub> deposition to vegetation (Michou et al., 2005; Val Martin et al., 2014) might explain some of the differences.~~

### 3.4 ~~Temporal~~ Short-term temporal variability of surface ozone in the High Arctic

In Sect. 3.3 we have shown how nudging the WRF model to ERA5 synoptic conditions and revising the O<sub>3</sub> deposition scheme to oceans and snow/ice can improve the model's capability to represent the observed hourly surface O<sub>3</sub> mixing ratios, especially

**Figure 5.** Comparison of the hourly observed and simulated ozone mixing ratios [ppb] for the DEFAULT (a,e,i), NUDGED (b,f,j), COAREG (c,g,k) runs and CAMS data (d,h,l) for the High Arctic (HA) (a-d), Remote (RE) (e-h) and Terrestrial (TE) (i-l) sites. The red line indicates the 1:1 line and the black line indicates the Ordinary Least Squares regression line through the origin. The number of data points (n), Bias [ppb] and Mean Absolute Error (MAE) [ppb] are shown in the top left corner. The colors represent the multivariate kernel density estimation with yellow colors having a higher density.

385 for the High Arctic sites. In this section we show how the ~~three WRF-NUDGED and COAREG~~ runs and CAMS represent the temporal variation in High Arctic surface O<sub>3</sub> observations, focusing on a ~~selection-6 out~~ of the 25 measurement sites. These 6 High Arctic sites have been selected due to their deposition footprint being dominated by transport over, and deposition to, ocean and sea-ice covered surfaces. Figure 6 shows the observed and simulated surface O<sub>3</sub> time series for ~~the 6 High Arctic (>70°N) sites:~~ ASCOS, Summit, Villum, Zeppelin, Barrow and Alert. Furthermore, Tab. 2 shows the model skill indicators for  
390 the High Arctic sites. These skill indicators include the Mean Absolute Error (MAE) that represents the systematic error, the Standar Deviation of Observation minus model Prediction  $\sigma_{o-p}$  that represents the random error and the Pearson-R correlation coefficient (R) that represents the degree of correlation.

The observations at ASCOS (Fig. 6a) show a sudden increase of surface O<sub>3</sub> mixing ratios from 20 to over 30 ppb around the 17<sup>th</sup> of August due to advection of relatively ozone rich air during a synoptically active period (Tjernstrom et al., 2012).  
395 Only the COAREG run appears to be able to simulate a similar increase in surface O<sub>3</sub> while NUDGED and CAMS show a minor increase ~~and the DEFAULT run shows no increase~~ in simulated surface O<sub>3</sub> ~~at all~~. From the 17<sup>th</sup> of August onwards, the observations show mixing ratios between 25 and 35 ppb. The WRF simulations indicate advection of air over ocean and ice surfaces during this time period (not shown here). In the COAREG simulation, with less deposition to these surfaces, surface O<sub>3</sub> mixing ratios are less depleted. Only the COAREG run is able to represent these observed mixing ratios with a bias of -2.0  
400 ppb whereas the ~~other models simulate~~ NUDGED and CAMS are clearly biased towards lower mixing ratios.

At Summit (Fig. 6b), we find a large temporal variability in observed surface O<sub>3</sub> between 30 and 55 ppb. From the 11<sup>th</sup> of August onwards we find a decreasing trend in observed surface O<sub>3</sub> down to 30 ppb before increasing to 40 ppb around the 17<sup>th</sup> of August. ~~We find that the DEFAULT run is unable to~~ All models capture this specific event ~~whereas the NUDGED and COAREG runs already appear to capture this event much better~~ in terms of temporal variability even though ~~the model is~~  
405 NUDGED and COAREG are still biased at the observed minimum of 30 ppb. Furthermore, we find that the CAMS reanalysis data represents this specific period very well, also in terms of magnitude. At Summit, the increase of surface O<sub>3</sub> in the COAREG run relative to the NUDGED run mostly reflects the reduction of deposition to snow and ice due to the prevailing katabatic wind flow (Gorter et al., 2014). During episodes with low wind speeds the ABL becomes very stable and shallow during which deposition to snow and ice becomes an important process in removing O<sub>3</sub> in the ABL. In the period between the 14<sup>th</sup> and 26<sup>th</sup>  
410 of August this reduction in deposition can increase the surface O<sub>3</sub> mixing ratios up to 10 ppb (e.g. 23<sup>th</sup> of August). In contrast, during episodes with higher wind speeds and deeper ABLs the reduced O<sub>3</sub> deposition to snow hardly affects the simulated surface O<sub>3</sub> concentrations. Interestingly, we find that the NUDGED and COAREG simulations show a larger negative bias (~5-10 ppb) during the period with low wind speeds and shallow ABLs. Over the entire simulated period, CAMS performs best at Summit with a MAE of 3.9 ppb followed by COAREG with a MAE of 6.1 ppb. ~~Interestingly,~~

415 Villum (Fig. 6c) is the only site for which the ~~DEFAULT run performs best in terms of bias and MAE. This run slightly underestimates the observed mixing ratios with a bias of -2.4 ppb.~~ The NUDGED and COAREG runs as well as the CAMS reanalysis data all systematically overestimate the observed mixing ratios, especially later into the simulation. The observations show an increase in O<sub>3</sub> mixing ratios from 10 to 20 ppb in the first three days of the simulation where after it remains between 20 and 30 ppb with relatively low temporal variability compared to some of the other sites (e.g. Summit, Barrow). Both the

420 NUDGED and COAREG runs simulate mixing ratios up to 40 ppb and CAMS simulates maximum surface O<sub>3</sub> mixing ratios of 35 ppb. In terms of representing the magnitude of surface O<sub>3</sub> mixing ratios CAMS performs best with a MAE of 4.5.  
Zeppelin (Fig. 6d) and Barrow (Fig. 6e) show similar behaviour in terms of observation-model comparison. For both locations ~~, both the DEFAULT run as well as the~~ the CAMS reanalysis data systematically ~~underestimate~~ underestimates observed ozone mixing ratios with ~~biases larger than a~~ biases > 10 ppb. In the NUDGED run ~~, some of the temporal variability is already better~~  
425 ~~represented by WRF and reduces the bias to~~ the bias equals -6.9 and -4.6 ppb for Zeppelin and Barrow, respectively. In the COAREG run the bias is reduced to -1.0 and -0.2 ppb for Zeppelin and Barrow respectively. ~~From the~~ This reduction in bias is, together with ASCOS, the largest among the 6 High Arctic sites and shows the large sensitivity to the representation of O<sub>3</sub> deposition. At Barrow, the dominant wind directions during the simulation period are NW-NE giving a footprint mostly from the Arctic sea ice and ocean. Especially in the period from the 23<sup>th</sup> of August until the end of the simulation, we find  
430 ~~a good example of the importance of a realistic representation of synoptic conditions by nudging and the role of ocean and snow/ice deposition. In this period, the DEFAULT run and CAMS reanalysis data systematically underestimate the~~ th of August onward the COAREG run is very accurate in representing the magnitude as well as the temporal variability in observed surface O<sub>3</sub> mixing ratios. Moreover, the COAREG run is representing the observed. During this period, the NUDGED run simulates surface O<sub>3</sub> mixing ratios ~~very well, both in terms of magnitude as well as temporal variability up to 5 ppb lower due~~  
435 ~~to the overestimated deposition to oceans and sea ice. At both sites, the model performance of COAREG is in the same order of magnitude with an MAE,  $\sigma_{o-p}$  and R of  $\sim$  3.5 ppb, 4.2 ppb and 0.65 respectively.~~  
At Alert (Fig. 6f), ~~the DEFAULT run again underestimates the~~ we find a relatively steady increase in observed surface O<sub>3</sub> ~~mixing ratios even though the bias of -6.4 ppb is not as large as for~~ from 20 ppb at the start of the simulation to 30 ppb at the end of the simulation. The temporal variability, both in observed and simulated surface O<sub>3</sub> appears to be lower compared to  
440 ~~some of the other sites~~ High Arctic sites. Again, the statistical parameters such as MAE,  $\sigma_{o-p}$  and R improve in the COAREG run with respect to the NUDGED run. This bias, as well as the MAE, is again decreased for the NUDGED and COAREG runs.  
At Alert, we find that CAMS has the lowest MAE and  $\sigma_{o-p}$  of 3.0 ppb ~~, but has a slight negative bias of -1.9 ppb and 3.4 ppb~~ respectively.  
The model performance in terms of temporal variability in surface O<sub>3</sub> observations is diagnosed by using the Pearson-R  
445 correlation coefficient. ~~Nudging the WRF model to ERA5 meteorological data already improved the representation of the temporal variability especially for sites like Barrow and Summit where the synoptic conditions were likely not represented well. This causes an offset in timing of the advection of different air masses but here also vertical mixing and entrainment of O<sub>3</sub> rich air could play a role.~~ The model performance ~~also~~ improved for all six sites in the COAREG run with respect to the NUDGED run. The COAREG run includes temporal variability in O<sub>3</sub> deposition due to variability in waterside turbulent transport which  
450 can explain additional improvements in representing the temporal variability of surface O<sub>3</sub>. The COAREG simulation performs best for 5 out of the 6 observational sites in terms of Pearson-R correlation coefficient and is only outperformed by CAMS at Summit. Overall, we find that ~~nudging reduces the bias and MAE for all High Arctic sites except Summit and Villum by better representing the synoptic conditions and therefore the temporal variability in observed surface O<sub>3</sub>. Coupling the~~ coupling the WRF model to the mechanistic COAREG ocean-atmosphere exchange representation ~~further decreases the bias and MAE~~

455 decreases the MAE and  $\sigma_{O_3}$  for all High Arctic sites except for Villum by better representing the magnitude of, but also temporal variability in observed surface O<sub>3</sub>. The CAMS reanalysis data is performing well for some locations (e.g. Summit, Alert) while for Zeppelin and Barrow the discrepancy is among the largest we found in the observation-model comparison.

**Table 2.** Bias-MAE [ppb], MAE- $\sigma_{O_3}$  [ppb] and Pearson-R correlation coefficient (R) [-] for the DEFAULT, NUDGED and COAREG runs and CAMS reanalysis data at the ASCOS, Summit, Villum, Zeppelin, Barrow and Alert observational sites. The lowest model error and highest correlation have been made bold for every site.

#### 4 Discussion

460 In this study, we demonstrate the role of oceanic O<sub>3</sub> exchange to simulate the magnitude and temporal variability of hourly surface O<sub>3</sub> concentrations in the Arctic region. We show that the model modelled sensitivity of the surface O<sub>3</sub> concentrations to the representation of O<sub>3</sub> to ocean, ice and snow surfaces is high, even though the total deposition budget is an order of magnitude smaller than the deposition to land and vegetation. Using a mechanistic representation of oceanic O<sub>3</sub> deposition to oceans and reducing the representation and reduced O<sub>3</sub> deposition to snow and ice greatly reduced the negative bias in surface O<sub>3</sub>, especially in the high Arctic. Furthermore, the short-term temporal variability in surface O<sub>3</sub> was also better represented by the mechanistic representation of oceanic O<sub>3</sub> deposition by also accounting for temporal variations in the driving processes of oceanic O<sub>3</sub> deposition such as waterside turbulent transport.

Our main objective was to address the role-impact of a mechanistic oceanic O<sub>3</sub> deposition representation, including spatial and temporal variability, on the magnitude and temporal variability of surface O<sub>3</sub> concentrations and to evaluate this with 470 a large dataset of 25 observational sites in and around the Arctic. We show that Arctic surface O<sub>3</sub> concentrations are very sensitive to the representation of O<sub>3</sub> deposition. ~~We did not address include in the presented analysis how the nudging and representation of Arctic O<sub>3</sub> deposition further affects the contribution to the Arctic O<sub>3</sub> budget e.g. by changes in photochemistry and stratosphere-troposphere exchange and advection. For such a budget analysis it would be best to perform at least one year of simulation to also address the seasonal cycles in deposition, photochemistry and long range transport which is computationally~~ 475 too expensive in WRF. Regarding oceanic to oceans and sea-ice especially at coastal sites and sites with latitudes >70°N. At sites with a more terrestrial footprint (e.g. Norway, Sweden, Finland), the comparison of modelled and observed surface O<sub>3</sub> concentrations also shows a discrepancy. As expected, this discrepancy has not been resolved introducing the more mechanistic representation of O<sub>3</sub> deposition oceans and modified snow/sea-ice deposition rate. In terms of deposition, these sites are mostly

**Figure 6.** Temporal evolution of hourly surface  $O_3$  mixing ratios [ppb] for the ~~DEFAULT (red)~~, NUDGED (yellow), and COAREG (green) runs, CAMS data (blue crosses) and observations (black dots) at ASCOS ( $\sim 87.4^\circ N, \sim 6.0^\circ W$ ), Summit ( $72.6^\circ N, 38.5^\circ W$ ), Villum ( $81.6^\circ N, 16.7^\circ W$ ), Zeppelin ( $78.9^\circ N, 11.9^\circ E$ ), Barrow ( $71.3^\circ N, 156.6^\circ W$ ) and Alert ( $82.5^\circ N, 62.3^\circ W$ ).

influenced by  $O_3$  deposition to vegetation and land (e.g. Silva and Heald, 2018; Wong et al., 2019; Clifton et al., 2020b). In the  
480 WRF simulations, dry deposition of  $O_3$  to vegetation (mostly land-use class: 'wooded tundra') amounts to  $\sim 0.2\text{-}1.0\text{ cm s}^{-1}$   
with a clear diurnal cycle. Dry deposition of  $O_3$  to 'bare tundra' is in the order of  $0.1\text{-}0.15\text{ cm s}^{-1}$  which is slightly higher  
than observed by Van Dam et al. (2015). A detailed analysis of  $O_3$  deposition ~~this would also include long-term changes  
in sea ice cover and oceanic biogeochemistry. The major constraint in this model setup is the lack of oceanic to land and  
vegetation is beyond the scope of this study and would require a different strategy, e.g. direct comparison with  $O_3$  flux  
485 measurements (e.g. Van Dam et al., 2016). However, a better understanding and model representation of the drivers of  $O_3$  de-  
position ~~measurements over the Arctic ocean. The COAREG exchange routine has been built and validated using~~ to vegetation  
and land, including the diurnal and seasonal variability of these drivers (Lin et al., 2019), is anticipated to also result in a better  
representation of short-term variability of surface  $O_3$  over land.~~

The COAREG scheme has been developed and validated against eddy-covariance measurements over mostly (sub-)tropical  
490 waters (Bariteau et al., 2010; Helmig et al., 2012). The COAREG routine has been ~~further developed and used~~ applied to  
study the effects of wind speed and sea state on ocean atmosphere gas transfer (Blomquist et al., 2017; Bell et al., 2017;  
Porter et al., 2020). We do expect that these main drivers, being waterside turbulent transfer and chemical enhancement with  
dissolved iodide, ~~held for oceans also controls oceanic  $O_3$  deposition~~ at high latitudes. ~~Using indirect information to evaluate~~  
Indirect evaluation of oceanic  $O_3$  deposition through comparison of surface  $O_3$  observations instead of direct oceanic  $O_3$  flux  
495 measurements ~~we show that the addition of indicates that including~~ this mechanistic representation of  $O_3$  deposition ~~results  
in a better representation of both the improves both the modelled~~ magnitude and temporal variability in surface  $O_3$  observa-  
tions. However, ~~the exact magnitude and variability in Arctic a lack of~~ oceanic  $O_3$  deposition ~~could not be evaluated using  
flux measurements flux measurements hampers the direct model evaluation of the high-latitude  $O_3$  deposition flux. This is  
expected to be soon resolved by getting access to  $O_3$  flux observations collected in the Multidisciplinary drifting Observatory  
500 for the Study of Arctic Climate (MOSAIC) 1-year field campaign.~~

Furthermore, we have reduced the deposition to snow and ice ~~based on a study by Helmig et al. (2007a). The results of that  
study also further following Helmig et al. (2007a) and (Clifton et al., 2020b). Results of Helmig et al. (2007a) also~~ motivated  
follow-up observational and modelling studies aiming at the development of ~~similar to COAREG for oceanic  $O_3$  deposition,~~  
more mechanistic representations of  $O_3$  deposition to snow/ice covered surfaces. For example, efforts have been made to  
505 simulate  $O_3$  dynamics in and above the snowpack using a 1D model setup to ~~evaluate explain~~ observations of  $O_3$  and  $NO_x$   
concentrations measured above and inside the Summit snowpack (Van Dam et al., 2015). This 1D modelling study showed the  
main role of aqueous-phase oxidation of  $O_3$  with formic acid in the snowpack (Murray et al., 2015). Comparable 1D modelling  
studies focused on assessing the role of catalytic ozone loss via bromine radical chemistry in the snowpack interstitial air  
(Thomas et al., 2011; Toyota et al., 2014). However, these studies mainly ~~arrived at conclusions regarding addressed~~ the role  
510 of some of this snowpack chemistry in explaining, partly observed,  $O_3$  concentrations and not so much on snow-atmosphere  
 $O_3$  fluxes and derived deposition rates that would corroborate the inferred very small  $O_3$  deposition rates by Helmig et al.  
(2007a). ~~Clifton et al. (2020b) summarized that accurate process-based modelling of  $O_3$  deposition to snow requires better  
understanding of the underlying processes and dependencies.~~ An eddy-covariance system has been set up as part of the MO-

SAiC campaign and will provide year-round O<sub>3</sub> deposition fluxes to several land surface types such as open ocean and sea ice  
515 with fluctuating snow cover. These measurements will further enhance our understanding of O<sub>3</sub> deposition in shallow ABLs at  
high latitudes ([Clifton et al., 2020a](#)) and the further role in regional atmospheric chemistry.

In this study we used the COAREG transfer algorithm version 3.6 which is extended with a two-layer scheme for surface  
resistance compared to the previous versions (Fairall et al., 2007, 2011) and similar to ~~the work by Luhar et al. (2018). Oceanic  
iodide (I<sub>aq</sub>) is generally deemed to be the most significant reactant for O<sub>3</sub> in ocean water (Chang et al., 2004). Similar to  
520 Pound et al. (2019) we have used the global I<sub>aq</sub> distribution by Sherwen et al. (2019) on a spatial resolution of 0.125° × 0.125°.  
This distribution replaces the previously applied iodide estimations only using SST (Chance et al., 2014; MacDonald et al., 2014)  
- Using the Sherwen et al. (2019) distribution for August/September we found relatively high I<sub>aq</sub> concentrations ranging from  
30 to 130 nM whereas the MacDonald et al. (2014) estimation would imply I<sub>aq</sub> concentrations ranging from 5 to 50 nM. This  
implies that in the WRF setup, using the Sherwen et al. (2019) I<sub>aq</sub> distribution, the cold Arctic ocean is still quite effective  
525 in removing O<sub>3</sub> from the surface waters having I<sub>aq</sub> as a reactant. On the global scale, the most recent I<sub>aq</sub> climatology by  
Sherwen et al. (2019) most accurately represents the observed I<sub>aq</sub> compared to estimations only using SST (Chance et al., 2014; MacDonal  
- However, Sherwen et al. (2019) noted that the I<sub>aq</sub> estimations at high latitudes (north of ≥ 65°N) are very poorly constrained  
by the observational datasets and are therefore also an uncertainty in this study on Arctic O<sub>3</sub>. Therefore, new I<sub>aq</sub> measurements  
at high latitudes, for example those performed during the MOSAiC expedition, will be very useful to better constrain the  
530 global I<sub>aq</sub> distributions as well as mechanistic oceanic O<sub>3</sub> deposition representations. The WRF simulations in this study did  
not consider [Luhar et al. \(2018\)](#). Our WRF simulations excluded the additional role of chlorophyll, Dissolved Organic Matter  
(DOM) or other species such as DMS on chemical enhancement of O<sub>3</sub> in surface waters. Experimental studies have shown that  
DMS, chlorophyll, or other reactive organics, ~~can~~ may enhance the removal of O<sub>3</sub> at the sea surface ([Chang et al., 2004](#); [Clifford et al., 2008](#)  
[Chang et al., 2004](#); [Clifford et al., 2008](#); [Reeser et al., 2009](#); [Martino et al., 2012](#)). The global modelling study by Ganzeveld  
535 et al. (2009) included a chlorophyll-O<sub>3</sub> reactivity that increased linearly with chlorophyll concentration as a proxy for the  
role of DOM in oceanic O<sub>3</sub> deposition. ~~The addition of this reaction significantly~~ Including this reaction substantially  
enhances O<sub>3</sub> deposition to coastal waters such that actually observed O<sub>3</sub> deposition to these coastal waters is well reproduced  
(Ganzeveld et al., 2009). Other studies ~~on oceanic O<sub>3</sub> deposition~~ such as Luhar et al. (2017); Pound et al. (2019) ~~did not~~  
~~consider~~ ignored the potential role of DOM-O<sub>3</sub> chemistry in oceanic O<sub>3</sub> deposition. ~~The study by~~ Luhar et al. (2018), which  
540 did not explicitly consider coastal waters, even suggested that including such a reaction deteriorates the comparison with O<sub>3</sub>  
flux observations above open oceans. A considerable uncertainty in the DOM-O<sub>3</sub> reaction is the second-order rate coefficient  
but also the magnitude and variability in oceanic DOM concentrations (Luhar et al., 2018). To test the sensitivity of our model  
setup to other reactants in the surface water we have performed an additional sensitivity analysis including the chlorophyll-O<sub>3</sub>  
and DMS-O<sub>3</sub> reactions from Ganzeveld et al. (2009). ~~Regarding chlorophyll we have used the monthly~~ Oceanic chlorophyll  
545 concentrations have been retrieved from the 9 × 9 km resolution MODIS chlorophyll-α ~~concentrations~~ dataset available at  
[https://modis.gsfc.nasa.gov/data/dataproduct/chlor\\_a.php](https://modis.gsfc.nasa.gov/data/dataproduct/chlor_a.php) (last access: 14 Aug 2020). ~~For DMS~~ Chlorophyll-α concentrations are  
typically < 3 mg m<sup>-3</sup> for open oceans up to 25 mg m<sup>-3</sup> for coastal waters. For oceanic DMS concentrations, we use the monthly  
climatology from Lana et al. (2011). The sensitivity study with chlorophyll as extra reactant indicated a slight increase (up~~

to 5%) in deposition to coastal waters with chlorophyll concentrations up to  $25 \text{ mg m}^{-3}$ . However, the resulting effect on surface  $\text{O}_3$  concentrations was not significant due to the large fraction of oceans with very low ( $< 3 \text{ mg m}^{-3}$ ) chlorophyll- $\alpha$  concentrations. Also the reactions with oceanic DMS appear to be weak due to relatively low DMS concentrations in August/September. ~~A-These sensitivity studies indicate that  $I_{\text{aq}}$  is the main driver of chemical reactivity of  $\text{O}_3$  in the Arctic ocean in summer. However a~~ potential sensitivity of these reactants on Arctic  $\text{O}_3$  deposition could especially be expected in the spring to summer transition following from algal blooms (Stefels et al., 2007; Riedel et al., 2008). However, in springtime the removal of Arctic  $\text{O}_3$  near the surface is also largely affected by halogen chemistry (Pratt et al., 2013; Thomas et al., 2013). ~~In this season, the~~ (Pratt et al., 2013; Thomas et al., 2013; Yang et al., 2020) and which is known to explain observed surface  $\text{O}_3$  mixing ratios can drop dropping to 0 ppb (Halfacre et al., 2014). ~~It this study we have limited our analysis to a period in which~~ However, this feature is of less relevance for the presented study with the evaluation being focused on August/September and when the role of halogen chemistry is ~~not important deemed being less important~~ (Yang et al., 2020).

We nudged the WRF model to the ECMWF ERA5 reanalysis product to ensure a fair model evaluation with observations due to a better representation of the synoptic conditions. This indicated the important role of the model representation of ~~meteorolog~~meteorology, e.g. advection of polluted air and mixing/entrainment of  $\text{O}_3$  in the ABL, in representing the observed surface  $\text{O}_3$  concentrations. ~~An improvement in simulated synoptic conditions was also found when initializing and nudging the model with ECMWF ERA-Interim data (Dee et al., 2011). This indicates that both reanalysis products have a better representation of the actual synoptic conditions than the free running WRF model.~~ The model evaluation was set up at a resolution of  $30 \times 30 \text{ km}$  which is in the order of the ERA5 reanalysis data ( $0.25^\circ \times 0.25^\circ$ ) used for initial conditions, boundary conditions and nudging. ~~Nudging, but then to the NCEP-FNL reanalysis data, was also applied in a study by Marelle et al. (2017) using WRF for quasi-hemispheric simulations of aerosols and  $\text{O}_3$  in the Arctic at a resolution of  $100 \times 100 \text{ km}$ . In this study~~ Here, we opted for a  ~~$30 \times 30 \text{ km}$  setup~~ km grid spacing because we expect that the main drivers of tropospheric  $\text{O}_3$  (chemical production and destruction, stratosphere-troposphere transport, dry deposition and mixing/advection processes) can be sufficiently resolved at this ~~resolution~~ grid spacing especially over the relatively homogeneous ocean, ice and snow surfaces. However, we do realize that ~~the use of a  $30 \times 30 \text{ km}$  might have caused some issues in such a coarse grid spacing may have hampered~~ representing local air flow phenomena such as katabatic winds (Klein et al., 2001) which could explain some of the mismatch at sites like Villum (Nguyen et al., 2016). Another justification for the  ~~$30 \times 30 \text{ km}$  resolution~~ km grid spacing was to limit computational time and to have a large enough domain to cover the entire region above  $60^\circ \text{N}$  to conduct a large pan-Arctic evaluation while at the same time having all observational sites far enough from the domain boundaries to limit the effect of the imposed meteorological and chemical boundary conditions.

~~We plan to use a similar model setup, but then at a higher resolution or using a 1D-setup, to evaluate the~~ In general, the relatively scarce Arctic observations introduces constraints to modelling studies and limits the potential of these results to be extrapolated to other seasons and lower latitudes. In this case, this includes the uncertainty in the magnitude and distribution of driving factors of oceanic  $\text{O}_3$  concentration and flux measurements in and around the Arctic sea ice deposition such as  $I_{\text{aq}}$  (Sherwen et al., 2019) or DOM. New  $I_{\text{aq}}$  measurements at high latitudes, for example those performed during the year-round MOSAiC expedition. These observations will likely give insight in the role, will be very useful to better constrain the global

$\Gamma_{aq}$  distributions as well as mechanistic oceanic  $O_3$  deposition representations. Measurements of  $O_3$  deposition to sea-ice and concentrations and deposition fluxes to the Arctic ocean during different seasons (e.g. wintertime with no photo-chemistry or springtime with active halogen chemistry) and for a wide range of meteorological conditions. Furthermore, this local flux and concentration evaluation can be extended to species such as DMS which is now also included in the COAREG version that is coupled to WRF. However, this lacks a combined seawater and atmospheric concentration and flux dataset to conduct a local validation or a similar pan-Arctic distributed surface network such as presented here for  $O_3$  to perform an indirect regional assessment. can assist to better constrain these modelling setups in terms of magnitude and temporal variability and potentially indicate of the sensitivity to other environmental factors such as wind speed in waters with low reactivity. Furthermore, including the role of halogen chemistry (Pratt et al., 2013; Thompson et al., 2017) might give an indication of the combined role of halogens and oceanic deposition in removing  $O_3$  and explaining the magnitude and short- but also long-term variability of  $O_3$  concentrations in the High Arctic.

## 595 5 Conclusions

The mesoscale meteorology-chemistry model Polar-WRF-Chem was coupled to the Coupled Ocean-Atmosphere Response Experiment Gas transfer algorithm (COAREG) to allow for a mechanistic representation of ocean-atmosphere exchange of trace gases. Regarding the deposition of ozone ( $O_3$ ) to ocean waters, this mechanistic representation includes the  $O_3$ . This scheme represents effects of molecular diffusion, solubility, waterside turbulent transfer and chemical enhancement of  $O_3$  uptake through its reactions with dissolved iodide. The new mechanistic representation GOAREG scheme replaces the constant surface uptake resistance approach often applied in ACTMs. Furthermore, we have increased the modelled  $O_3$  surface uptake resistance to snow and ice. In total, three simulations were performed: 1) default WRF setup (DEFAULT), 2) nudged to ERA5 synoptic conditions (NUDGED) and 3) with adjustments to  $O_3$  surface uptake resistance as described above (COAREG). Furthermore, the CAMS global reanalysis data product has also been included in the comparison to illustrate some limitations in the Arctic presented evaluation on High Arctic surface  $O_3$ . This CAMS product is widely used in air quality assessments and to constrain regional scale modelling experiments. This provides additional information on the quality of the CAMS data products but also on potential issues in the representation of  $O_3$  sources and sinks, e.g., oceanic and snow/sea-ice deposition, for the High Arctic. The modelling approach was set up for an one month at the end-of-summer period in 2008 and evaluated against hourly surface  $O_3$  at 25 sites for latitudes  $> 60^\circ N$  including observations over the Arctic sea ice as part of the ASCOS campaign.

Using the mechanistic representation of ocean-atmosphere exchange,  $O_3$  deposition velocities were simulated in the order of  $0.01 \text{ cm s}^{-1}$  compared to  $\sim 0.05 \text{ cm s}^{-1}$  in the constant surface uptake resistance approach. In the COAREG run, the spatial variability ( $0.01$  to  $0.018 \text{ cm s}^{-1}$ ) in the mean  $O_3$  deposition velocities expressed the sensitivity to chemical enhancement with dissolved iodide. The temporal variability of  $O_3$  deposition velocities (up to  $\pm 20\%$  around the mean) is governed by surface wind speeds and expressed differences in waterside turbulent transport. In the constant surface uptake resistance approach, there is no spatial variability in  $O_3$  deposition velocities and the temporal variability is determined by the aerodynamic resis-

tance term that can be significant at low wind speeds. Using the mechanistic representation of ocean-atmosphere exchange reduced the total simulated O<sub>3</sub> deposition budget to water bodies by ~~~70% a factor of 3.3 compared to the default constant ocean uptake rate approach~~ and the increase in surface uptake resistance to snow and ice reduced the deposition budget by ~~~60% a factor of 2.4~~.

Despite the fact that O<sub>3</sub> deposition to oceans, snow and ice surfaces only constitutes a small term in the total O<sub>3</sub> deposition budget (~~more than~~ > 90% of the deposition is to land), we find a substantial sensitivity to the simulated surface O<sub>3</sub> mixing ratios. In the COAREG run, the simulated mean monthly surface O<sub>3</sub> mixing ratios have increased up to 50% in the typically shallow Arctic ABL above the oceans and ~~(sea-)ice-sea-ice~~ relative to the ~~DEFAULT-NUDGED~~ run. The mechanistic representation of O<sub>3</sub> deposition to oceans, but also nudging to ERA5 synoptic conditions, resulted in a substantial improved representation of surface O<sub>3</sub> observations, especially for the High Arctic sites having latitudes > 70 °N. The DEFAULT run ~~was underestimating underestimated~~ the observed surface O<sub>3</sub> mixing ratios with a bias of -7.7 ppb whereas the NUDGED and COAREG runs had a bias of -3.8 ppb and 0.3 ppb, respectively. The evaluation of the WRF runs at individual High Arctic sites showed that using the mechanistic representation of O<sub>3</sub> deposition to oceans and nudging the model to ERA5 better represents the surface O<sub>3</sub> observations in terms of magnitude as well as short-term temporal variability. ~~The evaluation of the CAMS reanalysis product also indicated limitations to represent the observed surface O<sub>3</sub> at the High Arctic in terms of magnitude and temporal variability. Similar to DEFAULT and NUDGED. Similar to the NUDGED run,~~ CAMS underestimated High Arctic observed surface O<sub>3</sub> with a bias of -5.0 ppb indicating that for this product the deposition removal mechanism to oceans and snow/ice might also be overestimated ~~and should be reconsidered~~.

This study highlights the ~~role-impact~~ of a mechanistic representation of oceanic O<sub>3</sub> deposition on Arctic surface O<sub>3</sub> concentrations at a high (hourly) temporal resolution. It ~~mostly~~ corroborates the findings of global scale studies (~~e.g. Ganzeveld et al., 2009; Luhar et al.~~) and recommends that the representation of O<sub>3</sub> deposition to oceans and snow/ice in global and regional scale ACTMs should be revised. This revision is needed not only to better quantify the O<sub>3</sub> budget at the global scale, but also to better represent the observed magnitude and short-term temporal variability of surface O<sub>3</sub> at the regional scale. ~~In addition, explicit consideration of the mechanisms involved in O<sub>3</sub> removal by the oceans (and sea-ice/snow pack) are essential to also evaluate the role of potentially important feedback mechanisms and future trends in- and the role of O<sub>3</sub> in Arctic climate change as a function of declining sea ice cover, increasing emissions and changes in oceanic biogeochemical conditions.~~ On the regional scale, this study also has implications ~~on the fate of the Arctic O<sub>3</sub> budget for methods to quantify future trends in Arctic tropospheric O<sub>3</sub>,~~ Arctic air pollution and climate in a period of declining sea ice and increasing local emissions of precursors. ~~Furthermore, this study also serves as a preparatory study for an extensive evaluation of the upcoming year-round Arctic O<sub>3</sub>, and other climate active trace gases, concentration and deposition flux measurements as part of the MOSAiC campaign.~~

*Code availability.* The COAREG algorithm is available at [ftp://ftp1.esrl.noaa.gov/BLO/Air-Sea/bulkalg/cor3\\_6/gasflux36/](ftp://ftp1.esrl.noaa.gov/BLO/Air-Sea/bulkalg/cor3_6/gasflux36/), last access: 10 September 2020. ## Appendix B: Formulation of the air- and waterside resistance terms

660 The exchange velocity, in this case deposition, of ozone ( $V_{d,O_3}$ ) [ $m\ s^{-1}$ ] is calculated from the waterside resistance ( $r_w$ ) [ $s\ m^{-1}$ ] and air side resistance terms ( $r_a + r_b$ ) [ $s\ m^{-1}$ ] as follows:

$$V_{d,O_3} = \frac{1}{\alpha r_w + r_a + r_b}. \quad (B1)$$

Here,  $\alpha$  [-] is the dimensionless solubility of  $O_3$  in sea water calculated from SST [K] following Morris (1988) as

$$\alpha = 10^{-0.25 - 0.013(SST - 273.16)} \quad (B2)$$

and the waterside resistance term ( $r_w$ ) is calculated as

$$665\ r_w = \sqrt{a * D} \frac{\Psi K_1(\xi_\delta) \cosh \lambda + K_0(\xi_\delta) \sinh \lambda}{\Psi K_1(\xi_\delta) \sinh \lambda + K_0(\xi_\delta) \cosh \lambda}. \quad (B3)$$

Here,  $a$  [ $s^{-1}$ ] is the chemical reactivity of  $O_3$  with  $\Gamma_{aq}$  calculated with the second order rate coefficient [ $M^{-1}\ s^{-1}$ ] from Magi et al. (1997) and the  $\Gamma_{aq}$  concentrations [M] from Sherwen et al. (2019):

$$a = k \cdot [\Gamma_{aq}] = \exp\left(\frac{-8772.2}{SST} + 51.5\right) \cdot [\Gamma_{aq}]. \quad (B4)$$

670 In Eq. B3,  $D$  [ $m^2\ s^{-1}$ ] is the molecular diffusivity of  $O_3$  in ocean water and is calculated from the kinematic viscosity  $\nu$  [ $m^2\ s^{-1}$ ] and the waterside Schmidt number ( $S_{cw}$ ) [-] as

$$D = \frac{\nu}{S_{cw}} = \frac{\mu}{\rho} / [\sqrt{44/48} \cdot \exp(-0.055 \cdot SST + 22.63)] \quad (B5)$$

where  $\mu$  [ $kg\ m^{-1}\ s^{-1}$ ] is the dynamic viscosity of seawater and  $\rho$  [ $kg\ m^{-3}$ ] is the density of seawater.

Finally, the air side resistance terms ( $r_a + r_b$ ) [ $s\ m^{-1}$ ] of the deposition velocity in Eq. B1 are calculated as

$$r_a + r_b = [C_d^{-1/2} + 13.3 S_c^{1/2} - 5 + \frac{\log(S_c)}{2\kappa}] / u_{*,a} \quad (B6)$$

675 where  $C_d$  [-] is the momentum drag coefficient,  $S_{ca}$  [-] is the Schmidt number for ozone in the atmosphere,  $\kappa$  is the Von Karman constant (0.4) and  $u_{*,a}$  [ $m\ s^{-1}$ ] is the friction velocity in the atmosphere. The  $r_a + r_b$  term is typically in the order of  $100\ s\ m^{-1}$  (Fairall et al., 2011).

680 Compared to COAREG version 3.1 (Fairall et al., 2007, 2011), COAREGv3.6 is extended with a two-layer scheme based on Luhar et al. (2018). This extension is included in the second term of the waterside resistance term (Eq. B3). Here,  $\Psi = \sqrt{1 + (\kappa u_{*,w} \delta_m / D)}$ ,  $\xi_\delta = \sqrt{2ab(\delta_m + bD/2)}$ , and  $\lambda = \delta_m \sqrt{a/D}$  with  $b = 2/(\kappa u_{*,w})$ . This part of the equation is a function of the chemical reactivity  $a$  [ $s^{-1}$ ] (Eq. B4), the waterside friction velocity  $u_{*,w}$  [ $m\ s^{-1}$ ], the molecular diffusivity of  $O_3$  in ocean water (Eq. B5) and  $\delta_m$  [m] representing the depth of the interface between the top water layer and the underlying turbulent layer. In this study we have applied  $\delta_m = c_0 \sqrt{D/a}$  with  $c_0 = 0.4$  based on Luhar et al. (2018).  $K_0(\xi_\delta)$  and  $K_1(\xi_\delta)$  are the modified Bessel

685 functions of the second kind of order 0 and 1, respectively. For more information on the derivation of the formulas please visit Fairall et al. (2007, 2011); Luhar et al. (2018).

690 Figure B1 shows the sensitivity of the COAREG routine coupled to WRF to the environmental factors wind speed, SST and Iodide concentration. The sensitivity to wind speeds (Fig. B1a) expresses the role of waterside turbulent transport and aerodynamic resistance. For low wind speeds waterside turbulent transport is limited and therefore limits the exchange of  $O_3$  from the atmosphere to the ocean. At high wind speeds, the dry deposition of  $O_3$  is limited by chemical reactivity of  $O_3$  with  $\Gamma_{aq}$  at typical Arctic SSTs of  $5^\circ\text{C}$  and  $\Gamma_{aq}$  concentrations of  $60\text{ nM}$  (see also Fig. C1). At very low wind speeds ( $< 3\text{ m s}^{-1}$ ) the aerodynamic resistance poses an extra restriction on the ocean-atmosphere exchange of  $O_3$ . The sensitivity to SST (Fig. B1b) mostly represents the role of solubility (Eq. B2) with warmer waters having a lower solubility. In contrast to Luhar et al. (2018), the SST is not used to calculate the  $\Gamma_{aq}$  concentrations and does therefore not show a positive correlation. The sensitivity to  $\Gamma_{aq}$  (Fig. B1c) represents the role of chemical enhancement which is stronger than the generally compensating effect of solubility in warmer waters for typical Arctic conditions.

**Figure B1.** Sensitivity of the ozone dry deposition velocity from COAREG to the environmental factors 10-meter wind speed [ $\text{m s}^{-1}$ ] (a), sea surface temperature [ $^\circ\text{C}$ ] (b) and sea surface Iodide concentration [ $\text{nM}$ ] (c) using typical values of 10-meter wind speed, sea surface temperature and Iodide concentration of  $5\text{ m s}^{-1}$ ,  $5^\circ\text{C}$  and  $60\text{ nM}$  respectively. Note that the sensitivity to sea surface temperature does not include effects of increasing reactivity but mostly represents the effect of reduced solubility (Eq. B2).

695

Appendix C: Spatial distribution of oceanic Iodide

Figure C1. Spatial distribution of Sherwen et al. (2019) oceanic Iodide concentrations [nM] at the start of the simulation.

## Appendix D: Surface ozone measurement sites.

**Table D1.** Surface ozone measurement sites subdivided in the 'High Arctic', 'Remote' and 'Terrestrial' site selections.

Name	Abbreviation	Group	Latitude [°N]	Longitude [°E]
