## 28 Abstract

29 Biomass burning (BB) is a significant source for dicarboxylic acids (diacids) and  
30 related compounds that play important roles in atmospheric chemistry and climate  
31 change. In this study, a combustion chamber and oxidation flow reactor were used to  
32 generate fresh and aged aerosols from burned rice, maize, and wheat straw to  
33 investigate atmospheric aging and the stable carbon isotopic ( $\delta^{13}\text{C}$ ) composition of  
34 these emissions. Succinic acid ( $\text{C}_4$ ) was the most abundant species in fresh samples;  
35 while, oxalic acid ( $\text{C}_2$ ) became dominant after atmospheric aging. Of all diacids,  $\text{C}_2$   
36 had the highest aged to fresh emission ratios (A/F) of 50.8 to 64.5, suggesting that  $\text{C}_2$   
37 is largely produced through secondary photochemical processes. Compared with fresh  
38 samples, the emission factors of ketocarboxylic acids and  $\alpha$ -dicarbonyls increased  
39 after 2-day but decreased after 7-day aging, indicating short residence time and further  
40 atmospheric degradation from 2- to 7-days. The  $\delta^{13}\text{C}$  values of  $\text{C}_2$   $\delta^{13}\text{C}$  values for  
41 aged biomass samples were higher than those of urban aerosols but lower than marine  
42 or mountain aerosols, and the  $\delta^{13}\text{C}$  values of  $\text{C}_2$   $\delta^{13}\text{C}$  became isotopically heavier  
43 during aging. Relationships between the reduction in volatile organic compounds  
44 (VOCs), such as toluene, benzene, and isoprene, and increase in diacidsdicarboxylic  
45 acids after 2-day aging indicate that these VOCsvolatile organic compounds led to the  
46 formation of diacidsdicarboxylic acids. However, no significant correlation was found  
47 between decreases in VOCs and increases in 7-day aged diacids. In addition, the A/F  
48 of  $\text{C}_2$  was 50.8 at 2 days and 64.5 at 7 days, indicating that the conversion of VOCs to  
49  $\text{C}_2$  was almost completed within 2 days. For the longer aging times, the particulate  
50 phase compounds may undergo further degradation in the oxidation processes.

52 isotope, VOCs

## 53 1. Introduction

54 Dicarboxylic acids (diacids), ketocarboxylic acids and  $\alpha$ -dicarbonyls are  
55 common components of the atmospheric organic aerosol, accounting for 1–3% of the  
56 total organic carbon in urban areas and >10% of the carbon mass in remote regions  
57 (Kawamura and Usukura, 1993; Kawamura and Sakaguchi, 1999; Kerminen et al.,  
58 2000; Zhao et al., 2018). Due to their high water-solubility and other physicochemical  
59 properties, diacids affect the hygroscopic growth of particulate matter (PM), and these  
60 compounds are involved in the activation of cloud condensation nuclei and formation  
61 of ice nuclei (Kawamura and Bikkina, 2016). Diacids and related compounds have  
62 been found in a wide variety of environments including urban settings (Ho et al., 2006;  
63 Kawamura and Ikushima, 1993; Meng et al., 2020; Sorathia et al., 2018; Wang et al.,  
64 2002, 2006, 2012), mountains ranges (Kawamura et al., 2013; Kunwar et al., 2019),  
65 and remote marine atmospheres (Hoque et al., 2020; Kawamura and Usukura, 1993).  
66 They also have been reported in both the Arctic and Antarctic aerosols (Kawamura et  
67 al., 1996a, b; Narukawa et al., 2002, 2003) as well as polar ice cores (Legrand and De  
68 Angelis, 1996; Kawamura et al., 2001). Various studies have assessed the molecular  
69 distributions, temporal variability, and sources of diacids in different air-sheds.

70 There are both primary and secondary sources for ~~diacids~~dicarboxylic acids  
71 (Mkoma and Kawamura, 2013). Primary sources include emissions from fossil fuel  
72 combustion (Kawamura and Kaplan, 1987; Rogge et al., 1993), cigarette burning  
73 (Rogge et al., 1994), cooking (Rogge et al., 1991), and biomass burning (BB)  
74 (Narukawa et al., 1999; Schauer et al., 2001). Of these, BB was found to be an  
75 important source of ~~diacids~~dicarboxylic acids and related compounds over regional  
76 and global scales (Kundu et al., 2010). Emissions from BB not only compose a major  
77 source of primary particles but also introduce aerosol precursors to the atmosphere  
78 (Akagi et al., 2011; Gilman et al., 2015; Reid et al., 2005). Secondary sources include  
79 particles produced by chemical/photochemical oxidation reactions of volatile organic  
80 compounds (VOCs), especially those emitted from primary sources (Lim et al., 2013;  
81 Carlton et al., 2006, 2007).

82 Being one of the major contributors to the global budget of aerosols, BB  
83 emissions are of particular concern because they impact air quality, visibility, climate,  
84 and human health (Hodshire et al., 2019). As the largest developing country and one  
85 that burns large quantities of biomass, China has long suffered from severe air  
86 pollution from BB (Chen et al., 2016; Fullerton et al., 2008). Domestic crop residues  
87 (eg. rice, maize, and wheat straw) and firewood are the most significant energy  
88 sources in most rural areas, and these are commonly used for cooking and heating (Li  
89 et al., 2021; Tao et al., 2018).

90 Diacids, ketocarboxylic acids and  $\alpha$ -dicarbonyls are products of BB (Agarwal et  
91 al., 2010). Although these acids have been measured in ambient air in some areas  
92 dominated by BB sources (FaLkovich et al., 2005; Kundu et al., 2010; Kawamura et  
93 al., 2013), there have been few BB sources emission (e.g., chamber) measurements. It  
94 was reported that BB smokes was found to contain large amounts of gaseous  
95 pollutants, such as VOCs, nitrogen oxides (NO<sub>x</sub>), sulfur dioxide (SO<sub>2</sub>), and ammonia  
96 (NH<sub>3</sub>) (Akagi et al., 2011; Andreae and Merlet, 2001). Gas-phase compounds,  
97 especially VOCs, can be partition to the particle phase through nucleation,  
98 condensation, and heterogeneous chemical reactions, creating secondary organic  
99 aerosol (SOA) and adding to aerosol mass (Hodshire et al., 2019; Lim et al., 2019).  
100 Oxalic acid (C<sub>2</sub>), the most abundant species of diacids (Kawamura and Sakaguchi,  
101 1999) and is formed by various VOCs in cloud droplets through photochemical  
102 oxidation and liquid phase reactions. It is of interest to quantify emission factors (EFs)  
103 of diacids and related compounds during the combustion of different biomass fuels in  
104 the laboratory. Kalogridis et al. (2018) performed small-scale fire experiments using  
105 the Large Aerosol Chamber (LAC, 1800 m<sup>3</sup>) with a focus on BB from Siberian boreal  
106 coniferous forests, and presented experimental data on EFs of diacids. However, this  
107 study only focused on the EFs of diacids of fresh pollutants that directly emitted from  
108 BB, so it is necessary to further investigation of molecular composition of aged BB  
109 aerosols. Although high concentrations of diacids have been detected in biomass  
110 combustion (FaLkovich et al., 2005; Kundu et al., 2010), it is still unclear on the  
111 distribution of diacids directly emitted by BB (Jaffrezo et al., 1998) or compared to

112 ~~those formed secondarily from precursors (Allen et al., 2004).~~ In addition, limited  
113 data are available on the specific ~~diacidsdicarboxylic acids~~ emitted from burning of  
114 agricultural residues. Therefore, it is important to investigate the molecular  
115 composition of ~~diacids dicarboxylic acids~~ in both fresh and aged BB aerosols to  
116 advance current understanding of the potential environmental and climatic effects.

117 In this study, rice, maize, and wheat straw were selected for laboratory  
118 simulations of fresh and aged BB aerosols. The study was conducted with the use of a  
119 combustion chamber and oxidation flow reactor (OFR). Fresh and aged BB aerosols  
120 were chemically analyzed for molecular characteristics and the stable carbon isotopic  
121 composition ( $\delta^{13}\text{C}$ ) of selected ~~diacidsdicarboxylic acids~~, ketocarboxylic acids,  
122  $\alpha$ -dicarbonyls, and benzoic. The objectives of this study were to (1) investigate the  
123 emissions of ~~dicarboxylic acidsdiacids~~, ketocarboxylic acids and  $\alpha$ -dicarbonyls from  
124 crop residue burning; (2) evaluate the effects of atmospheric aging processes on  
125 ~~dicarboxylic acidsdiacids~~ and related compounds; and (3) investigate ~~reactions~~  
126 ~~relationship between~~ of ~~volatile organic carbon compounds (VOCs)~~ with ~~oxalic~~  
127 ~~acid~~ $\text{C}_2$  and intermediates that form in the aging process to explore potential formation  
128 mechanisms of selected organic acids.

## 129 2. Methods

### 130 2.1. Preparation and collection of fresh and aged BB aerosols

131 The experimental setup is illustrated in supplementary Fig. S1. Detailed  
132 procedures for sample preparation and collection may be found in previous studies (Li  
133 et al., 2020, 2021; Niu et al., 2020). Briefly, ~~Fresh-fresh~~ smoke was generated by  
134 burning dry biomass fuels (i.e., rice, maize, and wheat straw) in an ~~~8 m<sup>3</sup>~~ combustion  
135 chamber (~~Tian et al., 2015~~), and the smoke was then passed through a Potential  
136 Aerosol Mass-Oxidation Flow Reaction (PAM-OFR) (Aerodyne Research, LLC,  
137 Billerica, MA, USA) to simulate aging processes ~~in timescale of hours to days. The~~  
138 biomass combustion chamber with a volume of ~~~8 m<sup>3</sup> (1.8m (W) × 1.8m (L) × 2.2m~~  
139 (H)), which was made of 3 mm thick aluminum to withstand high-temperature heating.  
140 The combustion chamber was equipped with a thermoanemometer, an air purification

141 system, a heated sampling line, a dilution sampler, and so on. More detailed  
142 information about the design and evaluation of combustion chamber were described in  
143 Tian et al. (2015). ~~-(Cao et al., 2020). The experimental setup is illustrated in~~  
144 ~~supplementary Fig. S1. Detailed procedures for sample preparation and collection~~  
145 ~~may be found in previous studies (Li et al., 2020, 2021; Niu et al., 2020). The~~  
146 ~~PAM-OFR can be used to simulate an environment with extremely high oxidant~~  
147 ~~concentrations with short residence times (Kang et al., 2007).~~

148 In order to get sufficient aerosols samples for measurements of chemical  
149 composition, around 1 kg biomass fuels were burned inside the chamber in 10 burning  
150 cycles. The entire burning cycle, including ignition, flaming, smoldering, and  
151 extinction, intends to simulate real-world source characterization, without the use of  
152 combustor or heat preservation. Each burning cycle, containing ~100 g biomass fuels,  
153 lasts around 12~18 min. The fresh smoke was diluted by 4.6 times using clean air  
154 controlled by the flow balance. For each test, ~100 g of the biomass fuel was burned  
155 on a combustion platform inside the combustion chamber. Each sampling period  
156 lasted 120–180 min, during which an equal amount of fuel was added to the platform  
157 10 times at regular intervals. The entire burning cycle, including ignition, flaming,  
158 smoldering, and extinction, intends to simulate real world source characterization  
159 without the use of combustor or heat preservation. Smoldering was the major driver of  
160 the combustion process. A portion of the diluted smoke by dilution sampler (Model  
161 18, Baldwin Environmental Inc., Reno, NV, USA) was drawn through a quartz fiber  
162 filter (47 mm diameter, Whatman QM/A, Maidstone, UK) at 5 L min<sup>-1</sup> using a  
163 mini-Vol PM<sub>2.5</sub> sampler (Airmetrics, OR, USA) to capture fresh emission.

164 The PAM-OFR can be used to simulate an environment with extremely high  
165 oxidant concentrations with short residence times (Kang et al., 2007). ~~A portion of the~~  
166 ~~diluted smoke was drawn through a quartz fiber filter (47 mm diameter, Whatman~~  
167 ~~QM/A, Maidstone, UK) at 5 L min<sup>-1</sup> using a mini-Vol PM<sub>2.5</sub> sampler (Airmetrics, OR,~~  
168 ~~USA) to capture fresh emission, and a~~ Another portion of the exhaust (~9 L min<sup>-1</sup>)  
169 was directed through a drawn into a 19-L cylinder PAM-OFR (with a diameter of 20  
170 cm and length of 60 cm) to simulate atmospheric aging. Residence time of PAM-OFR

171 is estimated to be  $90 \pm 1$  s at flow rate of  $9 \text{ L min}^{-1}$  (Li et al., 2021). The aging times  
172 are selected to represent lifetimes of regional air pollutants prior to arrival at a  
173 receptor (Chow et al., 2019). Three oxidants ( $\text{O}_3$ ,  $\bullet\text{OH}$ , and  $\bullet\text{HO}_2$ ) were generated in  
174 the PAM chamber using irradiation from ultraviolet (UV) lamps. The OH exposure  
175 values ( $\text{OH}_{\text{exp}}$ ) can be calculated by the concentration of  $\text{SO}_2$  and CO at the OFR inlet  
176 and outlet in a laboratory setting. Relative humidity (RH) inside the OFR was varied  
177 by passing different amounts of carrier gas through the OFR humidifier (MH-110).  
178 Additional details on smoke generation condition, test study and evaluation of the  
179 PAM-OFR were described by Cao et al. (2020).

180 In this study, The-the UV lamps operated at a voltage of 2 and 3.5 V, and the OH  
181 exposure values ( $\text{OH}_{\text{exp}}$ ) in the chamber were estimated at  $2.6 \times 10^{11}$  and  $8.8 \times 10^{11}$   
182 molecules-sec/ $\text{m}^3$ , respectively. These levels corresponded to ~2 and 7 day of aging  
183 (Chow et al., 2019; Watson et al., 2019), assuming that a representative atmospheric  
184  $\bullet\text{OH}$  level of  $1.5 \times 10^6$  molecules/ $\text{m}^3$  (Mao et al., 2009). The aged aerosols were  
185 sampled by another mini-Vol  $\text{PM}_{2.5}$  sampler ( $5 \text{ L min}^{-1}$ ) following the reactions in the  
186 PAM-OFR chamber. Each test was conducted in triplicate to account for experimental  
187 errors and to provide a measure of variability, which was calculated as standard  
188 deviations. A total of 36 samples were collected and analyzed for chemical  
189 composition.

## 190 **2.2. Sample extraction, derivatization, and quantification**

191 For diacidsdicarboxylic acids, ketocarboxylic acids and  $\alpha$ -dicarbonyls analyzing,  
192 one quarter of each filter sample was extracted three times (15 min each) with purified  
193 (18.2 M $\Omega$ ) water (Milli-Q, Merch, France) and ultrasonication. The pH of the aerosol  
194 extracts was adjusted to 8.5 to 9.0 using a 0.1 M potassium hydroxide solution prior to  
195 drying that convert carboxylic acids into their salts (Bikkina et al., 2021). This drying  
196 step improves the recovery of smaller diacids, such as oxalic acid $\text{C}_2$  (Hegde and  
197 Kawamura, 2012). Water extracts were concentrated to near dryness with a rotary  
198 evaporator under vacuum and then reacted with 14%  $\text{BF}_3$ /n-butanol at 100 °C for 1 h  
199 to derivatize carboxyl groups to dibutyl esters and oxo groups to dibutoxyacetals.

200 After derivatization, n-hexane was added and washed with pure water three times

201 to remove the water-soluble inorganics such as hydrogen fluoride and boric acid. The  
202 hexane layer was concentrated to near dryness using a rotary evaporator under  
203 vacuum and a N<sub>2</sub> blow-down technique, and then the esters and acetals of target  
204 analytes were dissolved in known amounts of n-hexane. Finally, the hexane layers  
205 were concentrated to 100 μL and analyzed using a capillary gas chromatography (GC;  
206 HP 6890, Agilent Technology, Santa Clara, CA, USA) equipped with a split/splitless  
207 injector and a flame ionization detector (FID). Peak identification was performed by  
208 comparing the GC retention times with those of authentic standards and confirmed by  
209 a thermal desorption (TD) unit coupled with a gas chromatograph/mass spectrometric  
210 detector (TD-GC/MS, Models 7890A/5975C, Agilent Technology, Santa Clara, CA,  
211 USA). The detection limits for those organic compounds were 0.1 ng m<sup>-3</sup>, and the  
212 analytical errors, based on the replicate analyses, were less than 15%. Recoveries of  
213 the target compounds were 83% for ~~oxalic acid~~C<sub>2</sub> and 87% to 110% for the other  
214 species.

### 215 **2.3. Emission factor calculations**

216 Concentrations of the various species in the aged samples were affected by their  
217 initial emission, also undergo degradation and production through secondary chemical  
218 processes. Fresh and aged fuel-based ~~emission factors~~ (EF<sub>s</sub>) for each measured  
219 chemical compound were calculated by dividing its filter mass by the mass of  
220 combusted dry biomass fuel (Andreae and Merlet, 2001; Li et al., 2020; Tian et al.,  
221 2015); that is:

$$222 \quad EF_i = \frac{m_i \times v_{Stk} \times D \times t_{sample}}{Q_p \times m_{fuel}} \times DR$$

223 where EF<sub>i</sub> (mg kg<sup>-1</sup>) is the EF of chemical compound i for the specific crop; m<sub>i</sub> (mg)  
224 is the mass of chemical compound i collected on the filter; v<sub>Stk</sub> is the average stack  
225 flow velocity (m s<sup>-1</sup>) at standard conditions; D is the stack cross section (m<sup>2</sup>); t<sub>sample</sub> is  
226 the sampling duration (s); Q<sub>p</sub> is the sampling volume through the filter (m<sup>3</sup>) at  
227 standard temperature and pressure; and m<sub>fuel</sub> is the mass of burned biomass fuel (kg,  
228 dry weight).

229 The dilution ratio (DR) was determined from the CO<sub>2</sub> concentrations measured at

230 the stack, diluted stack, and background, where:

$$231 \quad DR = \frac{CO_{2,Stk} - CO_{2,Bkg}}{CO_{2,Dil} - CO_{2,Bkg}}$$

232 where  $CO_{2,Stk}$  is the  $CO_2$  concentration in the stack;  $CO_{2,Bkg}$  the background  $CO_2$   
233 concentration in the atmosphere; and  $CO_{2,Dil}$  the  $CO_2$  concentration in the diluted  
234 smoke.

#### 235 **2.4. Stable carbon isotope composition of ~~diacids~~dicarboxylic acids**

236 Stable carbon isotopic determinations ( $\delta^{13}C$ ) of ~~dicarboxylic acids~~,  
237 ketocarboxylic acids, and  $\alpha$ -dicarbonyls followed the techniques of Kawamura and  
238 Watanabe (2004). The isotope values of the derivatized samples were determined  
239 using a gas chromatography–isotope ratio mass spectrometer (GCIR-MS; Thermo  
240 Fisher, Delta V Advantage, Franklin, MA, USA). The  $\delta^{13}C$  values were then  
241 calculated for free organic acids using an isotope mass balance equation based on the  
242 measured  $\delta^{13}C$  values of derivatives and ~~the derivatizing agent~~ (BF<sub>3</sub>/n-butanol)  
243 (Kawamura and Watanabe, 2004). To ensure the analytical error of the  $\delta^{13}C$  values  
244 less than 0.2%, each aerosol sample was analyzed in triplicate, to obtain the average  
245 values.

### 246 **3. Results and Discussion**

#### 247 **3.1. Emission factors for ~~dicarboxylic acids~~diacids, ketocarboxylic acids,** 248 **$\alpha$ -dicarbonyls**

249 Fresh and aged PM<sub>2.5</sub> EFs for a homologous series of ~~dicarboxylic acids~~diacids,  
250 ketocarboxylic acids (glyoxylic acid,  $\omega C_2$  and pyruvic acid, Pyr),  $\alpha$ -dicarbonyls  
251 (glyoxal, Gly and methylglyoxal, mGly) and benzoic acid are presented in Table 1.  
252 The EFs for most fresh and aged diacids varied by severely order-of-magnitude with  
253 higher EFs after atmospheric aging. The highest fresh EF (i.e.  $EF_{fresh}$ ) was found for  
254 wheat straw ranging 44 - 122 mg kg<sup>-1</sup> for succinic acid (C<sub>4</sub>) and 67-102 mg kg<sup>-1</sup> for  
255 ~~glyoxal~~Gly, higher than those found in maize and rice. The arithmetic means and  
256 standard deviations for the  $EF_{fresh}$  of total ~~dicarboxylic acids~~diacids from burning of  
257 rice, maize, and wheat straws were  $84 \pm 36$ ,  $130 \pm 47$ , and  $307 \pm 141$  mg kg<sup>-1</sup>,

258 respectively.

259 As is shown Fig. 1, distributions of ~~diacids~~~~dicarboxylic acids~~ in fresh emissions  
260 varied by crop types and species. Of the saturated n-dicarboxylic acids, ~~succinic acid~~  
261 ~~(C<sub>4</sub>)~~ acid was the most abundant species in the maize and wheat straw with average  
262  $EF_{fresh}$  of  $22 \pm 12$  and  $83 \pm 46$  mg kg<sup>-1</sup>, respectively. Azelaic acid (C<sub>9</sub>) and C<sub>4</sub> were the  
263 most abundant species from rice burning with  $EF_{fresh}$  of  $11 \pm 2.9$  and  $10 \pm 9.0$  mg kg<sup>-1</sup>,  
264 respectively. These findings are consistent with the fresh smoke aerosols in Siberian  
265 BB plumes (Kalogridis et al., 2018), in which C<sub>4</sub> and C<sub>9</sub> were more abundant than  
266 ~~oxalic acid (C<sub>2</sub>)~~. Previous studies also showed C<sub>9</sub> to be an oxidation product of  
267 unsaturated fatty acids in biomass smoke (Kawamura and Gagosian, 1987; Kawamura  
268 et al., 2013; Agarwal et al., 2010; Cao et al., 2017). C<sub>2</sub> is the most abundant species of  
269 diacids and is one of the final products of SOA reaction chain. In the fresh BB sample,  
270 C<sub>2</sub> emissions were lower due to the short aging time.

271 Similar to the diacids, the highest  $EF_{fresh}$  for ketocarboxylic acids and  
272  $\alpha$ -dicarbonyls were also found in wheat straw samples, with  $44 \pm 31$  and  $138 \pm 91$  mg  
273 kg<sup>-1</sup>, respectively. ~~Glyoxal (Gly)~~ was the highest  $\alpha$ -dicarbonyls, with average  $EF_{fresh}$   
274 of  $27 \pm 3.9$ ,  $42 \pm 10$ , and  $84 \pm 41$  mg kg<sup>-1</sup> for rice, maize and wheat straw,  
275 respectively. This is consistent with previous studies which showed that Gly is often  
276 more abundant than ~~methylglyoxal (mGly)~~ in polluted aerosols collected from China  
277 (Pavuluri et al., 2010; Ho et al., 2007). Benzoic acid also was determined, and its  
278  $EF_{fresh}$  for rice, maize, and wheat aerosols were  $1.9 \pm 0.2$ ,  $2.5 \pm 0.4$ , and  $3.1 \pm 0.3$  mg  
279 kg<sup>-1</sup> (Table 1).

## 280 3.2. Effects of atmospheric aging processes

### 281 3.2.1 ~~Dicarboxylic acids~~ Diacids

282 The  $EF_{aged}$  of 2- and 7-day diacids were  $1650 \pm 438$  and  $1957 \pm 598$  mg/kg,  
283 respectively (Table S1); approximately 10 times greater than the  $EF_{fresh}$ . High  
284 aged/fresh (A/F) ratios implies that the bulk of the total diacids were secondarily  
285 produced through aging processes. Longer exposure time in the atmosphere increased  
286 the formation of diacids as ratios of average aged/fresh A/F increased from 9.1 (2-day)  
287 to 10.8 (7-day) (Table S1). As shown in Fig. 2, ~~oxalic acid (C<sub>2</sub>)~~ was the most

288 abundant of all measured diacids among three crops, with the highest  $EF_{aged}$  found in  
289 wheat ( $1412 \pm 328$  mg/kg) after 7-day aging. ~~These results provide further evidence~~  
290 that  $C_2$  is produced mainly through secondary photochemical processes rather than  
291 direct emissions from BB. The aged/fresh (A/F) ratios for oxalic acid increased by  
292  $\sim 27\%$  from 50.8 (2 day) to 64.5 (7 day) (Table S1). These results are further evidence  
293 that  $PM_{2.5}$  oxalic acid is largely produced by secondary photochemical processes  
294 rather than direct emissions in biomass burning. ~~This~~ ~~at is one possible~~ also is a likely  
295 reason why  $C_2$  is often the most abundant diacid in ambient samples, especially in the  
296 oceanic and other remote areas (Hoque et al., 2020; Kawamura and Usukura,  
297 1993; Kawamura and Sakaguchi, 1999; Kunwar and Kawamura, 2014; Hegde and  
298 Kawamura, 2012; Kawamura and Bikkina, 2016; Wang et al., 2012). In addition, we  
299 found that the A/F ratio of  $C_2$  after 2-day aging was 50.8, and the change from 2~ to 7  
300 day was relatively small, only increasing by 13.7 (Table S1). These results meant that  
301 2-day aging may be sufficient for most diacids formation. It can be inferred that  
302 although diacids is still generated at 7-day aging, a large number of VOCs may have  
303 been oxidized at 2-day aging and transferred to the particle phase by condensation,  
304 adsorption and other ways. Especially for maize straw, the  $EF_{aged}$  of total detected  
305 organics at 7-day aging ( $1844 \pm 344$  mg/kg) was lower than that of at 2-day aging  
306 ( $3530 \pm 626$  mg/kg), which was mainly due to predominant role of particulate diacids  
307 degradation in longer aging time. This phenomenon is consistent with the change of  
308  $EF_S$  of VOCs (precursors of  $C_2$ ) during maize straw combustion. The decreases in of  
309  $\Sigma VOC_{EF}$  after 2-day aging ( $1227$  mg/kg) were comparable with those of 7-day aging  
310 ( $884$  mg/kg) for maize straw (Niu et al., 2020). ~~Two day aging appeared to be~~  
311 sufficient for maize, with degradation after 7 day. This may partial due to the low  
312 VOCs produced in maize burn (Niu et al., 2020). The A/F ratios in Fig. 3 showed that  
313 2-day aging is sufficient for many of the diacids.

314

315 ~~As shown in Fig. 2, oxalic acid ( $C_2$ ) was the most abundant of all measured diacids~~  
316 ~~among three crops, with the highest  $EF_{aged}$  found in wheat ( $1412 \pm 328$  mg/kg) after~~  
317 ~~7-day aging. The aged/fresh (A/F) ratios for oxalic acid increased by  $\sim 27\%$  from 50.8~~

318 ~~(2-day) to 64.5 (7-day) (Table S1). These results are further evidence that PM<sub>2.5</sub>-oxalic~~  
319 ~~acid is largely produced by secondary photochemical processes rather than direct~~  
320 ~~emissions in biomass burning. This also is a likely reason why C<sub>2</sub> is often the most~~  
321 ~~abundant diacid in ambient samples, especially in the oceanic and other remote areas~~  
322 ~~(Hoque et al., 2020; Kawamura and Usukura, 1993; Kawamura and Sakaguchi,~~  
323 ~~1999; Kunwar and Kawamura, 2014; Hegde and Kawamura, 2012; Kawamura and~~  
324 ~~Dikina, 2016; Wang et al., 2012). Two-day aging appeared to be sufficient for maize,~~  
325 ~~with degradation after 7-day. This may partial due to the low VOCs produced in~~  
326 ~~maize burn (Niu et al., 2020). The A/F ratios in Fig. 3 showed that 2-day aging is~~  
327 ~~sufficient for many of the diacids.~~

328 **Succinic acid (C<sub>4</sub>)** ranked second in abundance after C<sub>2</sub>, with 7-8 folds increased  
329 in EF after 2- and 7-day aging wheat. Although malonic acid (C<sub>3</sub>) is mainly produced  
330 by the photochemical oxidation of **C<sub>4</sub>succinic acid**, it also can be formed through the  
331 incomplete combustion of fossil fuels and biomass (Kawamura and Ikushima, 1993).  
332 In the atmosphere, C<sub>4</sub> is typically more abundant than C<sub>3</sub> originated from BB,  
333 vehicular engine exhaust and biogenic emissions (Fu et al., 2013; Kawamura and  
334 Kaplan, 1987; Kundu et al., 2010). Fig. 3 shows atmospheric aging increased the  
335 abundances of C<sub>3</sub> and C<sub>4</sub> with A/F ratios increased from 16.2 to 31.1 for **C<sub>3</sub>malonic**  
336 **acid**, and from 5.7 to 8.0 in **C<sub>4</sub>succinic acid** from 2- to 7-day of aging (Table S1).  
337 These findings add to the evidence that these diacids are produced by the  
338 photo-oxidation of primary pollutants emitted from combustion process. ~~Lower EFs~~  
339 ~~and higher Higher~~ A/F ratios in aged and fresh **C<sub>3</sub>malonic** acid than those of  
340 **C<sub>4</sub>succinic acid** may be attributed to rapid ~~oxidation-formation~~ rate of C<sub>3</sub> or  
341 decarboxylation processing of C<sub>4</sub> diacid during aging (Zhao et al., 2018).

342 As mentioned above, C<sub>9</sub> (**azelic acid**) is thought to be mainly formed through the  
343 photochemical oxidation of unsaturated fatty acids emitted by plants (Kawamura and  
344 Gagosian, 1987). Average EFs in **C<sub>9</sub>azelic** acid were low, ranging from 18 ± 7.3 mg  
345 kg<sup>-1</sup> (fresh), to 51 ± 14 mg kg<sup>-1</sup> (2-day), with A/F ratios of C<sub>9</sub> of 2.8, and 2.2 for the  
346 2- and 7-day samples, respectively, suggesting that **C<sub>9</sub>azelic acid** is relatively stable  
347 with short residence time. Fig.3 shows that A/F ratios of other long-chain ~~dicarboxylic~~

348 ~~acids~~diacids and branched ~~dicarboxylic acids~~diacids did not show apparent changes  
349 between the 2- and 7-day samples, which may be due to the degradation of long-chain  
350 ~~diacids~~dicarboxylic acids (Enami et al., 2015; Legrand et al., 2007; Miyazaki et al.,  
351 2010). It is also possible that the laboratory combustion experiment did not produce  
352 adequate quantities of certain diacids. For example, glutaric acid (C<sub>5</sub>) and adipic acid  
353 (C<sub>6</sub>) are commonly formed by reactions of cycloolefins emitted from anthropogenic  
354 sources with O<sub>3</sub> (Hatakeyama et al., 1985), and phthalic acid as a product of the  
355 photochemical oxidation of aromatic hydrocarbon compounds (Kawamura and  
356 Ikushima, 1993). Additional laboratory experiments may be needed to reify different  
357 atmospheric process.

### 358 3.2.2 Ketocarboxylic acids and $\alpha$ -carbonyls

359 In contrast to the ~~dicarboxylic acids~~diacids, aging process were not apparent in  
360 ketocarboxylic acids as A/F ratios reduced by 16% from 13.8 (2-day) to 11.9 (7-day).  
361 Similar phenomenon was found for  $\alpha$ -carbonyls with A/F ratios reduced by 64% from  
362 5.4 (2-day) to 3.3 (7-day). This suggests the possibility that the degradation of these  
363 intermediates to ~~oxalic acid~~C<sub>2</sub> is faster than their formation by oxidation after 2 days  
364 of aging. Fig.3 also show apparent reduction EF of 33-42% from 2- to 7-day aging for  
365 ~~glyoxal~~ (Gly) and ~~methylglyoxal~~ (mGly) which may be due to the fact ~~that~~ both Gly  
366 and mGly initially can be oxidized to less volatile polar organic acids including  
367 ~~pyruvic acid~~ (Pyr) and ~~glyoxylic acid~~ ( $\omega$ C<sub>2</sub>) and then further oxidized to C<sub>2</sub> (Wang et  
368 al., 2012; Warneck, 2003).

### 369 3.3. Comparisons of diagnostic ratios of ~~dicarboxylic acids~~diacids in fresh and 370 aged aerosols

371 Patterns in the relative abundances of ~~dicarboxylic acids~~diacids have been used  
372 to evaluate biogenic versus anthropogenic source strengths and the photochemical  
373 processing of organic aerosols (Kawamura et al., 2012). Previous studies have shown  
374 that C<sub>4</sub> can be directly oxidized into C<sub>2</sub> or via C<sub>3</sub> into C<sub>2</sub> (Jung et al., 2010;  
375 Sorooshian et al., 2007), with C<sub>2</sub> being an end-product of the photochemical oxidation  
376 (Wang et al., 2012). The ratios of C<sub>3</sub>/C<sub>4</sub>, C<sub>2</sub>/C<sub>4</sub> and C<sub>2</sub>/total diacids can be regarded as  
377 indicators of aerosol aging (Cheng et al., 2013; Kunwar et al., 2019; Meng et al., 2018;

378 Pavuluri et al., 2010), with higher ratios indicative of more aged aerosols (Kawamura  
379 and Sakaguchi, 1999). As shown in Table 2, the ratios in this study showed a clear  
380 atmospheric aging trend from fresh to 7-day aging with ratios of 0.7 to 6.4 for  $C_2/C_4$ ,  
381 0.1 to 0.6 in  $C_2$ /total diacids and 0.2 to 0.5 in  $C_3/C_4$ , indicating obvious photochemical  
382 oxidation. ~~with photochemically oxidization rune pronounced.~~

383 Ratios of  $\omega C_2/C_2$  and Gly/mGly can also be used to evaluate the oxidation of  
384 organic aerosols (Cheng et al., 2013, 2015; Kawamura et al., 2013). In the study,  
385 apparent reduction of the  $\omega C_2/C_2$  ratios from 1.3 (fresh) to 0.2 (7-day) supports the  
386 potential oxidation pathways from precursor glyoxylic to oxalic acids. Aqueous-phase  
387 oxidation by OH is faster for Gly than for mGly, and the abundance of Gly relative to  
388 mGly is an indicator of aerosol aging (Cheng et al., 2013). The ratio of Gly/mGly in  
389 xi'an samples was lower in haze days than in clean days, and lower in summer than in  
390 winter. Similarly, the Gly/mGly ratios in the aged biomass burningBB samples were  
391 higher in the fresh  $PM_{2.5}$  samples (3.8) compared to the 2-day ~~aged~~ (2.3) and 7-day  
392 (2.0) aging, ~~indicating the degradation for Gly proceeds more rapidly than mGly, and~~  
393 ~~that is consistent with the decline Gly/mGly ratios in aged aerosols (Cheng et al.,~~  
394 ~~2013).~~

395 Ratios of  $C_3/C_4$ ,  $C_2$ /diacids,  $\omega C_2/C_2$ , and Gly/mGly are similar among studies.  
396 Except for the higher  $C_3/C_4$  ratio of 3.9 found in marine aerosols of over the pacific  
397 region (Kawamura and Sakaguchi, 1999), and lower  $C_3/C_4$  ratios in Siberian  
398 biomass burningBB emissions in a large aerosol chamber ( $<0.03$ ) (Kalogridis et al.,  
399 2018). The largest difference was found for  $C_2/C_4$ , varied from  $<1$  for fresh aerosol in  
400 Siberian biomass burningBB (Kalogridis et al., 2018), to 25.2 from forest fire in  
401 Thailand (Boreddy et al., 2020). Elevated  $C_2/C_4$  ratios exceeding 10 were found in  
402 aged ambient Xi'an, China (10.4) (Cheng et al., 2013), Mt. Hua, China (10.7) (Meng  
403 et al., 2014), marine aerosol, Pacific ocean (14.3) (Kawamura and Sakaguchi, 1999),  
404 and ambient island Okinawa, Japan (15.5) (Kunwar and Kawamura, 2014). These  
405  $C_2/C_4$  ratios are ~63% to 142% higher than these reported in this study. Overall, these  
406 comparisons show the importance of photochemical aging, however, the atmospheric  
407 oxidation evidently was more extensive in aerosols from some remote mountain and

408 marine environments.

### 409 **3.4. Stable carbon isotopes of diacids**

410 Stable carbon isotope ratios ( $\delta^{13}\text{C}$ ) can provide insights into the sources of  
411 aerosols, Pavuluri and Kawamura (2016) reported that average  $\delta^{13}\text{C}$  values for  $\text{C}_2$   
412 from biogenic aerosols (-15.8‰) were less negative—i.e., contained more  $^{13}\text{C}$  and  
413 was isotopically enriched than those from anthropogenic aerosols (-19.5‰). Data for  
414  $\delta^{13}\text{C}$  also can provide information on the processing or aging of organic aerosols  
415 because isotopic fractionation result from chemical reactions or phase transfer  
416 (Pavuluri and Kawamura, 2016; Zhang et al., 2016). Mass loading of  $\delta^{13}\text{C}$  for diacids  
417 in the fresh BB samples were too low to be detected by the GCIR-MS, but the  $\delta^{13}\text{C}$   
418 values for  $\text{C}_2$  ranged from -23.3 to -21.0 ‰ (with an average of  $-21.9 \pm 1.2$  ‰) in  
419 2-day and -19.1 to -15.5 ‰ ( $-17.3 \pm 1.7$  ‰) for 7-day aged samples (Table 3).

420 Table 3 shows that ~~the average  $\delta^{13}\text{C}$  values of  $\text{C}_2$  from~~ aged maize samples  
421 ~~reported the a heaviest  $\delta^{13}\text{C}$  signatures higher~~ than those of rice and wheat. ~~This is The~~  
422 ~~reason for the isotope difference may be that likely because~~ maize is a  $\text{C}_4$  plant,  
423 ~~whereas while~~ wheat and rice are both  $\text{C}_3$  plants. Song et al. (2018) showed that  
424  $\delta^{13}\text{C}_{\text{TC}}$  in  $\text{C}_4$  plants is isotopically heavier than in  $\text{C}_3$  plants. Moreover, the  $\delta^{13}\text{C}$  of  $\text{C}_2$   
425 is more abundant in 7- than 2-day samples (Table 3) with  $-13.1 \pm 1.6$  ‰ (2-day) and  
426  $-7.1 \pm 1.4$  ‰ (7-day) in maize;  $-26.2 \pm 1.8$  ‰ (2-day) and  $-20.8 \pm 3.3$  ‰ (7-day) in  
427 rice and  $-26.5 \pm 0.2$  ‰ (2-day) and  $-24.0 \pm 0.5$  ‰ (7-day) in wheat combustion. The  
428  $\delta^{13}\text{C}$  data for  $\text{C}_3$ ,  $\text{C}_4$  and  $\omega\text{C}_2$  (Table S2) showed similar trends, consistent with  
429 previous studies. For example, Zhao et al. (2018) found that the  $\delta^{13}\text{C}$  values of  $\text{C}_2$   
430 were related to aging. Pavuluri and Kawamura (2016) analyzed diacids,  $\omega\text{C}_2$ , and Gly  
431 for  $\delta^{13}\text{C}$  in anthropogenic and biogenic aerosol samples by UV irradiation, and  
432 reported more  $\delta^{13}\text{C}$  less negative with longer irradiation times. During atmospheric  
433 oxidation reactions, organic compounds react with OH radicals, causing the release of  
434  $\text{CO}_2$  and CO which contain relatively the lighter  $^{12}\text{C}$  isotope and thus leaving the  
435 remaining substrate enriched in  $^{13}\text{C}$  (Hoefs, 1997; Sakugawa and Kaplan, 1995).

436 A comparison of  $\delta^{13}\text{C}$  values for  $\text{C}_2$  in the aerosols from selected environments is  
437 shown in ~~Figure Fig.~~ 4. Average  $\delta^{13}\text{C}$  value ( $-21.9 \pm 1.2$  ‰) of 2-day aged biomass

438 burning of C<sub>2</sub> was comparable to those reported for urban regions, such as Beijing  
439 (-21.8 ± 2.8‰) (Zhao et al., 2018) and Liaocheng (-19.8 ± 3.1‰) (Meng et al., 2020)  
440 (Table 3). With continued aging, the C<sub>2</sub> δ<sup>13</sup>C of the 7-day samples (-17.3 ± 1.7 ‰)  
441 was more similar in samples from Mt. Tai (-16.5 ± 1.8‰) (Meng et al., 2018) and  
442 western ~~paacific-Pacific~~ and ~~southern-Southern ocean-Ocean~~ aerosol (-16.8 ± 0.8‰)  
443 (Wang and Kawamura, 2006), but it was significantly lighter than that of samples  
444 from the Korea Climate Observatory at Gosan (-13.7 ± 2.5‰), which is a mountain  
445 background site in East Asia (Zhang et al., 2016).

### 446 3.5. Relationships between ~~decreases VOCsvolatile organic carbon compounds~~ 447 and ~~increases diacidsdicarboxylic acids~~

448 During the chamber experiment (Niu et al., 2020) concerning measured the VOC  
449 compounds. Table S3 presents the correlations between decreases in VOCs and  
450 increases in ~~dicarboxylic acids~~diacids from fresh to 2-day aged BB samples.  
451 Significant (0.01 < p < 0.05) correlations (R) were observed for toluene with Gly (R =  
452 0.75), mGly (R = 0.81), Pyr (R = 0.78), ωC<sub>2</sub> (R = 0.78) and C<sub>2</sub> (R = 0.67) (Fig. 5),  
453 suggesting that toluene was converted to diacids during the aging processes. Indeed, it  
454 has been reported that the photooxidation of toluene is a potential source of secondary  
455 organic aerosol (SOA) in urban air (Sato et al., 2007), and the major chemical  
456 components of the SOA include hemiacetal, peroxy hemiacetal oligomers and  
457 ~~dicarboxylic acids~~diacids. It also can be seen that benzene had significant correlations  
458 with mGly and C<sub>2</sub> (R > 0.59 in Fig.5), implying that the oxidation of benzene led to  
459 diacid formation. Photooxidation of Gly and mGly is a major global and regional  
460 source of C<sub>2</sub> diacid, and the two formation pathways are Gly-ωC<sub>2</sub>-C<sub>2</sub> and  
461 mGly-Pyr-ωC<sub>2</sub>-C<sub>2</sub>, respectively (Yasmeen et al., 2010; Wang et al., 2012). As shown  
462 in the Fig.5, the slope (0.20~0.59) between the decrease of toluene and the increase of  
463 intermediates (Gly, mGly, Pyr and ωC<sub>2</sub>) is significantly higher than C<sub>2</sub> (0.04). Same  
464 thing with benzene, the slope between decrease of benzene and increase of mGly is  
465 0.55, while C<sub>2</sub> is only 0.05. And we can see that the slope of the correlation between  
466 the decrease of toluene and benzene and the increase of the precursor (Pyr and ωC<sub>2</sub>) is  
467 significantly higher than that of oxalic acid.

468 On the global scale isoprene is the most important precursor for C<sub>2</sub>, contributing  
469 70% to the global C<sub>2</sub>, while anthropogenic VOCs contribute 21% to C<sub>2</sub> production  
470 (Myriokefalitakis et al., 2011). Thus, it is not surprising that isoprene correlated with  
471 C<sub>2</sub> (R=0.58) (Fig.5). In addition, several alkenes and alkanes also had a significant  
472 correlation with C<sub>2</sub> (Table S3), indicating that these species may react in secondary  
473 oxidation processes to generate ~~oxalic acid~~C<sub>2</sub>. Previous studies have confirmed that  
474 ~~dicarboxylic acids~~diacids can be oxidation products of aromatic hydrocarbons (Borrás  
475 and Tortajada-Genaro, 2012), cycloolefins (Hamilton et al., 2006), and may originated  
476 from diesel vehicle exhaust (Samy and Zielinska, 2010). However, no significant  
477 correlation was found between decreases in VOCs and increases in 7-day aged  
478 ~~diacids~~dicarboxylic acids. For the longer aging times, the particulate phase  
479 compounds may be further oxidized to generate other compounds besides diacids.  
480 Such a correlation between decreases VOCs and increases diacids again suggests that  
481 2-day aging may be sufficient to oxidize VOCs to diacids.

#### 482 4. Conclusions

483 The emission factors (EFs) of dicarboxylic acids (diacids) and related  
484 compounds in experimentally produced fresh and aged biomass burning (BB) aerosols  
485 were compared. For fresh emissions, succinic acid (C<sub>4</sub>) was the most abundant diacid  
486 species followed by azelaic acid (C<sub>9</sub>). After atmospheric aging, diacids was dominated  
487 by oxalic acid (C<sub>2</sub>)~~dominated the diacids~~, with elevated EF~~emission factors~~. Ratios  
488 of aged to fresh (A/F) for C<sub>2</sub> increased from 50.8 (2-day) to 64.5 (7-day). These  
489 results suggest that the ~~dicarboxylic acids~~diacids in the atmosphere largely originated  
490 from secondary photochemical processes as opposed to primary emissions from  
491 ~~biomass burning~~BB. It is confirmed for the first time whether the contribution of BB  
492 source to diacids is formed by primary emission or secondary oxidation. In addition,  
493 by comparing the EFs and A/F ratio of 2-day and 7-day aging, it was found that 2  
494 days of aging is sufficient for many diacids. The 2-day A/F ratios 2.8 of azelaic acid  
495 (C<sub>9</sub>) degraded by 27% after 7-days, suggesting that this species is relatively stable  
496 with short residence time.

497 Decreasing trends in EFs were found for ketocarboxylic acids and  $\alpha$ -dicarbonyls,  
498 from 2-day to 7-day aging with A/F ratios reduced from 13.8 to 11.9 and from 5.4 to  
499 3.3, respectively. These results suggest that after 2-day aging, the net degradation of  
500 these intermediates was faster than their rates of formation. Compared with 2-day  
501 samples, the  $\delta^{13}\text{C}$  of  $\text{C}_2$ , malonic acid ( $\text{C}_3$ ),  $\text{C}_4$  and glyoxylic acid ( $\omega\text{C}_2$ ) in 7-day  
502 samples became more positive or isotopically heavier after the additional aging, likely  
503 due to kinetic isotope fractionation effects. Moreover, the  $\delta^{13}\text{C}$  values for the aged  
504 maize samples in both the 2- and 7-day samples were significantly more positive than  
505 those of rice and wheat. This may be due to their different plant types with maize  
506 being~~This is likely due to differences in their photosynthetic pathways as maize is a~~  
507  $\text{C}_4$  plant, while wheat and rice are both  $\text{C}_3$  plants. The correlations between volatile  
508 organic compounds (VOCs) (benzene, toluene, isoprene, etc.) and oxalic acid ( $\text{C}_2$ ) and  
509 intermediates indicated that the oxidation of VOCs led to the formation of diacids.  
510 This correlation exists only at 2-day aging, but does not exist at 7-day aging, probably  
511 because the longer the aging time, the particle phase compounds may be further  
512 oxidized to other compounds. ~~The results provide in-depth understanding of SOAs~~  
513 ~~formation in regions greatly affected by biomass burning.~~

514 Diacid are highly water-soluble in nature and thus their high abundances due to  
515 BB and intense photochemical aging would enhance the ability of aerosols to act as  
516 cloud condensation nuclei and modify the water-uptake properties of aerosol particles.  
517 Therefore, it is necessary to better understand the chemical and physical properties of  
518 the constituents of water-soluble organic smoke, as they may have a significant  
519 impact on climate forcings through indirect aerosol effects. The results provide  
520 in-depth understanding of secondary organic aerosol (SOAs) formation in regions  
521 greatly affected by BB.

## 522 **Data availability**

523 The data involved in this study will be provided when they are asked from the  
524 corresponding authors.

525 **Author contribution**

526 Junji Cao and Jianjun Li conceived and designed the study. Minxia Shen  
527 contributed to the literature search, samples and data analysis, and manuscript writing.  
528 Jianjun Li, Junji Cao, Judith C. Chow and John G. Watson contributed to manuscript  
529 revision. Kin Fai Ho, Wenting Dai, Suixin Liu, Ting Zhang, Qiyuan Wang, Jingjing  
530 Meng carried out the particulate samples and supervised the experiments. All authors  
531 commented on the manuscript and reviewed the manuscript.

532 **Declaration of Competing Interest**

533 The authors declare that they have no known competing financial interests or  
534 personal relationships that could have appeared to influence the work reported in this  
535 paper.

536 **Acknowledgments**

537 This work was jointly supported by the program from National Nature Science  
538 Foundation of China (No. 41977332), the Strategic Priority Research Program of  
539 Chinese Academy of Sciences (No. XDB40000000), the Innovation Capability  
540 Support Program of Shaanxi (No. 2020KJXX-017), and by the US National Science  
541 Foundation (AGS-1464501 and CHE 1214463). Jianjun Li also acknowledges the  
542 support of the Youth Innovation Promotion Association CAS (No. 2020407).
