### 10 **S1. Measurements of bead speeds of particles**

Renbaum-Wolff et al. (2013a) introduced the method of the bead-mobility technique to determine viscosity of aerosol particles. In this study, bead speeds were measured at different relative humidity (RH) and then the bead speeds were converted to viscosities using a calibration line (Fig. S1). The calibration line was produced by measurement of bead speeds as a function of viscosities of sucrose/H<sub>2</sub>O particles at  
15 different RH. The values were fit to a power function, *bead speeds* ( $\mu\text{m}/\text{ms}$ ) =  $a \times (\text{viscosity } (\text{Pa s}), \eta)^b$ .  $a$ ,  $b$  are the best-fit parameters, and used  $a = 1.84 \times 10^{-4}$  and  $b = -1.08$  in this study. The values agree well with the previous study of Renbaum-Wolff et al. (2013a).

20 Figure S1. A calibration line of mean bead speeds as a function of viscosities of sucrose/H<sub>2</sub>O particles at different RH. The red line indicates a best-fit line and pink envelopes indicate the 95% prediction bands of the fitting in sucrose/H<sub>2</sub>O particles. The mean bead speed error bars (on *x*-axis) represent the standard deviation from the measurements of 3-5 beads per particle at a given relative humidity.

25 Figure S2 shows the mean bead speeds at different RH of sucrose/H<sub>2</sub>O (Fig. S2a), Mg(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O and Ca(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O (Fig. S2b), and sucrose/Mg(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O and sucrose/Ca(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O (Fig. S2c). The bead speeds of the sucrose/H<sub>2</sub>O particles decreased from  $\sim 9 \times 10^{-4}$  to  $\sim 1 \times 10^{-5} \mu\text{m} \cdot \text{ms}^{-1}$  when the RH decreased from  $\sim 85$  to  $\sim 69$  % RH (Fig. S2a). In Fig. S2b, the mean bead speeds of Mg(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O decreased from  $\sim 5 \times 10^{-2}$  to  $6 \times 10^{-3} \mu\text{m} \cdot \text{ms}^{-1}$  as the RH reduced from  $\sim 66$  to  $\sim 35\%$ , and the speeds of Ca(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O  
30 decreased from  $9 \times 10^{-3}$  to  $1 \times 10^{-6} \mu\text{m} \cdot \text{ms}^{-1}$  as the RH decreased from  $\sim 62$  to  $\sim 12\%$ . The mean bead speeds of sucrose/Mg(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O particles decreased from  $\sim 6 \times 10^{-3}$  to  $\sim 1 \times 10^{-5} \mu\text{m} \cdot \text{ms}^{-1}$  at RH ranges from  $\sim 68$  to  $\sim 35\%$ , and the bead speeds of the sucrose/Ca(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O particles reduced from  $\sim 8 \times 10^{-3}$  to  $\sim 5 \times 10^{-6} \mu\text{m} \cdot \text{ms}^{-1}$  as the RH decreased from  $\sim 80$  to  $\sim 40\%$  RH (Fig. S2c). These bead speeds of the particles were converted to the viscosities using the calibration line shown in Fig. S1.

35

Figure S2. The bead speeds of each species as function of relative humidity (RH). (a) sucrose/ $\text{H}_2\text{O}$ , (b)  $\text{Mg}(\text{NO}_3)_2/\text{H}_2\text{O}$  and  $\text{Ca}(\text{NO}_3)_2/\text{H}_2\text{O}$ , and (c) sucrose/ $\text{Mg}(\text{NO}_3)_2/\text{H}_2\text{O}$  and sucrose/ $\text{Ca}(\text{NO}_3)_2/\text{H}_2\text{O}$  particles. The  $x$  error bars indicate the uncertainty in the RH measurements. The mean bead speed error bars (on  $y$ -axis) represent the standard deviation from the measurements of 3-5 beads per particle at a given RH.

## 40 S2. Poke-and-flow experiments

Figure S3 illustrates the optical images of sucrose/H<sub>2</sub>O, sucrose/Ca(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O, and sucrose/Mg(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O particles from pre-poking, poking, and post-poking. Using the ImageJ software, the area of the inner hole was calculated and the experimental flow time was determined when the area decreased to 1/4 of the initial area. Figure S3 shows the experimental flow time of the sucrose/H<sub>2</sub>O particles at 43% RH as 207 s, sucrose/Ca(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O particles at 30% RH as 39 s, and sucrose/Mg(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O particles at 17% RH as 73 s. After the determining the experimental flow time ( $\tau_{(\text{exp, flow})}$ ) of the particles, the equation from Sellier et al. (2015) was applied to calculate viscosity. The  $\tau_{(\text{exp, flow})}$  of the particles was converted to the lower limit to viscosity using the equation, *The experimental timescale (s) = 0.0032 × (Viscosity (Pa s)) + 2.1 × 10<sup>-7</sup>*. For example, Fig. S3a shows an example of the optical images of sucrose/H<sub>2</sub>O at 43% RH. The  $\tau_{(\text{exp, flow})}$  of this particle was 207 s, so that the lower limit to the dynamic viscosity was calculated as  $\sim 6 \times 10^4$  Pa s. In this study, the upper limit to viscosity is unknown from the poke-and-flow technique. Figure S4a-c shows the  $\tau_{(\text{exp, flow})}$  of sucrose/H<sub>2</sub>O, sucrose/Ca(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O, and sucrose/Mg(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O particles as function of RH.

In this work, the viscosities at RH where particles cracked were determined using the poke-and-flow technique (Renbaum-Wolff et al., 2013b; Grayson et al., 2015), based on the viscosity-value where secondary organic aerosol particles cracked from previous studies (Renbaum-Wolff et al., 2013b; Grayson et al., 2015; Song et al., 2016, 2019). Previous studies obtained the lower limit of the viscosities using a fluid simulation with the lower limit of physical parameters (density, contact angle, slip length, and surface tension) and a fixed geometry with a quarter-sphere diameter (20  $\mu\text{m}$ ) which is similar what was observed in the poke-and-flow experiment after particles cracked (Renbaum-Wolff et al., 2013b; Song et al., 2016, 2019). In this study, the lower limit of contact angles for the sucrose, Ca(NO<sub>3</sub>)<sub>2</sub> and Mg(NO<sub>3</sub>)<sub>2</sub> were measured as  $\sim 72^\circ$ ,  $\sim 93^\circ$ ,  $\sim 93^\circ$  for  $\sim 5 \mu\text{l}$  of each droplet deposited on a hydrophobic substrate. The lower limit of surface tension of sucrose, Ca(NO<sub>3</sub>)<sub>2</sub>, Mg(NO<sub>3</sub>)<sub>2</sub> are from the literature (Dutcher et al., 2010; Lee and Hildemann, 2013; Grayson et al., 2015). The lower limit of density was assumed to be the density of pure water. The lower limit of slip length was assumed to be 5 nm as described in previous work (Churaev et al., 1984; Baudry et al., 2001; Joseph and Tabeling, 2005; Renbaum-Wolff et al., 2013b; Li et al., 2014; Grayson et al., 2015). These lower limits of the contact

angle, surface tension, density, and slip length are included as the lower limits of the physical parameters that were used in previous studies employing the poke-and-flow technique (Renbaum-Wolff et al., 2013b; 70 Graysong et al., 2015; Song et al., 2016, 2019). Thus, we defined the lower limit of the viscosities as  $\sim 10^8$  Pa s when a particle cracked during poke-and-flow experiments.

Figure S3. Optical images during poke-and-flow experiments at the points of pre-poking, poking, and 75 post-poking for particles consisting of (a) sucrose/H<sub>2</sub>O, (b) sucrose/Ca(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O, and (c) sucrose/Mg(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O particles. The scale bar is 10  $\mu\text{m}$ .

Figure S4. The experimental flow time of each species as function of relative humidity (RH) from poke-and-flow experiments. (a) sucrose/ $H_2O$ , (b) sucrose/ $Mg(NO_3)_2/H_2O$ , and (c) sucrose/ $Ca(NO_3)_2/H_2O$  particles. The  $x$  error bars indicate the uncertainty in the RH measurements. The  $y$  error bars indicate a standardization of 3 - 4 of poke-and-flow experiments at a given RH.

### S3. The morphologies of the particles during dehydrate cycles

We investigated the optical morphologies of the particles upon drying from ~100 to 0 % RH using an optical microscope (Olympus BX43 with 40× objective). Figure S5 presents the optical images of sucrose/H<sub>2</sub>O, Mg(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O, Ca(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O, sucrose/Ca(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O, and sucrose/Mg(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O particles during dehydration and hydrate cycles.

90 Figure S5. Optical images of (a) sucrose/H<sub>2</sub>O, (b) Mg(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O, (c) Ca(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O, (d) sucrose/Ca(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O, (e) sucrose/Mg(NO<sub>3</sub>)<sub>2</sub>/H<sub>2</sub>O particles on drying with a rate of 0.3% - 0.5% RH min<sup>-1</sup>. The white scale bar indicates 20 μm.

#### S4. Parameterization of viscosities

95 Parametrization of the RH as a function of the viscosities of the particles investigated was obtained using a 2<sup>nd</sup> order polynomial fit in log-scale (Fig. 4). Table S1 provides the parameterization of viscosities of each system.

Table S1. Parametrization of viscosities of different particles.  $\eta$  denotes viscosity (unit: Pa s).

System	Parameterization	Relative humidity (RH) range
sucrose/H <sub>2</sub> O	$\log_{10}(\eta) = 11.9 - 0.16 \times \text{RH} + 1.2 \times 10^{-4} \times \text{RH}^2$	24% < RH < 100%
Ca(NO <sub>3</sub> ) <sub>2</sub> /H <sub>2</sub> O	$\log_{10}(\text{Viscosity } (\eta)) = 2.5 - 0.10 \times \text{RH} + 4.2 \times 10^{-4} \times \text{RH}^2$	6% < RH < 100%
Mg(NO <sub>3</sub> ) <sub>2</sub> /H <sub>2</sub> O	$\log_{10}(\text{Viscosity } (\eta)) = -1.4 - 0.02 \times \text{RH} + 1.8 \times 10^{-5} \times \text{RH}^2$	31% < RH < 100%
sucrose/Ca(NO <sub>3</sub> ) <sub>2</sub> /H <sub>2</sub> O	$\log_{10}(\text{Viscosity } (\eta)) = 10.4 - 0.23 \times \text{RH} + 9.9 \times 10^{-4} \times \text{RH}^2$	13% < RH < 100%
sucrose/Mg(NO <sub>3</sub> ) <sub>2</sub> /H <sub>2</sub> O	$\log_{10}(\text{Viscosity } (\eta)) = 9.0 - 0.23 \times \text{RH} + 1.1 \times 10^{-3} \times \text{RH}^2$	6% < RH < 100%

#### S5. AIOMFAC-VISC with ZSR mixing rule for aqueous organic–salt systems

The deployed mixing effects of organic and inorganic solutes on phase viscosity need to be considered with the AIOMFAC-VISC model. Different possible mixing models may be introduced. The approach  
105 deployed in this work is a ZSR-type mixing rule (see main text Sect. 2.4), which is briefly characterized in the following. The goal of our method is to split the system conceptually into a salt-free aqueous organic subsystem (subsystem 1) and an organic-free aqueous electrolyte subsystem (subsystem 2), such that we can compute the individual mixture viscosities ( $\eta_1, \eta_2$ ) of those subsystems with AIOMFAC-VISC at the same water activity (RH) as is computed by AIOMFAC for the whole mixed organic–inorganic system.  
110 The mixture viscosity of the full (ternary) system is then estimated using a weighted arithmetic mean of the logarithms of subsystem viscosities; formally,

$$\ln(\eta/\eta^\circ) = f_1 \ln(\eta_1/\eta^\circ) + f_2 \ln(\eta_2/\eta^\circ), \quad (\text{S1})$$

where  $f_1, f_2$  are weighting factors for the relative mass contributions from the subsystems, as described in the following, and  $\eta^\circ$  denotes unit viscosity (1 Pa s).

115 In the ternary case, we can use mass conservation and describe the total mass of the system ( $m$ ) as

$$m = m_{org} + m_{el} + m_w, \quad (\text{S2})$$

where subscripts  $org, el,$  and  $w$  denote, the organic, electrolyte (salt) and water components, respectively.

Similarly, we can define the masses of the two subsystems, e.g. for the aqueous organic subsystem,  $m_1 = m_{org,1} + m_{w,1}$ , with subscript 1 denoting the subsystem and analogously for subsystem 2. Using a ZSR-

120 type mixing rule, at any given water activity, the ternary system can be approximated as an additive combination of the two subsystems in terms of water content and organic and inorganic contributions. Here we define  $m_{org} = m_{org,1}$  and  $m_{el} = m_{el,2}$ , such that we can express the organic-to-inorganic dry mass ratio (OIR) as

$$\text{OIR} = \frac{m_{org}}{m_{el}} = \frac{m_{org,1}}{m_{el,2}} = \frac{w_{org,1} m_1}{w_{el,2} m_2}. \quad (\text{S3})$$

125 Here,  $w_{org,1}$  is the mass fraction of the organic (sucrose) in subsystem 1 (relative to that subsystem's composition) and  $w_{el,2}$  the mass fraction of the electrolyte (salt) in subsystem 2. We define the fractional contributions of masses from the two subsystems to the approximated mass of the whole system as  $f_1 = \frac{m_1}{m_1+m_2}$ , hence  $f_2 = 1 - f_1$ . Based on these definitions, it follows that

$$f_1 = \frac{\text{OIR} \times w_{el,2}}{w_{org,1} + \text{OIR} \times w_{el,2}}. \quad (\text{S4})$$

130 Using these weighting factors in Eq. (S1) allows for a predictive estimation of the mixture viscosity while ensuring that the target OIR is met. The mass fractions  $w_{org,1}$  and  $w_{el,2}$  result from the composition prediction at given water activity (equil. RH), here using the AIOMFAC model. Therefore, note that the values of the weights  $f_1, f_2$ , are not constant for a constant OIR; rather they must be computed at each water activity level.
