34 Abstract. Geostationary satellite measurements of aerosol optical depth (AOD) over East Asia from the GOCI and 35 AHI instruments can augment surface monitoring of fine particulate matter (PM2.5) air quality, but this requires 36 better understanding of the AOD-PM2.5 relationship. Here we use the GEOS-Chem chemical transport model to 37 analyze the critical variables determining the AOD-PM<sub>2.5</sub> relationship over East Asia by simulation of observations 38 from satellite, aircraft, and ground-based datasets. This includes the detailed vertical aerosol profiling over South 39 Korea from the KORUS-AQ aircraft campaign (May-June 2016) with concurrent ground-based PM<sub>2.5</sub> composition, 40 PM<sub>10</sub>, and AERONET AOD measurements. The KORUS-AQ data show that 550 nm AOD is mainly contributed by 41 sulfate-nitrate-ammonium (SNA) and organic aerosols in the planetary boundary layer (PBL), despite large dust 42 concentrations in the free troposphere, reflecting the optically effective size and high hygroscopicity of the PBL 43 aerosols. We updated SNA and organic aerosol size distributions in GEOS-Chem to represent aerosol optical 44 properties over East Asia by using in-situ measurements of particle size distributions from KORUS-AO. We find 45 that SNA and organic aerosols over East Asia have larger size (number median radius of 0.11 µm with geometric 46 standard deviation of 1.4) and 20% larger mass extinction efficiency as compared to aerosols over North America 47 (default setting in GEOS-Chem). Although GEOS-Chem is successful in reproducing the KORUS-AQ vertical 48 profiles of aerosol mass, its ability to link AOD to PM<sub>2.5</sub> is limited by under-accounting of coarse PM and by a large 49 overestimate of nighttime PM2.5 nitrate. The GOCI/AHI AOD data over East Asia in different seasons show 50 agreement with AERONET AODs and a spatial distribution consistent with surface PM2.5 network data. The AOD 51 observations over North China show a summer maximum and winter minimum, opposite in phase to surface PM<sub>2.5</sub>. 52 This is due to low PBL depths compounded by high residential coal emissions in winter, and high relative humidity 53 (RH) in summer. Seasonality of AOD and PM2.5 over South Korea is much weaker, reflecting weaker variation of

54 PBL depth and lack of residential coal emissions.

#### 55 1 Introduction

- 56 PM<sub>2.5</sub> (particulate matter with aerodynamic diameter less than 2.5 µm) in surface air is a severe public health
- 57 concern in East Asia, but surface monitoring networks are too sparse to thoroughly assess population exposure.
- 58 Satellite observations of aerosol optical depth (AOD) can provide a valuable complement (Van Donkelaar et al.,
- 59 2015). Geostationary satellite sensors, including the Geostationary Ocean Color Imager (GOCI) launched by the
- 60 Korea Aerospace Research Institute (KARI) in 2011 (Choi et al., 2016, 2018, 2019) and the Advanced Himawari
- 61 Imager (AHI) launched by the Japanese Meteorological Agency (JMA) in 2014 (Lim et al., 2018, 2021), offer the
- 62 potential for high-density mapping of PM<sub>2.5</sub> over East Asia (Chen et al., 2019; Wei et al., 2021a). However, more
- 63 confidence is needed in relating AOD to PM<sub>2.5</sub>. Here we evaluate the capability of the GEOS-Chem chemical
- 64 transport model (CTM) to simulate AOD-PM<sub>2.5</sub> relationships over East Asia, exploiting in-situ aircraft
- 65 measurements of vertical aerosol profiles and optical properties from the joint NASA-NIER Korea United States
- 66 Air Quality (KORUS-AQ) field study in May-June 2016 (Crawford et al., 2021; Peterson et al., 2019; Jordan et al.,
- 67 2020) together with GOCI/AHI geostationary satellite data and surface measurement networks. This enables us to
- 68 identify critical variables and uncertainties for inferring PM<sub>2.5</sub> from satellite AOD data.

- 69 A number of past studies have used satellite AOD data to infer surface PM<sub>2.5</sub> using physical and statistical models.
- 70 The standard geophysical approach has been to use a CTM, such as GEOS-Chem, to compute the PM<sub>2.5</sub>/AOD ratio
- 71 (Liu et al., 2004; van Donkelaar et al., 2006; van Donkelaar et al., 2015; Xu et al., 2015; Geng et al., 2017), with
- 72 recent applications correcting for CTM biases using available PM<sub>2.5</sub> surface network data (Brauer et al., 2016; Van
- 73 Donkelaar et al., 2016; van Donkelaar et al., 2019; Hammer et al., 2020). An alternative approach is to use artificial
- 74 intelligence algorithms to relate satellite AOD to PM<sub>2.5</sub> by training on the surface network data (Hu et al., 2017;
- 75 Chen et al., 2018; Xiao et al., 2018; Wei et al., 2021a; Wei et al., 2021b; Pendergrass et al., 2021), and sometimes
- 76 including CTM values as predictors (Di et al., 2019; Xue et al., 2019). Yet another approach is to assimilate the
- satellite-measured AODs in a CTM and correct in this manner the PM<sub>2.5</sub> simulation, although this requires
- attribution of model AOD errors to specific model parameters (Kumar et al., 2019; Saide et al., 2014; Sekiyama et
- al., 2010; Cheng et al., 2019). In all of these approaches, a better physical understanding of the AOD-PM<sub>2.5</sub>
- 80 relationship as simulated by CTMs can greatly enhance the capability to infer PM<sub>2.5</sub> from AOD data.
- 81 AOD measures aerosol extinction (scattering and absorption) integrated over the atmospheric column, so that its
- 82 relationship to 24-hr average surface PM<sub>2.5</sub> (the standard air quality metric) depends on the aerosol vertical
- 83 distribution and optical properties, ambient relative humidity (RH), diurnal variation of PM<sub>2.5</sub>, and contribution from
- 84 coarse particulate matter to AOD. Airborne measurements of aerosol vertical profiles (without species information)
- 85 in East Asia are limited (Zhang et al., 2006; Liu et al., 2009; Zhang et al., 2009; Sun et al., 2013; Li et al., 2017), and
- 86 speciated vertical profiles are rarer. AOD is highly sensitive to RH (Brock et al., 2016; Latimer and Martin et al.,
- 87 2019; Saide et al., 2020), but the impact from RH uncertainty on AOD simulation lacks evaluation. In addition,
- 88 because the AOD is a daytime measurement that needs to be related to 24-h average PM<sub>2.5</sub>, the diurnal variation of
- 89 PM<sub>2.5</sub> needs to be understood (Guo et al., 2017; Lennartson et al., 2018). Finally, although there are studies on the
- 90 optical depth of coarse mode desert dust (Eck et al., 2010; Ridley et al., 2016), there has been to our knowledge no
- 91 study of how coarse anthropogenic PM may contribute to the AOD measurements. Coarse anthropogenic PM
- 92 (distinct from desert dust) is known to be high over East Asia (Chen et al., 2015; Dai et al., 2018).

#### 93 2 Data and methods

#### 94 2.1 Observations

95 We use observations over China and South Korea from multiple platforms including surface sites, aircraft, and

96 satellites (Table 1 and 2). Surface data (Table 1) include PM<sub>2.5</sub> from national observation networks in China (Zhai et

- 97 al., 2019) and South Korea (Jordan et al., 2020), speciated PM<sub>2.5</sub> at 7 supersites in South Korea during KORUS-AQ
- 98 (Choi et al., 2019), and ground-based AODs from the AERONET network at 5 sites in East China and 10 sites in
- 99 South Korea (21 sites during KORUS-AQ). We use total and fine-mode AODs at 500 nm wavelength from the
- 100 AERONET Version 3; Spectral Deconvolution Algorithm (SDA) Version 4.1 Retrieval Level 2.0 database (Giles et
- al., 2019; O'Neill et al., 2003). The AERONET AODs at 500 nm are converted to 550 nm using total and fine mode
- 102 Ångström Exponents at 500 nm for consistency with the satellite AOD data.

103	Table 1. Surface site observations used in this work (2016)
-----	---

103	Variable     Number of sites					
	PM <sub>2.5</sub> in East China <sup>a</sup>	598				
	PM <sub>2.5</sub> in South Korea <sup>b</sup>	130				
	PM <sub>2.5</sub> composition in South Korea (May-June 2016) °	7				
	AERONET total and fine mode AOD in East China <sup>d</sup>	5				
	AERONET total and fine mode AOD in South Korea <sup>d</sup>	10-21 °				
104 105 106 107	<sup>a</sup> Hourly PM <sub>2.5</sub> from the China National Environmental Monitoring Centre (CNEMC; quotsoft.net/air/) in East China, including only sites with more than 90% data coverage in each month of 2016. Quality control of the CNEMC dataset is described in our previous study (Zhai et al., 2019). The PM <sub>2.5</sub> measurements are made at reference RH $\leq$ 35%.					
108 109	<sup>b</sup> Hourly PM <sub>2.5</sub> from the AirKorea network (airkorea.or.kr), with the same data selection criteria as for East China. The PM <sub>2.5</sub> measurements are made at reference RH $\leq$ 35%.					
110 111 112 113	<sup>c</sup> Major PM <sub>2.5</sub> components including sulfate, nitrate, ammonium, organic carbon, and black carbon at 7 supersites in South Korea during KORUS-AQ (May-June 2016; Choi et al., 2019). The mass concentration of organic carbon is converted to that of organic aerosol with a multiplicative factor of 1.8 based on KORUS-AQ observations (Kim et al., 2018).					
114 115 116 117	<sup>d</sup> AODs are from the AERONET Version 3 Level 2.0 all-points database (aeronet.gsfc.nasa.gov), except that AODs at the XuZhou site in East China are from the Version 3 Level 1.5 database. AOD at 500 nm (AOD <sub>500nm</sub> ) is converted to 550 nm (AOD <sub>550nm</sub> ) using Ångström Exponent at 500 nm (AE <sub>500nm</sub> ) following: $AOD_{550nm} = AOD_{500nm} (\frac{550}{500})^{-AE_{500nm}}$ .					
118	<sup>e</sup> AERONET AODs in South Korea are from 10 sites for the full year of 2016 and 21 sites during KORUS-AQ.					
119	The KORUS-AQ campaign (Table 2) includes 20 flights over the Kor	rean peninsula and the surrounding ocean from				
120	May 2 to June 10, 2016, with vertical profiling up to 8 km altitude. W	ve use the aircraft observations of remote and in				
121	situ aerosol extinction (scattering + absorption) coefficients, dry aerosol number size distributions, sub-micron non-					
122	refractory aerosol composition, bulk aerosol ionic composition, black carbon (BC), and relative humidity (RH).					
123	Geostationary satellite AOD at 550 nm are retrieved by the Yonsei A	erosol Retrieval (YAER) algorithm for the				
124	GOCI (Choi et al., 2016, 2018) and AHI (Lim et al. 2018) instruments, with GOCI covering East China and South					
125	Korea and AHI covering the broad East Asia region. AOD from GOCI and AHI have a 6 km $\times$ 6 km spatial					
126	resolution and 2.5-minute (AHI) to 1-hour (GOCI) temporal resolution for 8 hours per day (09:30 to 16:30 local					
127	time). We use the fused AOD product generated from the Yonsei GOCI and AHI AOD retrievals, each using two					
128	different surface reflectance methods (Lim et al., 2021). Fusion of this four-member ensemble is done by the					
129	maximum likelihood estimate (MLE) method, with weighting and averaging based on errors determined by					
130	comparison to AERONET AOD. The fused satellite AOD product is	shown by Lim et al. (2021) to have higher				
131	accuracy than its member products in comparison with AERONET data during the KORUS-AQ campaign. We will					
132	refer to it as the 'GEO satellite AOD' product in what follows.					

3 Table 2. KORUS-AQ aircraft observations used in this work (May-June 2016).

 (LAS) Model 3340.

<sup>e</sup> University of New Hampshire (UNH) Soluble Acidic Gases and Aerosol (SAGA) instrument (Dibb et al., 2003).

The cutoff aerodynamic diameter of the inlet is around 4 μm, corresponding to a geometric particle diameter of 2.5
 μm (McNaughton et al., 2007; McNaughton et al., 2009).

<sup>142</sup> <sup>f</sup> University of Colorado Boulder High-Resolution Time-of-Flight Aerosol Mass Spectrometer (HR-ToF-AMS;

143 DeCarlo et al., 2006; Nault et al., 2018; Guo et al., 2020).

<sup>g</sup> NOAA Humidified-Dual-Single-Particle Soot Photometer (HDSP2; Lamb et al., 2018).

<sup>145</sup> <sup>h</sup> NASA Diode Laser Hygrometer (DLH; Podolske et al., 2003).

#### 146 2.2 GEOS-Chem simulation

147 We use GEOS-Chem version 12.7.1 (DOI: 10.5281/zenodo.3676008) in a nested-grid simulation at a horizontal

148 resolution of  $0.5^{\circ} \times 0.625^{\circ}$  over East Asia (100-145 °E, 20-50 °N). GEOS-Chem simulates detailed tropospheric

149 oxidant-aerosol chemistry and is driven here by GEOS-FP assimilated meteorological data from the NASA Global

150 Modeling and Assimilation Office (GMAO). Boundary layer mixing uses the non-local scheme implemented by Lin

- 151 and McElroy (2010). Dry deposition of gases and particles follows a standard resistance-in-series scheme (Zhang et
- 152 al., 2001; Fairlie et al., 2007; Fisher et al., 2011; Jaeglé et al., 2018). Wet deposition of gases and particles includes
- 153 contributions from rainout, washout, and scavenging in convective updrafts (Liu et al., 2001; Amos et al., 2012; Q.
- 154 Wang et al., 2011; Q. Wang et al., 2014) with recent updates by Luo et al. (2019, 2020). We use pre-archived initial

- conditions from Zhai et al. (2021) and run the model from December 1, 2015 to December 31, 2016. The first monthis used for spin-up and the year 2016 is used for analysis.
- 157 GEOS-Chem has been used extensively to simulate PM<sub>2.5</sub> and its composition in East Asia (Geng et al., 2017; Li et
- 158 al., 2016; Choi et al., 2019; Jeong et al., 2008; Park et al., 2021; Zhai et al., 2021). Here we use the bulk
- representation of aerosols including sulfate (Park et al., 2004; Alexander et al., 2009), nitrate (Jaeglé et al., 2018),
- 160 primary and secondary organics (Pai et al., 2020), BC (Q. Wang et al., 2014), natural dust in four advected size
- 161 ranges (Fairlie et al., 2007), anthropogenic fine dust (Philip et al., 2017), and sea salt in two size ranges (Jaeglé et
- al., 2011). Heterogeneous sulfate formation on aqueous aerosols is represented by a simplified parameterization
- 163 scheme (Y. Wang et al., 2014), where the SO<sub>2</sub> uptake coefficient ( $\gamma$ ) linearly increases from 1 × 10<sup>-5</sup> at RH  $\leq$  50% to
- $164 \quad 2 \times 10^{-5}$  at RH = 100%. The thermodynamic equilibrium of sulfate-nitrate-ammonium (SNA) aerosols with the gas
- 165 phase is computed with ISORROPIA II (Fountoukis and Nenes, 2007; Pye et al., 2009) assuming an aqueous
- aerosol. We include reactive uptake on dust of acid gases (HNO<sub>3</sub>, SO<sub>2</sub>, and H<sub>2</sub>SO<sub>4</sub>), limited by consumption of dust
- alkalinity (Fairlie et al., 2010). The alkalinity of emitted dust is estimated by assuming 7.1% Ca<sup>2+</sup> and 1.1% Mg<sup>2+</sup> as
- alkaline cations by dust mass (Shah et al., 2020).
- 169 Monthly anthropogenic emissions are from the Multi-resolution Emission Inventory in 2016 for China (MEIC;
- 170 Zheng et al., 2018; http://meicmodel.org) and from the KORUSv5 emission inventory at base year 2015 (Woo et al.,
- 171 2020; http://aisl.konkuk.ac.kr/#/emission data/korus-aq emissions) for other Asian countries and shipping
- 172 emissions. MEIC over China applies weekly and diurnal scaling factors for all anthropogenic emissions (Zheng et
- 173 al., 2018). The KORUSv5 agricultural NH<sub>3</sub> emissions apply the diurnal scaling factors from MEIC. Natural
- 174 emissions include NO<sub>x</sub> from lightning (Murray et al., 2012) and soil (Hudman et al., 2012), MEGANv2 biogenic
- 175 volatile organic compounds (VOCs) (Guenther et al., 2012), dust (Meng et al., 2020), and sea salt (Jaeglé et al.,
- 176 2011). Open fire emissions are from the Global Fire Emissions Database version 4 (GFED4; van der Werf et al.,
- 177 2017).

#### 178 **2.3** AOD simulation

179 AOD in GEOS-Chem is diagnosed by integrating vertically the aerosol scattering and absorption coefficients 180 obtained with a standard Mie calculation applied to assumed size distributions, hygroscopicity, refractive indices, 181 and densities for individual aerosol components, and summing over all components (Martin et al., 2003). Optical 182 properties are listed in Table 3. Sulfate, nitrate, and ammonium share the same optical properties and are lumped as 183 an SNA aerosol component for the purpose of optical calculations. All aerosol components except dust are assumed 184 to follow log-normal size distributions. Dust includes 7 size bins (centered at radii of 0.15, 0.25, 0.4, 0.8, 1.5, 2.5, 185 and 4.0 µm) for optical calculations, with the smallest four bins partitioned by mass from the first advected dust bin 186 (< 2.5 µm in geometric diameter) following L. Zhang et al. (2013). Dust particles follow a gamma size distribution 187 within their optical size bins (Curci, 2012). The BC absorption enhancement from coating is as given by X. Wang et 188 al. (2014).

- 189 Our initial simulations indicated that aerosol extinction coefficients from the standard GEOS-Chem version 12.7.1
- 190 underestimated in situ measured extinction coefficients during KORUS-AQ by 20% on average (Figure S1). We
- 191 traced this problem to bias in the assumed size distributions for SNA and organic aerosol, as shown in Section 3.
- 192 Therefore, we re-computed the diagnostic AOD using updated log-normal size distributions for SNA and organic
- 193 aerosol with number median radius  $R_{N,med} = 0.11 \,\mu\text{m}$  and geometric standard deviation  $\sigma = 1.4$  based on KORUS-
- AQ observations, instead of  $R_{N,med} = 0.058 \,\mu\text{m}$  and  $\sigma = 1.6$  in the standard model version 12.7.1, which is derived
- 195 from IMPROVE network measurements of aerosol mass scattering efficiency over North America (Latimer and
- 196 Martin, 2019).

Aerosol component	$R_{N,med},  \mu \mathrm{m}$	σ	Hygroscopicity <sup>b</sup>	Refractive index	ho, g cm <sup>-3</sup>
SNA <sup>c</sup>	0.11	1.4	$\kappa = 0.61$	$1.53 - 6.0 \times 10^{-3}i$	1.7
Organic <sup>c</sup>	0.11	1.4	$\kappa = 0.1$	$1.53 - 6.0 \times 10^{-3}i$	1.3
BC	0.020	1.6	GADS	$1.75 - 4.4 \times 10^{-3}i$	1.8
Sea salt (fine)	0.085	1.5	GADS	$1.5 - 1.0 \times 10^{-3}i$	2.2
Sea salt (coarse)	0.40	1.8	GADS	$1.5 - 1.0 \times 10^{-3}i$	2.2
Dust	7 size bins	NA	$\kappa = 0^{ m d}$	$1.558 - 1.4 \times 10^{-3}i$	2.5-2.65 °

197 Table 3. Aerosol optical properties <sup>a</sup>.

<sup>a</sup> Aerosol optical properties used in this work for computing aerosol scattering and absorption coefficients. Values

are from the standard GEOS-Chem model version 12.7.1, except for the size distributions of SNA and organic

aerosol which are based on KORUS-AQ observations (see text). All aerosol components except dust have log-

201 normal dry size distributions where  $R_{N,med}$  is the number median radius and  $\sigma$  is the geometric standard deviation.

202 Refractive indices are for 550 nm wavelength.  $\rho$  is the dry aerosol mass density.

<sup>b</sup> Hygroscopic growth for SNA and organic aerosol as a function of relative humidity (RH, %) is computed from  $\kappa$ -Kohler theory as a diameter growth factor GF =  $(1 + \kappa * \text{RH}/(100\text{-RH}))^{1/3}$  (Latimer and Martin, 2019). Hygroscopic growth factors for other aerosol components are from the Global Aerosol Data Set (GADS) as tabulated in Chin et al. (2002) and Martin et al. (2003).

- 207 ° $R_{N,med}$  and σ are fit to KORUS-AQ observations as described in the text. Standard GEOS-Chem v12.7.1 assumes 208  $R_{N,med} = 0.058$  μm,  $\sigma = 1.6$  (Latimer and Martin, 2019).
- <sup>d</sup> Hygroscopic growth of dust particles is assumed negligible.
- <sup>e</sup>Sub-micron dust particles have a density of 2.5 g cm<sup>-3</sup> while coarse mode dust particles have a density of 2.65 g
- 211 cm<sup>-3</sup>. Dust size distribution is described in the text.

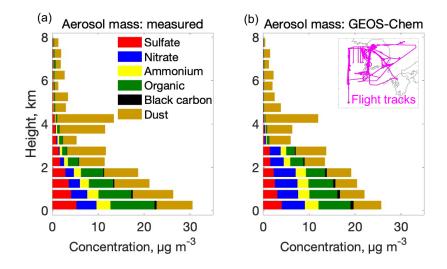

#### 212 3 Aerosol concentrations and optical properties during KORUS-AQ

- 213 Here we use the KORUS-AQ aircraft observations and their simulation with GEOS-Chem to better understand the
- 214 vertical distributions of different aerosol components contributing to AOD over South Korea. We begin with the
- 215 mean vertical profile of aerosol mass and go on to examine the aerosol optical properties. This provides the basis for
- analyzing the observed vertical profile of aerosol extinction, its simulation by GEOS-Chem, and the consistency
- 217 with GEO satellite and AERONET AOD measurements over South Korea during the KORUS-AQ period.

#### 218 **3.1** Vertical profile of aerosol mass

219 Figure 1 shows the mean aircraft vertical profiles of aerosol mass observed during KORUS-AQ and their simulation

- by GEOS-Chem. The KORUS-AQ aircraft sampled during the daytime, mainly between 9 am and 3 pm local time.
- Here and elsewhere, the model is sampled along the flight tracks and at the flight times. The observed vertical
- distribution of aerosol mass concentrations (Figure 1a) shows that 58% of column aerosol mass is below 2 km
- altitude, which we define as the average planetary boundary layer (PBL) during KORUS-AQ, and 34% is at 2-5 km
- altitude, which we define as the lower free troposphere (FT). The model has a similar vertical distribution (Figure
  1b), with 57% of aerosol mass in the PBL and 36% in the lower FT. SNA, organic, and dust each contribute about a
- third of aerosol mass in the PBL while dust dominates in the lower FT both in the observations and in the model.
- 227 The enhanced dust in the lower FT is driven by a few dust events, which the model reproduces (Figure S2). Black
- carbon and sea salt (not shown) make only minor contributions to aerosol mass. The model underestimates sulfate
- by 28% in the PBL, which leads to a 20% overestimate of nitrate, with canceling effect on the SNA mass simulation.
- 230 The GEOS-Chem simulation of organic aerosol in this work uses the simple scheme of Pai et al. (2020) and
- underestimates aircraft observations by 16% in the PBL. Over 90% of GEOS-Chem organic aerosol is secondary,
- consistent with observations (Figure S4; Nault et al., 2018; Pai et al., 2020). GEOS-Chem simulation of the
- 233 KORUS-AQ aerosol component profiles for different meteorological regimes is presented in Park et al. (2021).

- Figure 1. Vertical profiles of aerosol mass during KORUS-AQ. Panel (a) shows the mean vertical distributions of
- observed mass concentrations of major aerosol components at ambient temperature and pressure. Panel (b) is the same as
- 237 (a) but from the GEOS-Chem model sampled along the flight tracks (inset). We derive dust concentration from SAGA
- 238 Ca<sup>2+</sup> and Na<sup>+</sup> following Shah et al. (2020) by assuming that non-sea salt Ca<sup>2+</sup> accounts for 7.1% of dust mass: [dust] =
- 239 ([Ca<sup>2+</sup>] 0.0439 [Na<sup>+</sup>]/2) / 0.071 where the brackets denote mass concentration. Modeled dust is shown for particles with
- 240 geometric diameter < 2.5 μm, to be consistent with SAGA measurements (Table 2 footnote e). Measured sulfate, nitrate,
- ammonium, and organic aerosol concentrations are from the AMS instrument (values from the SAGA instrument are
- shown in Figure S4). All data are averaged over 500-m vertical bins. Here and elsewhere, we excluded pollution plumes
- 243 diagnosed by either  $NO_2$  or  $SO_2 > 10$  ppbv (3.4% of all the data).

#### 244 **3.2** Aerosol size distributions

Figure 2a shows the normalized dry aerosol number size distributions on each of the 20 flights and in 3 altitude

bands: < 1.5 km, 3-5 km, and 6-7 km (60 lines). The spread in the size distributions above 1  $\mu$ m in diameter reflects

247 dust influence. We select measurements below 1.5 km altitude when SNA + organic aerosol mass concentrations are

- 248 more than 4 times that of dust as defining the SNA + organic aerosol size distributions (green lines in Figure 2a).
- 249 Conditions dominated by SNA + organic aerosols define the lower envelopes of the ensemble of size distributions at
- 250 diameter > 1  $\mu$ m. SNA and organics were observed to have similar size distributions during KORUS-AQ (Kim et
- 251 al., 2018).
- Figure 2b converts the SNA + organic dominated number size distributions to volume size distributions. The
- 253 observed SNA + organic dominated aerosol size distribution is shifted toward larger sizes relative to the standard

254 GEOS-Chem. The secondary maximum in the coarse mode could be due to dust. We fitted the observed SNA +

organic aerosol size distributions to a lognormal distribution with volume median radius  $R_{V,med} = 0.15 \,\mu\text{m}$  and

256 geometric standard deviation  $\sigma$ = 1.4. The number median radius is derived from the volume median radius

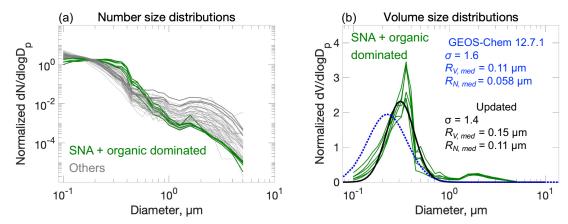

257 following Seinfeld and Pandis (2016):

$$\ln R_{N,med} = \ln R_{V,med} - 3\ln^2 \sigma \tag{1}$$

259 which yields *R<sub>N,med</sub>* = 0.11 μm. In comparison, the standard GEOS-Chem size distribution from Latimer and Martin

260 (2019) has  $R_{N,med} = 0.058 \,\mu\text{m}$  and  $\sigma = 1.6$ . We adopt the observed log-normal size distribution parameters in what

follows (Table 3).

264 Figure 2. Aerosol dry size distributions measured in the KORUS-AQ aircraft campaign. Panel (a) shows mean 265 normalized number size distributions measured on each of the 20 flights and for 3 altitude bins: < 1.5 km, 3-5 km, and 6-7 266 km (60 lines total). The SNA + organic dominated size distribution profiles are highlighted in color. Panel (b) shows 267 normalized volume size distributions for conditions dominated by SNA + organic aerosols (green lines), along with a least-268 square fit to a lognormal distribution (black line), and the standard GEOS-Chem v12.7.1 size distribution from Latimer 269 and Martin (2019) (blue dashed line). Normalization imposes an arbitrary value of unit area below each line. Lognormal 270 distribution parameters are inset in panel (b) including volume median radius ( $R_{V,med}$ ), number median radius ( $R_{N,med}$ ), 271 and geometric standard deviation ( $\sigma$ ).

#### 272 **3.3** Aerosol extinction and relation to AOD

Figure 3 shows the vertical profiles of ambient aerosol extinction coefficients and RH during KORUS-AQ. Vertical profiles of aerosol extinction were measured on the aircraft both remotely with the HSRL instrument (above and below the aircraft) and in situ with TSI-3563 nephelometers (for scattering) and PSAPs (for absorption). The two agree well, as shown in Figure 3a. They indicate that 76-90% of column aerosol extinction is in the PBL at 0-2 km altitude and 9-19% is in the lower FT at 2-5 km. Both measurements show that aerosol extinction is much more strongly weighted to the PBL than aerosol mass (Figure 1).

Also shown in Figure 3a are the contributions of individual aerosol components to the extinction profile, as

280 computed from the GEOS-Chem optical properties (Table 3) applied to the observed mass concentrations. The sum

shows a good match to the measured extinction coefficient profiles. The much larger contribution of the PBL to

282 column aerosol extinction than to column mass is because aerosol mass in the lower FT is mainly composed of dust,

- 283 whose mass extinction efficiency is much smaller than SNA and organics due to its coarse size and lack of
- hygroscopic growth (Figure S5). The mean AOD inferred from the aircraft data is 0.36 and is contributed 59% by
- 285 SNA, 27% by organic aerosol, 12% by dust, and 2% by BC. It is consistent with the mean AODs measured at
- AERONET stations in South Korea during KORUS-AQ (Figure S6).

- 287 Figure 3b shows the GEOS-Chem simulation of aerosol extinction profiles for comparison to the observations in
- Figure 3a. The model underestimates extinction coefficients by 20% below 1 km altitude, leading to a 10%
- underestimate of aircraft inferred AOD, although there is no such underestimate in aerosol mass. This is caused by a
- 290 negative RH bias in the GEOS-FP meteorological data used to drive GEOS-Chem, particularly at high RH
- 291 conditions (Figure 3c) and is corrected if we apply the observed RH rather than the GEOS-FP RH to the GEOS-
- 292 Chem aerosol mass concentrations (Figure 3d).

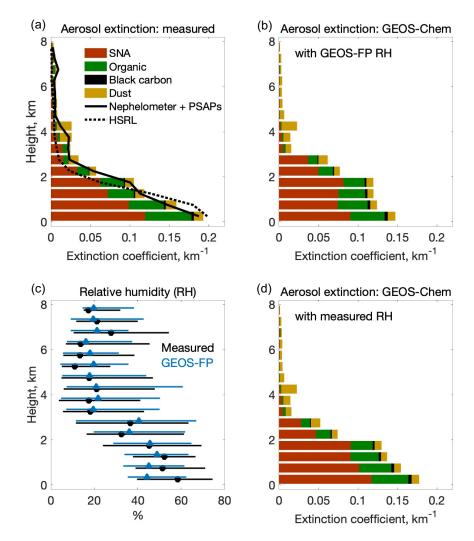

Figure 3. Vertical profiles of aerosol extinction coefficients and relative humidity (RH) during KORUS-AQ. Panel (a)

shows the mean observed vertical distributions of 550 nm extinction coefficients measured in situ (nephelometer + PSAPs;

- at ambient RH) and remotely (HSRL), along with an independent calculation (colored horizontal bars) from the
- 297 measured mass concentrations of major aerosol components, measured RH, and GEOS-Chem optical properties as given
- in Table 3. Panel (b) shows the mean aerosol extinction profile in GEOS-Chem and the contributions from the different
- 299 model components. Panel (c) is the median vertical profile of RH (horizontal bars are 25-75<sup>th</sup> percentiles) from aircraft
- 300 measurements and the GEOS-FP assimilated meteorological data used to drive GEOS-Chem. Panel (d) is the same as (b)
- 301 but calculated using measured RH.

#### 302 4 AOD and surface particulate matter over South Korea during KORUS-AQ

Our analysis of Section 3 used the KORUS-AQ aircraft data together with GEOS-Chem to attribute AOD over
 South Korea to individual aerosol components and altitudes. We now take the next step of evaluating the capability
 of GEOS-Chem to independently simulate observed AODs and surface particulate matter concentrations.

Figure 4a shows the spatial distribution of the fused geostationary satellite (GOCI/AHI) AOD (GEO satellite AOD)

during the KORUS-AQ period with AERONET total AOD added as circles. The GEO satellite AOD shows high

308 values (0.5-0.6) along the west coast of South Korea, significantly correlated with AERONET total AOD with a

309 spatial correlation coefficient (*R*) of 0.7. GEO satellite AOD is biased low at sites in the Seoul Metropolitan Area

310 (SMA) and is biased high on the Yellow Sea islands, resulting in an overall -10% bias. The low biases in the SMA

311 could be due to high-concentration aerosol pixels mis-identified as clouds and/or possible issues with the aerosol

type assumption in the aerosol retrieval, while the high biases on the Yellow Sea islands could result from

313 uncertainties in the assumption of ocean surface reflectance, as has been discussed by Choi et al. (2016, 2018) and

Lim et al. (2018, 2021). Sampling the AODs at or near the seven PM<sub>2.5</sub> supersites operating during KORUS-AQ

315 shows no significant bias (inset values in Figure 4a).

316 Figure 4b-e shows the spatial distributions of GEOS-Chem AOD, surface PM<sub>10</sub> (particulate matter with aerodynamic

317 diameter less than 10 µm), surface PM<sub>2.5</sub>, and surface coarse PM (PM<sub>10</sub> minus PM<sub>2.5</sub>; particulate matter with

318 aerodynamic diameter less than 10 µm and larger than 2.5 µm), with surface observations shown as circles and

319 median values at the measurement sites inset. GEOS-Chem reproduces the satellite AOD enhancements along the

320 west coast of South Korea but the values are lower than observed, which we attribute to unaccounted coarse PM and

321 negative RH bias as discussed below. Comparison of AERONET total and fine mode AOD shows a 13%

322 contribution of coarse particles to total AOD. Comparison of GEOS-Chem to the fine-mode AERONET AOD, as

323 shown in Figure 4b, finds a 15% underestimate that could be attributed to the low-RH bias (Figure 3c). Concurrent

324 measurements of  $PM_{10}$  and  $PM_{2.5}$  at AirKorea sites show that coarse PM (median 21  $\mu$ g m<sup>-3</sup>) accounts for 41% of

total  $PM_{10}$  (50 µg m<sup>-3</sup>), while coarse PM in GEOS-Chem is much lower (3.5 µg m<sup>-3</sup>; Figure 4e). Therefore, about

half of the GEOS-Chem underestimate of total AOD can be attributed to missing coarse PM, with the other half

327 comes from negative RH bias. Coarse PM has a concentration larger than  $10 \ \mu g \ m^{-3}$  across South Korea, with higher

328 concentration in the SMA (~ 30  $\mu$ g m<sup>-3</sup>) than in rural areas (~ 15  $\mu$ g m<sup>-3</sup>), implying an origin from both

329 anthropogenic and natural sources (Figure 4e).

330 GEOS-Chem overestimates surface PM<sub>2.5</sub> by 43% over South Korea (Figure 4d), in contrast to the simulation of

331 AERONET fine mode AOD (Figure 4b). Figure 4f-j shows the spatial distributions of major PM<sub>2.5</sub> components in

332 GEOS-Chem (background) and measurements (filled circles). GEOS-Chem is not significantly biased relative to the

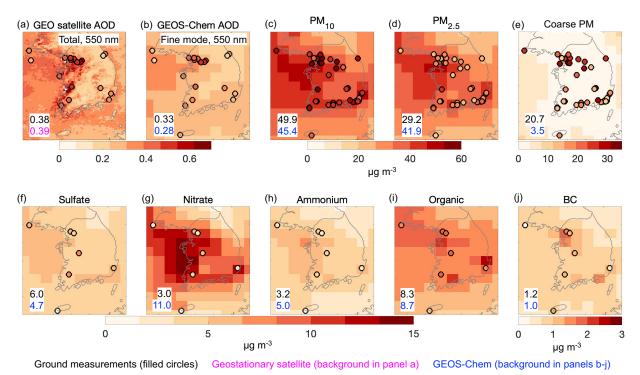

333 observations for organic aerosol and BC, and underestimates sulfate by 22%. We find that the model bias for PM<sub>2.5</sub>

is largely driven by nitrate, which is overestimated by a factor of 3 and leads to a 56% overestimate of ammonium.

335 By contrast, comparison to the KORUS-AQ data below 1-km altitude showed only a 20% overestimate of nitrate

336 (Figure 1). This is because the model bias is mainly driven by nighttime conditions (Figure 5), while aircraft

- 337 samples in the daytime during KORUS-AQ. The cause of this large model bias is analyzed by K. R. Travis et al.
- 338 (manuscript in preparation) and is attributed to nighttime nitrate chemistry and deposition in the stratified boundary
- 339 layer.

Ground measurements (niled circles) Geostationary satellite (background in panel a) GEOS-Chem (background in panels b-j)
 Figure 4. Spatial distributions of AOD and surface PM<sub>10</sub>, PM<sub>2.5</sub>, coarse PM (PM<sub>10</sub> minus PM<sub>2.5</sub>), and major PM<sub>2.5</sub>
 components over South Korea averaged during KORUS-AQ (May 9 - June 10, 2016). Panel (a) shows the fused
 geostationary (GEO) 550 nm AOD from the GOCI and AHI satellites (background) and AERONET 550 nm total AOD
 (filled circles). Panel (b) shows GEOS-Chem 550 nm AOD sampled at hourly GEO satellite AOD (GEOS-Chem clear-sky)

AOD; background) and AERONET 550 nm fine mode AOD (filled circles). Panel (c) shows surface PM<sub>10</sub> modelled by

- 346 GEOS-Chem (background) and measured at ground sites (filled circles). Panels (d-j) are the same as panel (c) but
- 347 respectively for PM<sub>2.5</sub>, coarse PM (PM<sub>10</sub> minus PM<sub>2.5</sub>), and sulfate, nitrate, ammonium, organic, and BC PM<sub>2.5</sub>
- 348 components. Values inset are median values from ground-based measurements (black) and sampled from GEO satellite
- 349 (magenta) and GEOS-Chem (blue). Measured PM<sub>10</sub>, PM<sub>2.5</sub>, and coarse PM in panels (c-e) are shown for a random
- 350 selection of 50% of AirKorea sites to visualize spatial distribution, and inset values are for the seven supersites where
- 351 PM<sub>2.5</sub> composition was measured. Median AOD values inset are sampled at or near the seven supersites to avoid biasing
- by the large number of sites in the Seoul Metropolitan Area. Modelled total PM<sub>2.5</sub> concentrations are calculated at 35%
- 353 RH (Table 3). Modelled PM<sub>10</sub> is the sum of PM<sub>2.5</sub>, coarse dust, and coarse sea salt.

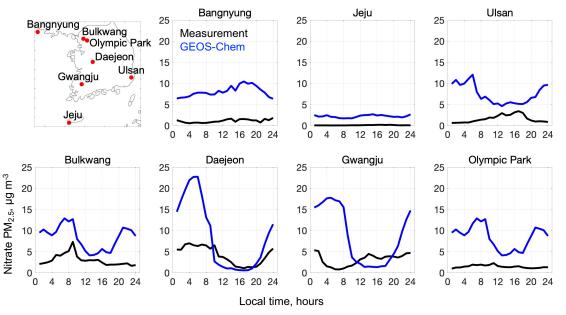

Figure 5. Median diurnal variations of PM<sub>2.5</sub> nitrate concentrations at the seven supersites (top left panel) operated in

356 South Korea during KORUS-AQ (May 9 - June 10, 2016). Values are medians binned by hour. GEOS-Chem model

357 values are sampled to coincide with the measurements.

#### 358 5 AOD and its relationship to PM<sub>2.5</sub> over East Asia

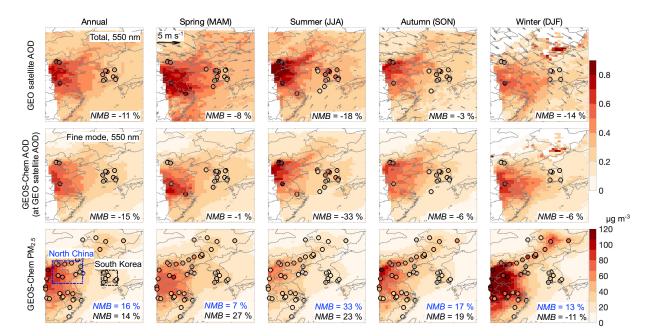

359 We build on our analysis of the KORUS-AQ period for a broader interpretation of the distribution of AOD over 360 Korea and China and its relationship to surface PM2.5, acknowledging that the conditions sampled in KORUS-AQ 361 may not be representative of other seasons or of China. Figure 6 shows the spatial distributions of 2016 annual and 362 seasonal mean geostationary (GEO) satellite AODs, the corresponding GEOS-Chem clear-sky AODs, and GEOS-363 Chem surface PM<sub>2.5</sub>. The Figure gives normalized mean biases (*NMBs*) relative to ground-based measurements from 364 AERONET and from the PM<sub>2.5</sub> surface networks (shown as circles) over the North China region (115.5-122° E, 365 34.5-40.5° N) and South Korea. The North China region is defined to overlap with the domain of the geostationary 366 satellite AOD, and to ensure consistent seasonal variations within its narrow latitude.

- 367 On an annual mean basis, AOD over North China (~0.5-0.6) is about 50% larger than over South Korea (~0.3-0.4).
- 368 AOD over South Korea shows higher values (> 0.4) in the Seoul Metropolitan Area, consistent with that during the

369 KORUS-AQ period (Figure 4a). Transport from the Asian continent is strongest in spring when the frequency of

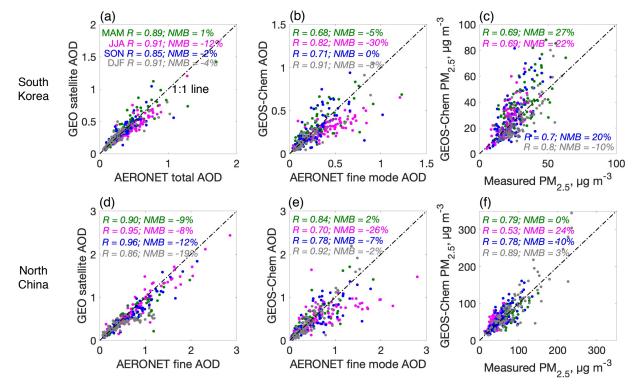

- 370 cold front passages is highest (Liu et al., 2003). AERONET total AOD in spring (0.4-0.6) is twice as large as fine-
- 371 mode AOD (0.2-0.3), reflecting a large contribution of dust. In seasons other than spring, 80-90% of AERONET
- total AOD is contributed by the fine mode. There is large seasonality in AODs over North China, and weaker
- 373 seasonality over South Korea, which will be discussed below.
- The GEOS-Chem clear-sky AODs show the same spatial and seasonal patterns as GEO satellite AODs but tend to be low in spring and summer. Comparison of the model to AERONET AODs confirms this bias and shows better

- agreement with fine-mode AOD in spring (*NMB* of -1%), implying an underestimate of coarse dust that is consistent
- 377 with our comparisons to the AirKorea network data (Figure 4e). Comparison of clear-sky and all-sky AODs in
- 378 GEOS-Chem shows no significant difference on an annual and seasonal mean basis, except for winter (Figure S7).
- 379 Winter has larger all-sky AOD than clear-sky AOD and the lowest rate of successful satellite retrievals (Figure S7),
- 380 which may be due in part to misclassification of heavy wintertime  $PM_{2.5}$  pollution as clouds (Zhang et al., 2020).
- 381 The spatial distributions of PM<sub>2.5</sub> in GEOS-Chem in different seasons match closely the observations (Figure 6,
- bottom row). We see also a close coincidence between the spatial distributions of PM<sub>2.5</sub> and AODs, both in the
- 383 observations and the model. On an annual mean basis, GEOS-Chem overestimates PM<sub>2.5</sub> by 16% in North China
- and by 14% in South Korea, even though it underestimates AERONET fine mode AODs by 15%. The overestimate
- 385 of PM<sub>2.5</sub> in South Korea is worst in spring (27%), consistent with KORUS-AQ results which we previously
- 386 attributed to excessive nighttime nitrate build-up in the model. Over North China, the overestimate of PM<sub>2.5</sub> is worst
- in summer (33%), consistent with the nitrate overestimate in summer shown in our previous study (Zhai et al.,
- 388 2021), which could also be due to model overestimate of nighttime nitrate (Miao et al., 2020).

390 Figure 6. Spatial distributions of 2016 annual and seasonal mean AOD (550 nm) and surface PM2.5. The top row shows 391 the observed GOCI/AHI geostationary satellite AOD (GEO satellite AOD) on the GEOS-Chem 0.5° × 0.625° grid with 392 superimposed 925 hPa GEOS-FP wind fields and AERONET total AODs (circles). The middle row shows clear-sky 393 GEOS-Chem AOD, with AERONET fine mode AOD added as circles. The bottom row shows GEOS-Chem surface PM<sub>2.5</sub> 394 (background) with surface network measurements (circles). AERONET AODs are shown only when more than 10 395 months of data are available for the annual mean and all 3 months data are available for each season. The PM<sub>2.5</sub> 396 observations shown are for a random selection of 7% of network sites for visual clarity. GEOS-Chem PM2.5 is calculated 397 at 35% RH (Table 3). Normalized mean biases (NMBs) inset are for the comparisons of GEO satellite and GEOS-Chem 398 values to the corresponding ground measurements.

- 400 Figure 7 shows daily correlations of the regional average series between AERONET total AOD and GEO satellite
- 401 AOD, between AERONET fine mode AOD and GEOS-Chem AOD, as well as between measured PM<sub>2.5</sub> and GEOS-
- 402 Chem PM<sub>2.5</sub>. Correlations in Figure 7 are all statistically significant with correlation coefficients (*R*) ranging from
- 403 around 0.7 to more than 0.9 and normalized mean biases (*NMB*) within  $\pm$  30%. The correlations of these three pairs
- 404 are similar over South Korea and North China, except that GEOS-Chem overestimates springtime PM<sub>2.5</sub> in South
- 405 Korea but not over North China, possibly due to a model overestimate of the long-range transport of PM<sub>2.5</sub> from
- 406 China to South Korea in spring.

407

Figure 7. Scatter plots of regional mean daily (a and d) GEO satellite AOD vs. AERONET total AOD, (b and e) GEOSChem AOD vs. AERONET fine-model AOD, and (c and f) GEOS-Chem PM<sub>2.5</sub> vs. measured PM<sub>2.5</sub> over South Korea (a-c)
and North China (d-f). Different colors represent different seasons. Values inset are correlation coefficients (*R*) and

411 normalized mean biases (*NMB*) between surface measurements and GEO satellite or GEOS-Chem values.

- Figure 8 compares the seasonalities of AOD and  $PM_{2.5}$  over the North China and South Korea regions. The GEO satellite AOD over North China peaks in July and is minimum in winter. Most of AOD is attributed by GEOS-Chem to SNA aerosol, same as in South Korea. AOD over South Korea also has a summer maximum and winter minimum but with weaker amplitude than over North China. The GEOS-Chem AOD is ~ 20% biased low in summer and this is largely due to a low RH bias (Figure S8), as seen previously in the KORUS-AQ comparisons but amplified by the high RH in summer that drives hygroscopic growth (Latimer and Martin, 2019).
- 419 Surface PM<sub>2.5</sub> in the observations over North China and South Korea shows opposite seasonality to AOD, with
- 420 minimum values in summer and maximum values in winter-spring. GEOS-Chem reproduces the strong seasonality
- 421 of PM<sub>2.5</sub> in North China and the much weaker seasonality in South Korea. The high PM<sub>2.5</sub> values over North China
- 422 in winter in the model are mostly driven by organic aerosol, reflecting the large residential coal burning source
- 423 (Figure S9; Zheng et al., 2018). In South Korea, by contrast, household energy is mainly from natural gas and
- 424 electricity (Lee et al., 2020; Woo et al., 2020). GEOS-FP daytime PBL height also shows a stronger seasonality over
- 425 North China than over South Korea (Figure S8), generally consistent with the CALIPSO daytime PBL height (Su et
- 426 al., 2018). Previous studies have shown opposite seasonality between MODIS AOD and surface PM<sub>2.5</sub> over North

- 427 China and attributed this to the seasonality in PBL height and RH (Qu et al., 2016; Xu et al., 2019). The mean
- 428 PM<sub>2.5</sub>/AOD ratio over North China in winter (236 μg m<sup>-3</sup>) is 8 times that in summer (29 μg m<sup>-3</sup>), with autumn (94 μg
- 429 m<sup>-3</sup>) and spring (89  $\mu$ g m<sup>-3</sup>) in between, while over South Korea, the PM<sub>2.5</sub>/AOD ratio in winter (62  $\mu$ g m<sup>-3</sup>) is only
- 430 70% larger than in summer (36  $\mu$ g m<sup>-3</sup>).

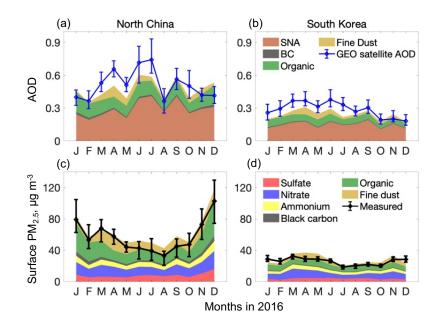

Figure 8. Seasonality of AOD and PM<sub>2.5</sub> over North China and South Korea, and contributions from individual aerosol
 components. Lines show regional medians (error bars: 25<sup>th</sup> and 75<sup>th</sup> percentiles) for the ensemble of monthly averaged

- 434 observations in the regions (Figure 6) in 2016. GEOS-Chem values are shown as stacked contours for individual
- 435 components and are sampled in the same way as the observations.

#### 436 6 Conclusions

- 437 Geostationary satellite observations of aerosol optical depth (AOD) over East Asia may usefully complement PM<sub>2.5</sub>
- 438 air quality networks if the local relationship between AOD and PM<sub>2.5</sub> can be inferred from a physical and/or
- 439 statistical model. Here we analyzed the ability of the GEOS-Chem chemical transport model to provide this
- 440 relationship by using a new fused GOCI/AHI geostationary satellite product together with AERONET ground-based
- 441 AOD measurements, aerosol vertical profiles over South Korea from the KORUS-AQ aircraft campaign (May-June
- 442 2016), and surface network observations. This allowed us to identify the critical features and limitations of the
- 443 model for successful representing the AOD-PM<sub>2.5</sub> relationship.
- 444 The KORUS-AQ observations show that total aerosol extinction (550 nm) in the vertical column is dominated by
- sulfate-nitrate-ammonium (SNA) and organic aerosol in the planetary boundary layer (PBL), despite large
- 446 concentrations of dust in the free troposphere. This reflects the optically effective size and high hygroscopicity of
- 447 the PBL aerosols. We find that GEOS-Chem aerosol optical properties based on measurements over the North
- 448 America (default model setting) underestimate KORUS-AQ aerosol mass extinction efficiency by around 20%. In

- addition, a low bias in GEOS-FP RH below 1 km leads to a 10% underestimate of AOD inferred from the aircraft
- 450 profile. Adjustments of GEOS-Chem aerosol optical properties and RH enable a successful simulation of the aerosol
- 451 extinction profile. SNA aerosol contributes 59% of column aerosol extinction in the KORUS-AO data, while
- 452 organic aerosol contributes 27% and dust contributes 12%.
- 453 Comparison of GOCI/AHI geostationary (GEO) satellite AOD to AERONET AODs over South Korea shows good
- 454 agreement, with high values along the west coast. GEOS-Chem is more consistent with the fine-mode AERONET
- 455 AOD because of its insufficient accounting of coarse particles, which account for 13% of AERONET AOD. The
- 456 remaining 15% underestimate of AERONET fine-mode AOD by GEOS-Chem can be attributed to the RH low bias.
- 457 GEOS-Chem overestimates 24-h surface PM<sub>2.5</sub> over South Korea by 43% during the KORUS-AQ period, despite its
- 458 successful simulation of the aircraft data and fine-mode AERONET AOD, and we find that this is due to a large
- 459 overestimate of nighttime nitrate.

460 Broader examination of the GOCI/AHI AOD satellite data over East Asia shows spatial distributions and

461 magnitudes consistent with AERONET and featuring in particular strong Asian outflow in spring that includes a

- 462 large dust component. We find that AODs and PM<sub>2.5</sub> have similar large-scale spatial distributions but opposite
- seasonality. PM<sub>2.5</sub> in North China has a strong winter maximum and summer minimum, while AOD shows the
- 464 opposite. GEOS-Chem simulates successfully the seasonality of measured  $PM_{2.5}$  but is ~ 20% biased low in summer
- for AOD, due again to RH low bias like that during KORUS-AQ, amplified by the high RH in summer that drives
- 466 hygroscopic growth (Latimer and Martin, 2019). We find that the opposite AOD and PM<sub>2.5</sub> seasonality is mainly
- 467 driven by residential coal heating sources and low PBL depths in winter, and high RH in summer. Observations of
- 468 PM<sub>2.5</sub> and AOD in South Korea show the same seasonal phases as in North China but with much weaker amplitude,
- 469 reflecting the lack of residential coal burning in winter and a weaker seasonal amplitude of PBL depth.
- 470 In summary, we find that the geostationary GOCI/AHI satellite AOD data provide high-quality information for
- 471 monitoring of PM<sub>2.5</sub> over East Asia but that physical interpretation requires accurate information on aerosol size
- 472 distributions, PBL depths, RH, the role of coarse particles, and diurnal variation of PM<sub>2.5</sub>, all of which are subject to
- 473 large uncertainties in chemical transport models. Addressing these uncertainties should be a target of future work.
- 474 We have used results from our study in a recent machine-learning reconstruction of daily 2011-present PM<sub>2.5</sub> over
- 475 East Asia from GOCI AOD data by identifying critical variables for the machine-learning algorithm and providing
- 476 blended gap-filling data for cloudy scenes (Pendergrass et al., 2021). Besides the factors discussed in this study,
- 477 topography might be another important factor influencing surface PM<sub>2.5</sub> and its vertical mixing (Su et al., 2018), and
- 478 this also requires future investigation.
- 479
- 480 Data availability. Aircraft data during KORUS-AQ are available at: www-air.larc.nasa.gov/cgi-
- 481 bin/ArcView/korusaq. PM<sub>2.5</sub> data over China are from: quotsoft.net/air/. PM<sub>2.5</sub> data over South Korea are from:
- 482 www.airkorea.or.kr/web. AERONET data can be found at: aeronet.gsfc.nasa.gov. The MEIC emission inventory are

- 483 at: www.meicmodel.org/. The KORUSv5 emission inventory is developed by Konkuk University, available at:
- 484 http://aisl.konkuk.ac.kr/#/emission\_data/korus-aq\_emissions.
- 485
- 486 *Author contributions*. SZ and DJJ designed the study. SZ performed the data analysis and model simulations with
- 487 contributions from JFB, KL, HCL, SKK, XW, PL, KRT, and Hong Liao. JK, SL, and Hyunkwang Lim provided
- 488 satellite AOD data. RJP and JIJ contributed to AirKorea data processing. JM and RM provided the dust emission
- 489 inventory. GL, FY, and JMM updated wet deposition simulation. JWH, BEA, JED, JLJ, PCJ, and BAN contributed
- to KORUS-AQ campaign measurements. JHW and YK provided the KORUSv5 emission inventory. QZ provided
- the MEIC emission inventory. SZ and DJJ wrote the paper with input from all authors.
