Abstract. This study aims to investigate the global, regional and seasonal temporal dust changes as well as the effect of dust particles on total aerosol loading, using the Modis Dust AeroSol (MIDAS) fine resolution dataset. MIDAS delivers dust optical depth (DOD) at fine spatial resolution ($0.1^\circ \times 0.1^\circ$) spanning from 2003 to 2017. Within this study period, the dust burden has been increased across Central Sahara (up to 0.023 yr^{-1}) and Arabian Peninsula (up to 0.024 yr^{-1}). Both regions observed their highest seasonal trends in summer (up to 0.031 yr^{-1}). On the other side, declining DOD trends are encountered in Western (down to -0.015 yr^{-1}) and Eastern (down to -0.023 yr^{-1}) Sahara, Bodélé Depression (down to -0.021 yr^{-1}), Thar (down to -0.017 yr^{-1}) and Gobi (down to -0.011 yr^{-1}) Deserts and Mediterranean Basin (down to -0.009 yr^{-1}). At spring, the most negative seasonal trends are recorded in Bodélé Depression (down to -0.038 yr^{-1}) and Gobi Desert (down to -0.023 yr^{-1}) whereas in West (down to -0.028 yr^{-1}) and East Sahara (down to -0.020 yr^{-1}), and Thar Desert (down to -0.047 yr^{-1}) at summer. Over western and eastern sector of Mediterranean Basin, the most negative seasonal trends are computed at summer (down to -0.010 yr^{-1}) and spring (down to -0.006 yr^{-1}), respectively. The effect of DOD on the total aerosol optical depth (AOD) change is determined by calculating the DOD to AOD trends ratio. Over Sahara Desert the median ratio values range from 0.83 to 0.95 whereas in other dust affected areas (Arabian Peninsula, South Mediterranean, Thar and Gobi Deserts) the ratio value is approximately 0.6. In addition, a comprehensive analysis of the factors effecting the sign, the magnitude and the statistical significance of the calculated trends is conducted. Firstly, the implications between the implementation of geometric mean instead of arithmetic mean to trend calculations are discussed revealing that the arithmetic-based trends tend to overestimate compared with the geometric-based trends both over land and ocean. Secondly, an analysis interpreting the differences in trend calculations under different spatial resolutions (fine and coarse) and time intervals is conducted.

30 1 Introduction

31 Dust particles emitted from natural or anthropogenic sources are a major contributor to the atmospheric aerosol burden in
32 terms of mass (Zender et al. 2004; Textor et al., 2006; Kok et al., 2017). Among aerosol properties, AOD describes adequately
33 aerosols' load, in optical terms, corresponding to the entire atmospheric column. The proportion of AOD attributed to dust
34 particles consists the DOD. The spatiotemporal patterns of mineral particles are determined by the dust life cycle components,
35 characterized by a pronounced heterogeneity (Mahowald et al., 2014). The main natural dust sources are located in the northern
36 hemisphere (Goudie and Middleton., 2006), with Sahara region being the most dominant one (Prospero et al., 2002; Goudie
37 and Middleton, 2006; Rajot et al., 2008; Alizadeh-Choobari et al., 2014a). Other active source areas of mineral particles are
38 situated in the Middle East and the region stretching from Mesopotamia to the Oman coasts in south Arabian Peninsula
39 (Prospero et al., 2002; Ginoux et al., 2012), in southwest Asia and Sistan Basin (Iran-Pakistan-Afghanistan) (Alizadeh-
40 Choobari et al., 2014b; Rashki et al., 2015), in Central Asia across the Karakum (Turkmenistan-Uzbekistan) and Kyzylkum
41 Deserts (southeast of the Aral sea in Uzbekistan) (Elguindi et al., 2016), in East Asia with Taklamakan (Tarim basin in
42 northwest China) and Gobi (north China – south Mongolia) deserts (Ginoux et al., 2012), and in North America with Black
43 Rock and Smoke, Great Salt Lake, and Chihuahuan and Sonoran deserts (Ginoux et al., 2012).

44 Mineral dust aerosols are uplifted, accumulated into the atmosphere, and transported over enormous distances (up to some
45 thousands of kilometers) from their sources (Goudie and Middleton., 2006) driven by the prevailing winds. Schepanski et al.
46 (2018) reported that the transport distance of dust particles is strongly related to their residence time, which is analogous to the
47 dust lifetime, dust layer altitude, atmospheric circulation pattern, buoyancy and gravitational forces. van der Does et al. (2018)
48 also denoted that strong winds, turbulence, electrostatic forces developed by dust particles' charging, and thunderstorms or
49 tropical cyclones may potentially enhance the residence time of dust aerosols into the atmosphere. On a seasonal basis, dust
50 particles can be transported from north Africa towards the Atlantic Ocean reaching Caribbean, Central America, southern
51 United States (in boreal summer) and South America (in spring and winter) (Griffin et al., 2002; Prospero and Lamb., 2003;
52 Kalashnikova et al., 2008; Huang et al., 2010; Tsamalis et al., 2013; Prospero and Mayol-Bracero., 2013). Additionally,
53 Saharan dust is advected towards the Mediterranean and Europe (Mona et al., 2006; 2012, Papayannis et al., 2008; Basart et
54 al., 2009; Schepanski et al., 2018; Gkikas et al. 2015; 2016, Logothetis et al., 2020, 2021).

55 During the last decades, numerous studies have been conducted using observations from various satellite sensors. Prospero
56 et al. (2002) and Ginoux et al. (2012) identified the global dust sources relying on Total Ozone Mapping Spectrometer (TOMS,
57 Torres et al., 2002) and Moderate Resolution Imaging Spectroradiometer (MODIS, Remer et al., 2008), respectively. More
58 specifically, the studies of Prospero et al. (2002) and Ginoux et al. (2012) were based on the frequency of occurrence (FoO)
59 of TOMS absorbing aerosol index (AAI) and MODIS-based DOD, respectively, exceeding defined thresholds. In addition,
60 Ginoux et al. (2012) associated the dust frequency with three clusters such as hydrologic and non-hydrologic natural or
61 anthropogenic in order to distinguish the dust origin. Similarly, at a regional scale, Schepanski et al. (2012) implemented a
62 comprehensive analysis on the potential differences of Saharan dust active sources within the intercomparison of aerosol

properties observations derived from MODIS, Meteosat Second Generation (MSG) and Ozone Monitoring Instruments (OMI). Voss and Evan (2020) presented a global DOD climatology, both over land and ocean, using MODIS (Aqua and Terra) from 2001 to 2018 and Advanced Very High Resolution Radiometer (AVHRR) over ocean from 1981 to 2018. Similarly, Clarisse et al. (2019) performed a global seasonal DOD climatology relying on Infrared Atmospheric Sounding Interferometer (IASI) retrievals, during the 2008–2017. Yu et al. (2019), derived DOD using MODIS, IASI and Multiangle Imaging Spectroradiometer (MISR) and in conjunction with dust vertical profiles from Cloud–Aerosol Lidar with Orthogonal Polarization (CALIOP) (Shikwambana and Sivakumar., 2018) investigated the dust deposition and loss frequency across the Tropical Atlantic Ocean on a seasonal basis.

The investigation of dust loads' variation at interannual time scales is quite critical for assessing the associated impacts on climate as well as the response of these tendencies to environmental factors. Since the majority of remote sensing instruments provide an AOD product, numerous studies on a global scale, are focused on the estimation of AOD temporal trends, which are not always representative of DOD, being mixed with other aerosol types (Zhang and Reid, 2010; de Meij et al., 2012; Hsu et al., 2012; Yoon et al., 2014; Pozzer et al., 2015; Alfaro-Contreras et al., 2017; Zhao et al., 2017; Che et al., 2019) and regional scales (Guo et al., 2011; Li, 2014; Klingmüller et al., 2016; Floutsi et al., 2016; Dahutia et al., 2017; Hu et al., 2018; Zhang et al., 2018). Limited satellite studies are dedicated to the estimation of DOD temporal trends due to the deficiency to quantify accurately the portion of AOD attributed to DOD. Prior studies have investigated the interannual patterns of DOD over the “dusty” regions of the planet. Dust load has been increased across the Sahara Desert, based on MODIS-Aqua derived DOD dataset during 2003–2018 (Voss and Evan 2020). Notaro et al. (2015) detected a regime shift in dust activity between 1998–2005 (inactive dust period) and 2007–2013 (active dust period) across Arabian Peninsula, which is attributed to the prolonged drought along the Fertile Crescent. Through the synergy of MISR DODs and back trajectories, they revealed that the positive DOD anomalies (increased dust burden) are strongly connected with dust advection from the Fertile Crescent towards the Arabian Peninsula. These findings are consistent with the strong positive AOD (Klingmüller et al., 2016) and DOD (Voss and Evan 2020) trends reported in the area. Voss and Evan (2020), found a reduction of dust load across the Northern African coasts over the period 2001–2018, based on MODIS-Terra DOD dataset. Declining DOD trends have also been reported in Central Asia by Xi and Sokolik (2015), who analyzed MODIS and Sea-viewing Wide Field-of-view Sensor (SeaWiFs) DODs for a 15-year period (2000-2014). DOD trend sign is also abruptly changed from positive (1999-2009) to negative (2010–2016) over East Asia and North Pacific Ocean in springtime, based on Modern-Era Retrospective Analysis for Research and Applications, Version 2 (MERRA-2) (Gelaro et al., 2017) measurements (Guo et al., 2019). Across South Asia, a negative shift in DOD interannual variation is recorded during the pre-monsoon season between 2008–2012 and 2013–2017, based on CALIOP observations (Lakshmi et al., 2019). In the southern sector of the Gobi Desert, declining DOD trends are observed from MODIS and CALIOP DOD datasets during 2007–2019 (Song et al., 2021).

This study's main objective is to investigate the dust temporal variations at global, regional, and seasonal scales, using the newly MIDAS DOD product from 2003–2017. A few aspects regarding the innovative points of this research are highlighted below to support the scientific contribution to the relevant research field. First, in contrast to the existing studies, this trend

analysis relies on fine spatial resolution data, making it feasible to depict in detail the spatial patterns of the DOD variations. Such information can be critical for interpreting the perturbations of the radiation fields, environmental impacts, and health effects attributed to dust particles. One more advantage of the high resolution DOD analysis is the flexibility of the final grid size selection depending on data availability, which is a critical aspect when satellite observations are used. MIDAS data can be easily upscaled at coarser spatial resolutions in order to match spaceborne observations, which have been commonly used in other trend analyses available in the literature (Hsu et al., 2012; Yoon et al., 2014; Notaro et al., 2015; Pozzer et al., 2015; Klingmüller et al., 2016; Alfaro-Contreras et al., 2017; Che et al., 2019; Guo et al., 2019; Voss and Evan 2020; Song et al., 2021). In addition, fine spatial resolution data ensure a more realistic collocation with ground-based measurements for validating the obtained DOD trends. Second, quite a few studies concentrate on pure DOD (Xi and Sokolik 2015; Guo et al., 2019; Lakshmi et al., 2019; Voss and Evan 2020; Song et al., 2021) rather than AOD to analyze the trends of mineral particles' load. Even though the consideration of the latter parameter is quite reasonable across deserts, its representativeness over downwind areas is questionable due to the coexistence of other aerosol types. Such types can also affect the DOD trend uncertainty. In MIDAS, this issue is addressed by the adjustment of MODIS AOD to DOD in terms of the MERRA-2 dust fraction, while in other studies, aerosol size and natural optical properties, which their quality above land is downgraded, are used in parallel. Third, taking advantage that MIDAS provides DOD and quality assured AOD, their trends are discussed jointly for assessing the contribution of dust burden temporal variations to those of the total aerosol load. It should be mentioned that this is the first study assessing the effect of DOD to total AOD trends across the major desert dust areas of the planet, highlighting the potential role of desert dust particles in past, present, and future AOD trend studies. Fourth, the investigation of the potential impact on trends' magnitude, sign, and statistical significance when different DOD aggregations (i.e. arithmetic mean vs. geometric mean) are considered among various spatial and temporal scales. Fifth, the DOD interannual variations are discussed for the entire study period on a seasonal basis and sub-periods for detecting alternations on DOD trends within the period of interest.

The current paper is organized as follows. Sect. 2 describes the (i) MIDAS (Sect. 2.1) and (ii) AERONET (Sect. 2.2) datasets as well as the trend detection methodology (Sect. 2.3). The results section (Sect. 3) is divided into three sub-sections analyzing (i) the global AOD and DOD tendencies (3.1), along with the sensitivity analyses between arithmetic and geometric means (3.1.1), fine ($0.1^\circ \times 0.1^\circ$) and coarse ($1^\circ \times 1^\circ$) spatial resolutions (Sect. 3.1.2), MIDAS DOD and AERONET retrievals (Sect. 3.1.3), and filtered and non-filtered data trend calculations (Sect. 3.1.4), (ii) global dust temporal trends on a seasonal basis (Sect. 3.2), and (iii) DOD temporal tendencies into specific regions (Sect. 3.3). Finally, a discussion focusing on the main findings of this study is presented in the summary and conclusion section (Sect. 4). The current study represents a practical implementation of the MIDAS dataset and aims to demonstrate its feasibility on the estimation of dust load variation at various temporal and spatial scales.

128 **2 Data and Methods**

129 **2.1 Modis Dust AeroSol (MIDAS) dataset**

130 MIDAS dataset (Gkikas et al., 2021a) provides columnar DOD at 550 nm, on a daily basis over the 15-year period
131 spanning from 2003 to 2017, at a global scale and fine spatial resolution ($0.1^\circ \times 0.1^\circ$). Its development has relied on the
132 synergistic implementation of quality filtered AOD retrievals from MODIS-Aqua (Level 2; Collection 6.1) and MERRA-2
133 dust fraction (MDF), both reported at 550 nm. More specifically, the multiplication of MODIS-Aqua AOD with MDF provides
134 the MIDAS-DOD on MODIS native grid which is converted to an equidistant lat-lon projection. In order to justify the
135 reliability of MDF, it has been evaluated against the corresponding portion provided by the LIVAS database (Amiridis et al.,
136 2013; 2015). Based on the aforementioned assessment analysis, it has been revealed an adequate representation of MERRA-2
137 dust fraction, in optical terms, over the main dust sources and the outflow regions, in contrast to areas where dust presence is
138 weak. Therefore, the combination of highly accurate MODIS AODs (Wei et al., 2019b) and quite reliable MDF results in a
139 trustworthy MIDAS DOD product as it has been justified via its evaluation against AERONET dust-like AOD and its
140 intercomparison versus DOD derived by LIVAS and MERRA-2. For the former analysis, the ground-based AODs have been
141 treated appropriately in order to resemble DOD, as much as possible, assuming that the contribution of fine mineral particles
142 is negligible and trying to minimize the contribution of non-dust aerosol species to the columnar aerosol load. Under these
143 assumptions, the evaluation metrics, both at global and station level, reveal a quite high level of agreement between the two
144 datasets. At global scale, there is a high level of agreement between MIDAS and AERONET DODs as indicated by the high
145 correlation (~ 0.9) and the low positive bias (0.004 or 2.7%). Across the ‘dust belt’, the correlation coefficients can reach up to
146 0.98 at station level whereas positive biases (mostly lower than 0.06) are found. Outside of this zone, the correlation reduces,
147 and the biases of similar magnitude are switching to negative. Likewise, it has been evident a considerable consistency among
148 MIDAS, LIVAS and MERRA-2 DODs at global and hemispherical scales, despite the different approaches applied for the
149 DOD derivation, whereas the intercomparison results are regionally dependent. Summarizing, the reliability of the MIDAS
150 DOD justified in Gkikas et al. (2021a) strengthens its applicability for investigating the temporal trends of dust aerosol burden
151 over long-time periods and at various spatial scales.

153 **2.2 AERONET**

154 On a regional basis, the reliability of MIDAS DOD trends has been evaluated using ground-based measurements from
155 AERONET (Holben et al., 1998). AERONET provides information for the spectral columnar AOD using direct spectral solar
156 irradiance. In addition, the physical and optical properties of aerosols can be derived by applying the Dubovik and King (2000)
157 inversion algorithm. DOD ground-based measurements can be approached using AERONET retrievals, however, an aerosol
158 classification scheme is mandatory. Through MIDAS evaluation procedure, the discrimination of dust load from non-dust
159 aerosol species has been performed in terms of the Ångström wavelength exponent at 440-870 nm ($AE_{440-870 \text{ nm}}$) and the

160 difference between single scattering albedo at 440 nm ($SSA_{440\text{ nm}}$) and 675 nm ($SSA_{675\text{ nm}}$). $AE_{440-870\text{ nm}}$ has been used as an
161 indicator of particles size (coarse or fine aerosols) in numerous aerosol classification studies (Basart et al., 2009; Mielonen et
162 al., 2009; Lee et al., 2010; Giles et al., 2012; Hamill et al., 2016; Zheng et al., 2017; Che et al., 2018; Logothetis et al., 2020).
163 In addition, the aerosols origin can be acquired using either the difference between SSA at different wavelengths or specific
164 spectral SSA thresholds. In Gkikas et al. (2021a), the pure dust conditions have been succeeded using a very restricted threshold
165 limit of $AE_{440-870\text{ nm}} (\leq 0.75)$ along with a positive difference of $SSA_{675\text{ nm}} - SSA_{440\text{ nm}}$. Despite the favorable dust conditions
166 retrieved through the SSA retrievals, the data availability strongly decreases causing difficulties in trend calculations. In the
167 current study, the evaluation of MIDAS DOD trends is performed by using the AERONET coarse mode AOD at 500 nm,
168 derived from the spectral deconvolution algorithm (SDA) (O'Neill et al., 2001, 2003). The performance of the SDA algorithm,
169 in terms of segregating the fine and coarse aerosol modes, has been justified against ground-based observations (Kaku et al.,
170 2014). Only quality assured data (cloud-screened), including pre-field and post-field calibrations (Level 2.0, L2) from
171 AERONET Version 3 (V3) (Giles et al., 2019) are used. It should be mentioned that cAOD does not represent profoundly the
172 dust load due to the presence of sea-salt particles.

173

174 2.3 Temporal trends methodology

175 The spatiotemporal changes of dust particles' burden, over the period 2003 – 2017, are investigated by calculating the
176 annual trends derived by the monthly MIDAS DODs. At each grid-cell, the monthly DOD averages are calculated when the
177 20% (≥ 6 days) of daily data are available (Hsu et al., 2012). Subsequently, at the grid points with more than 60 months
178 available (5 out of 15 complete years) linear trends are calculated by the implementation of the following equation,

$$179 Y_t = \mu + S_t + \omega X_t + N_t \quad (1)$$

180 where Y_t is the monthly averaged values, μ the offset term, S_t is the seasonal term (i.e. long-term monthly value), ω the linear
181 trend and N_t the residuals. The seasonality is removed by subtracting S_t from Y_t . The statistical significance of ω is derived
182 according to Weatherhead et al. (1998). N_t follows a 1st-order autoregressive process (significant lag-1 autocorrelation),

$$183 N_t = \varphi N_{t-1} + \varepsilon_t \quad (2)$$

184 with ε_t is the white noise and φ the lag-1 autocorrelation coefficient. The standard deviation of the trend can be expressed as,

$$185 \sigma_\omega \approx \frac{\sigma_N}{n^{3/2}} \sqrt{\frac{1+\varphi}{1-\varphi}} \quad (3)$$

186 where σ_N is the standard deviation of N_t and n is the number of complete years depending on the data availability at each grid
187 cell without always considering the entire period (i.e. a constant value of 15 years). When $|\omega/\sigma_\omega| > 2$, significant temporal trends
188 are considered at a 95% confidence level. The methodology of Weatherhead et al. (1998) is commonly applied in numerous
189 studies concerning the detection of temporal trends in AOD (Hsu et al., 2012; Babu et al., 2013; Li et al., 2014; Kumar et al.,

190 2015, 2018; Pozzer et al., 2015; Adesina et al., 2016; Alfaro-Contreras et al., 2017; Zhang et al., 2018; Ningombam et al.,
191 2019). Additionally, for comparison purposes with previous studies, AOD and DOD linear trends are calculated also at 1°
192 spatial resolution. The re-gridding procedure from fine to coarse spatial resolution is implemented following Levy et al. (2009)
193 (upper branch in Fig. 5 of their publication). For the calculation of regional trends (Sect. 3.3), the same approach is adopted.
194 First, daily spatial grids of 0.1° are temporally averaged to create monthly data. Then, monthly grids with 1° spatial resolutions
195 are generated using a weighted aggregation of monthly fine grids. The weighting factors are defined in terms of latitude. More
196 specifically, this weighting scheme considers the fraction between the area covered by each fine grid-cell to the total available
197 surface area within the coarse grid-cell.

198 The appropriate selection of the statistical average metric (e.g. arithmetic or geometric mean) is reflected to the
199 background probability distribution which the raw data are resembled. For instance, the vast majority of the studies focusing
200 on AOD statistics have thoroughly consider that AOD follows a Gaussian distribution using the simple arithmetic mean for
201 temporal and spatial aggregations. Nevertheless, the frequency distribution of AOD follows is more well fitted to the log-
202 normal distribution (O' Neill et al., 2000). Sayer and Knobelspiesse (2019) designated that the calculation of the geometric
203 instead of the arithmetic mean for obtaining temporal and spatial AOD trends may underestimate them comparing to those
204 reported in the literature. Here, in order to investigate the potential differences on AOD and DOD temporal trends, a sensitivity
205 analysis using both geometric and arithmetic mean is established. MIDAS dataset includes negative DOD values introduced
206 from the applied Dark Target algorithm of MODIS AOD retrievals. Since zero or negative arguments of logarithm cannot be
207 defined, all these values are overwritten to 0.0001 as suggested by Sayer and Knobelspiesse (2019).

208 **3 Results**

209 This section is divided into three main parts. Sect. 3.1 describes the geographical distribution of AOD and DOD trends,
210 at global scale, by performing simultaneously a sensitivity analysis on: (i) the aggregation metric (geometric vs. arithmetic
211 mean), (ii) the spatial resolution (fine vs. coarse), (iii) MIDAS trends evaluation (DOD vs. cAOD trends), and (iv) the applied
212 temporal criteria (filters vs no filters). In Sect. 3.2, focus is given on the seasonal DOD trends whereas in Sect 3.3 emphasis is
213 given on DOD trends at 12 regions of interest.

214 **3.1 Global trends**

215 **3.1.1 Geometric vs. arithmetic mean**

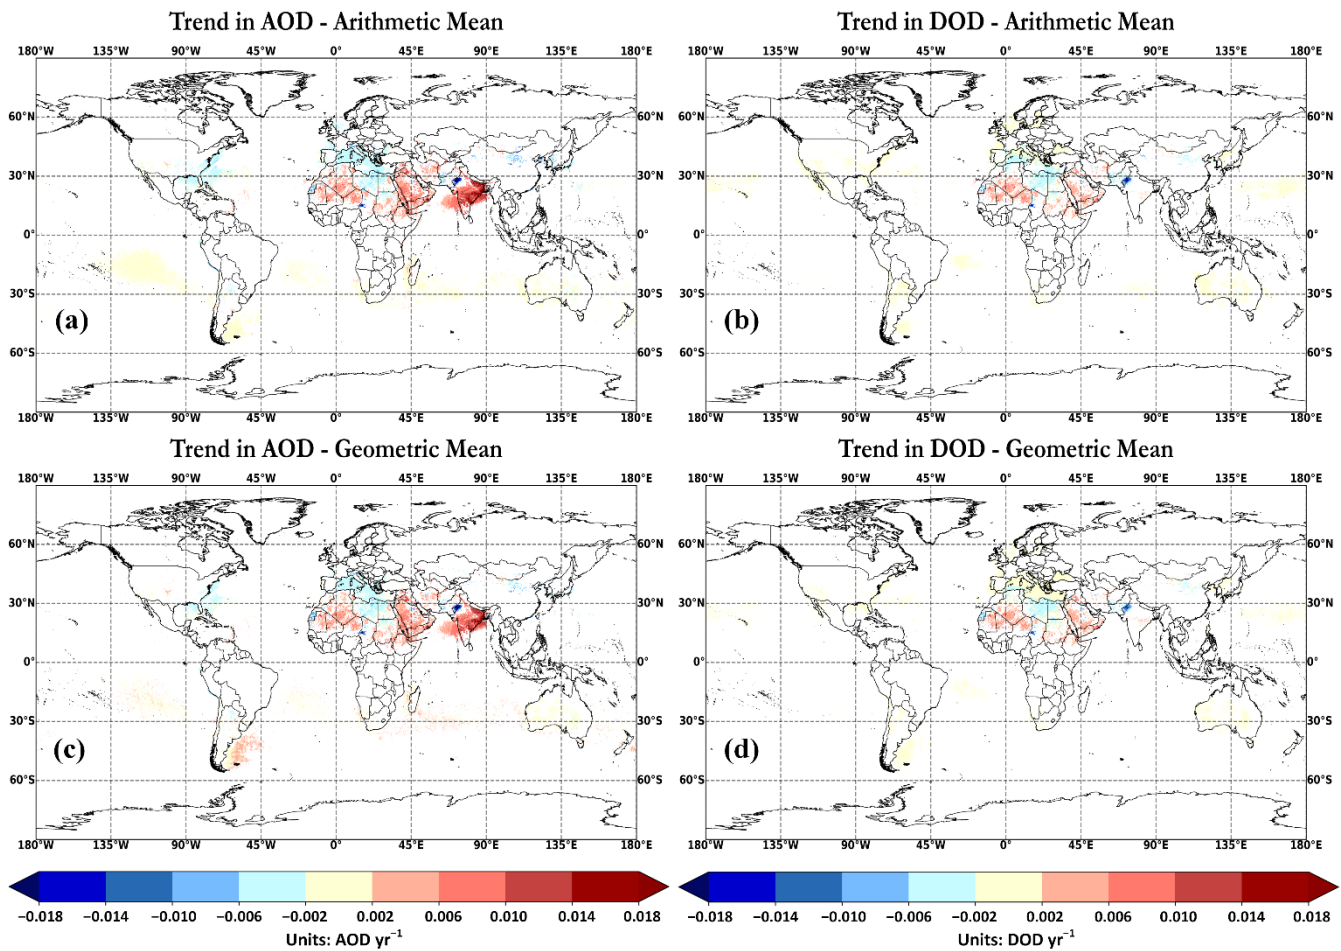

216 The overwhelming majority of the published AOD/DOD trend analysis studies have been relied on arithmetic mean in
217 order to produce coarser spatial (e.g. $1^\circ \times 1^\circ$) and temporal (e.g. monthly values) resolutions. In this study, a sensitivity analysis
218 on the aggregation method (i.e. arithmetic vs geometric mean), has been performed by utilizing the daily coarse spatial
219 resolution ($1^\circ \times 1^\circ$) MIDAS DODs. Figure 1 depicts the frequency histogram of MIDAS DODs in log scale using all the
220 available data over the period 2003–2017. It is apparent that the shape of the DOD distribution is close to a log-normal

221 distribution (Fig. 1). The latter considers the extreme dust episodes which force the distribution curve to be right-skewed.
 222 Arithmetic mean is about 4 times higher than the geometric mean, highlighting the importance of which metric is more
 223 representative of the population and how this can affect the results for specific applications (e.g. radiative forcing). When
 224 geometric standard deviation is considered, 65.43% of DOD values range between 0.002 and 0.027 while 81.04% encompassed
 225 within -0.033 and 0.099 for arithmetic mean, indicating an overstating of the variability (Sayer and Knobelspiesse, 2019). The
 226 averages and the standard deviations are calculated using weighted aggregation expressions with the weighting factors in terms
 227 of latitude (see Sect. 2.3). An additional point, revealing that the selection of normal statistics can lead to a misrepresentation
 228 of the population for a positive-definite quantity (i.e. dust optical depth), is that the lower bound (-0.033) is negative, which
 229 has not any physical meaning.

230
 231 **Figure 1. Frequency histogram of MIDAS DODs reported at $1^\circ \times 1^\circ$ spatial resolution over the period 2003 – 2017. The computed**
 232 **geometric mean (green) and arithmetic mean (blue) are given along with ranges corresponding to geometric mean/geometric**
 233 **standard deviation and geometric mean*geometric standard deviation for the geometric mean and \pm standard deviation for the**
 234 **arithmetic mean.**

235 In agreement with Sayer and Knobelspiesse (2019), the calculated trends for AOD and DOD are consistent in terms of
 236 sign between fine (Fig. 2) and coarse (Fig. 3) spatial resolution data. However, in terms of magnitude this is not the case.
 237 Figure S1, S2 depicts the frequency histograms of the deviations between the arithmetic and geometric trends. When geometric
 238 AOD/DOD averages are considered, the deseasonalized trends are suppressed by up to 91.77% with the respect to the
 239 corresponding levels obtained from the arithmetic means, regardless the underlying surface type. The only exception is found
 240 for AOD at 1° spatial resolution and across oceanic territories (Fig. S2c) where geometric trends overestimate those of
 241 arithmetic by 71.63%.

243

244 **Figure 2: Global maps of temporal trends (statistically significant at 95% confidence level), at $0.1^\circ \times 0.1^\circ$ spatial resolution, calculated**
245 **from the deseasonalized AOD (a and c) and DOD (b and d) monthly values during 2003 – 2017. Upper panel (a, b) shows the**
246 **arithmetic-based trends while the bottom panel (c, d) indicates the geometric-based trends. The pixels with: 1) non-significant trends,**
247 **2) the temporal criteria are not met and 3) not available data are colored as white (blank) in each map of trend analysis. Neutral**
248 **trends, ranging between -0.002 and 0.002 DOD yr^{-1} , are colored with light yellow (or cream) (the central color of the color bar).**
249 **Figs S3a, S3b and S4 present the differences between the aforementioned colors at fine, coarse spatial resolution as well as for the**
250 **seasonal trends, respectively. Based on those Figs, the pixels with not available data are colored with gray color while those of failing**
251 **to meet the availability criteria are colored with greenish.**

252

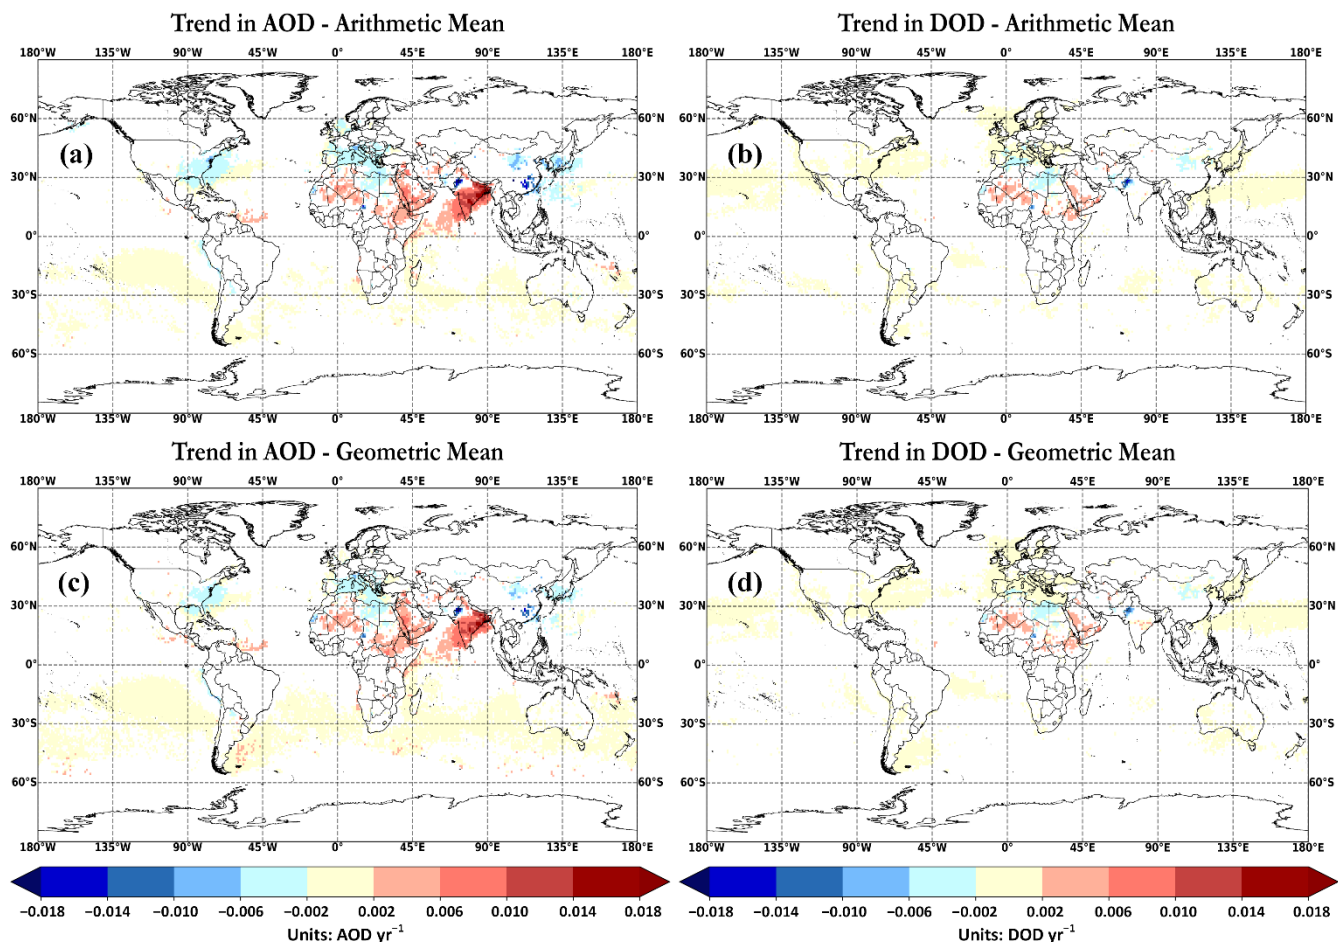

Figure 3: Same as Fig. 2 at 1° x 1° spatial resolution.

Across the dust-affected regions of the planet, the calculated AOD and DOD trends have revealed similar pattern. Over areas where the dust contribution to the total aerosol load is negligible, DOD trends are non-significant or neutral. For instance, strong positive AOD trends are depicted across India and the Bay of Bengal (Figs. 2a and 2c), whereas the recorded annual DOD tendencies are negligible (Figs. 2b and 2d). Similar findings are evident along the eastern coasts of US and in the Gulf of Mexico. In the Mediterranean Basin, engrossing disparities are recorded between AOD and DOD trends. Negative AOD trends are shown in the entire region with decreasing DOD trends confined in the southern areas near the North Africa coast (Figs. 2b and 2d). In addition, strong positive trends for AOD and DOD are revealed in Central Sahara (up to 0.026 yr^{-1}), across Mauritania-Algeria-Mali-Niger areas and the Arabian Peninsula. The highest positive tendencies are shown in Oman–Saudi Arabia borders (up to 0.031 yr^{-1}). On the contrary, decreasing AOD/DOD tendencies are observed in the Eastern (down to -0.017 yr^{-1}) and Western (down to -0.019 yr^{-1}) Sahara, in the Bodélé Depression of the Chad Basin (northern of Lake Chad), in the Gobi Desert (Northern China–Southern Mongolia) as well as in the Thar Desert (northwestern Indian subcontinent). Among the regions where declining tendencies are evident, the most negative ones are recorded in the Bodélé

267 Depression (down to -0.025 yr^{-1}) and in the Thar Desert (down to -0.029 yr^{-1}). A comprehensive regional analysis including
268 the intercomparison with prior findings and the potential trends justification is discussed in Sect. 3.3.

269

270 3.1.2 Fine vs. coarse spatial resolution

271 The second sensitivity analysis aims to highlight differences of AOD/DOD trends when fine and coarse spatial resolution
272 of MIDAS data are contrasted. De Meij et al. 2012 have investigated the differences between the fine daily MODIS AOD (L2;
273 at $0.1^\circ \times 0.1^\circ$ spatial resolution) and the coarse monthly MODIS AOD (L3; at $1^\circ \times 1^\circ$ spatial resolution) in trend calculations
274 utilizing the Collection 5 (C005) retrievals. According to their study, a good agreement was found between the L2 and L3
275 AOD trends over specific areas (i.e. Central Mediterranean, North-East America, and East Asia). At a first glance, the trend
276 patterns reproduced by the fine (Fig. 2) and coarse (Fig. 3) MIDAS DODs are spatially consistent. Nevertheless, in terms of
277 magnitude, the absolute values of DODs at coarser spatial resolution are lower in most of areas with evident signal (either
278 positive or negative), such as the southern parts of the Arabian Peninsula (up to 0.014 yr^{-1}), the Bodélé Depression (down to
279 -0.015 yr^{-1}) and the Thar Desert (down to -0.024 yr^{-1}). Coarser grid-cells in contrast to the finer spatial resolution meet the
280 data availability threshold (≥ 60 months) (Fig. S3) defined for the calculation of temporal trends because of their more
281 extensive spatial coverage. MIDAS meets adequately the temporal criteria (Sect. 2.2) both at fine (Fig. S3a) and coarse (Fig.
282 S3b) spatial resolutions, providing grid cells of long-term AOD/DOD time series along with significant AOD (Figs. 2a, 2c, 3a
283 and 3c) and DOD (Figs. 2b, 2d, 3b and 3d) tendencies. Trend analysis for the coarse grids yields a superior number of
284 significant AOD tendencies globally (Figs. 3a and 3b). For instance, new and significant declining coarser AOD trends are
285 observed in East Asia, particularly across Southeast Asia, the Yellow Sea, the Sea of Japan, and the North Pacific Ocean.
286 Similarly, new increasing AOD trends are reported in the Southern Arabian Sea and the North Atlantic Ocean nearby the coast
287 of Venezuela.

288 Voss and Evan (2020) generated two global DOD datasets using MODIS retrievals, combined with reanalysis data and
289 AERONET inversion retrievals. They estimated the decadal DOD trends (see their Figs. 11a and 11b) based on MODIS/Terra
290 (2001–2018) and MODIS/Aqua (2003–2018) data projected at an equal lat-lon 1° spatial resolution. In order to compare the
291 findings in this study against Voss and Evan (2000), only arithmetic DOD trends are used at the same grid-cell spatial resolution
292 (Fig. 3b). In addition, since MIDAS dataset relies on MODIS-Aqua retrievals (Sect. 2.1), only their DOD MODIS/Aqua dataset
293 is used for comparison. Table 1 displays the ranges of DOD trends between the two datasets over 15 desert and downwind
294 areas of the globe. The selection of the above regions is accomplished based on the areas in which statistically significant DOD
295 trends are revealed in Voss and Evan (2020) study. Over the Sahara Desert, Bodélé Depression and Thar desert, identical
296 significant trends in terms of magnitude and sign are recorded in both studies. Over Arabian Peninsula, the calculated trends
297 here are common in terms of sign but lower in terms of magnitude. More specifically, the current study reports declining DOD
298 trends along the Mediterranean Basin, while Voss and Evan (2020) did not find any significant trends. On the other side, they
299 reported strong positive trends over Tropical Atlantic Ocean, sub-Sahel, Northeast Middle East and Northeast Caspian and

300 Aral Sea which is not the case here. Trend inconsistencies are revealed because of a) the derivation algorithm of DOD, b) the
 301 trend detection methodology, c) the different study periods, and d) the temporal filtering criteria.

302 **Table 1: Comparison of the computed DOD trends between the current study and the Voss and Evan (2020) over 15 regions of**
 303 **interest.**

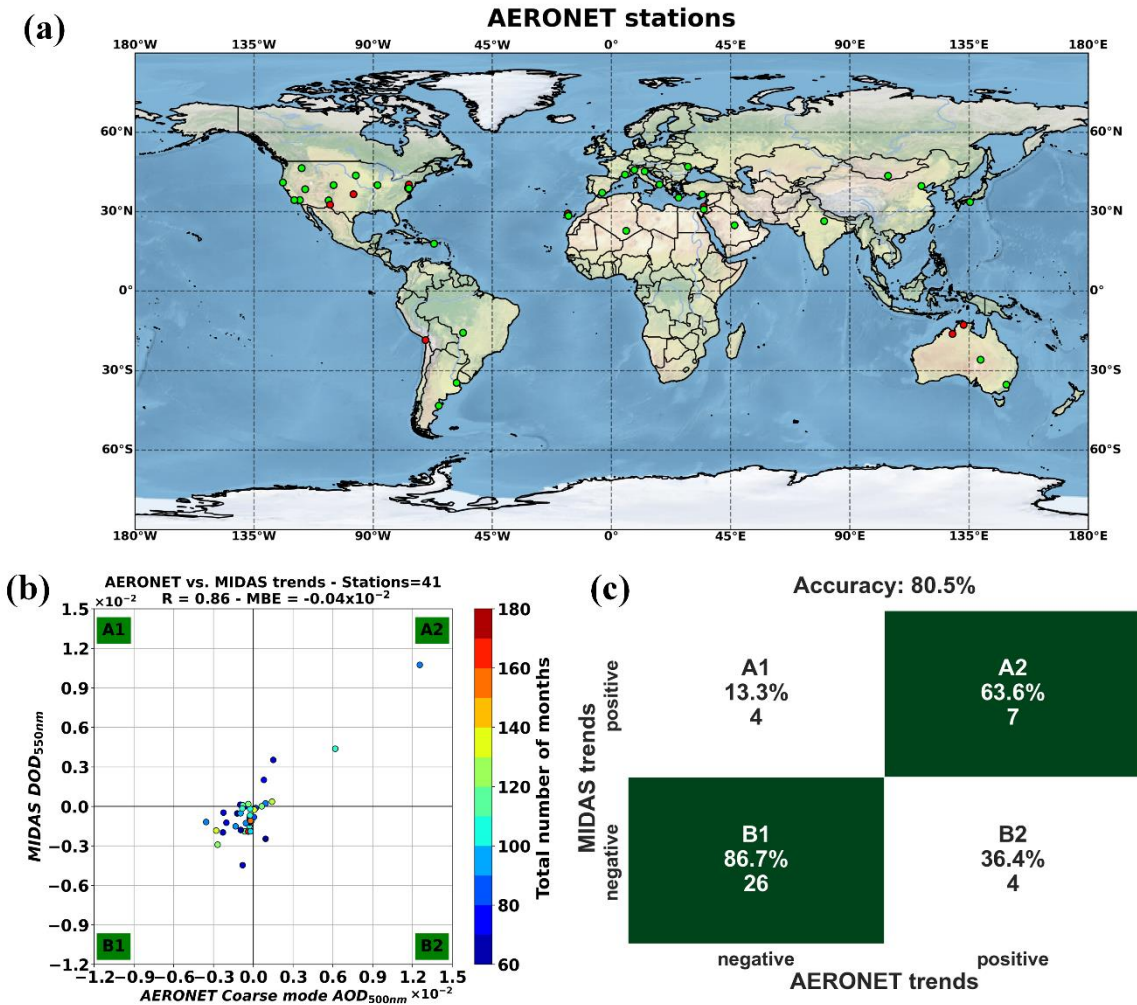

Regions	Latitude (°)	Longitude (°)	Current study (DOD yr ⁻¹)	Voss and Evan (2020) (DOD yr ⁻¹)
Desert areas				
West Sahara	21 – 26 N	12 – 16 W	–0.010 – – 0.002	–0.010 - –0.002
Central Sahara	15 – 30 N	10 W – 15 E	0.002 - 0.010	0.002 - 0.010
East Sahara	18 – 30 N	15 – 30 E	–0.006 – – 0.002	–0.006 – – 0.002
Bodélé Depression	13 – 16 N	12 – 18 E	–0.018 – – 0.002	–0.018 – – 0.002
Middle East	10 – 35 N	35 – 50 E	0.002 - 0.018	0.002 - 0.021
Thar Desert	24 – 30 N	68 – 76 E	–0.018 – – 0.002	–0.021 – – 0.002
Gobi Desert	37 – 45 N	90 – 110 E	–0.006 – – 0.002	–0.010 – – 0.002
Downwind areas				
Sub-Sahel	0 – 13 N	60 W – 20 E	Non-significant	0.002-0.018
Mediterranean Basin	30 – 45 N	10 W – 30 E	–0.006 – – 0.002	–0.002 - 0.002
Region surround Caspian Sea	35 – 60 N	45 – 60 E	Non-significant	0.002 - 0.021
Tropical Atlantic Ocean	0 – 15 N	20 – 60 W	Non-significant	0.002 - 0.006
South Atlantic Ocean	30 S – 0	13 W – 13 E	Non-significant	–0.006 - 0.006
North Pacific Ocean	40 – 60 N	140 E – 120 W	Non-significant	–0.010 – – 0.010
North Pacific and North America	15 – 40 N	140 E – 75 W	–0.002 - 0.002	–0.002 - 0.002
South Pacific Ocean	45 – 15 N	160 E – 80 W	–0.002 - 0.002	–0.002 - 0.002

304

305 **3.1.3 Evaluation of MIDAS trends vs. AERONET**

306 The validity of the computed MIDAS DOD trends is thoroughly analyzed in this section. For evaluation purposes, the
 307 coarse mode AOD, hereafter referred as cAOD, retrieved through the AERONET SDA algorithm is applied. The two datasets
 308 are collocated by spatially averaging MIDAS DODs included in an area of 3x3 pixels around each AERONET site, and also
 309 temporally combined using solely the same daily values. DOD and cAOD trends are calculated using the methodology
 310 described in Sect. 2.3. Figure 4a illustrates the geographical distribution of the AERONET stations (in total 41) satisfying the

311 defined temporal criteria (see Sect. 2.3) and finally used in the assessment analysis. According to Fig. 4b, a good linear
 312 correlation ($R = 0.86$) of the derived trends is observed accompanied with low bias ($MBE = -0.04 \times 10^{-2}$). In order quantify the
 313 performance of MIDAS in capturing the cAOD trends, the total accuracy (TA) of the correct trends (identical sign) is
 314 calculated. More specifically, TA is defined as the percentage of the stations with correct trends sign (the sum of B1 and A2
 315 quadrants numbers in Fig. 4c divided by the total number of stations). MIDAS trends can capture the correct cAOD trends
 316 signs with a TA of 80.5% (Fig. 4c). In addition, the percentages of each quadrant in Fig. 4c shows the number of the correctly
 317 detected stations per sign. The overwhelming majority of the AERONET stations encompassed negative trends (30 out of 41
 318 stations). MIDAS trends capture the 26 out of those 30 (86.7%) stations denoted with negative cAOD trends. Lastly, there are
 319 only 11 sites with positive cAOD trends, and MIDAS proved able to detect them at 7 out of 11 (63.6%) stations.

343 **Figure 4:** (a) Geographical location of the available AERONET stations in which the temporal trends of DOD and cAOD are
 344 calculated. Green and red dots refer the stations with the similar and different trend sign, respectively. (b) Scatter plot between

345 MIDAS DOD and AERONET cAOD trends. The color bar indicates the total number of months. (c) Confusion matrix of possible
346 trend signs among the two datasets.

347 Table S1 provides the point-to-point trend results for each collocated MIDAS-AERONET sites. It should be mentioned
348 that among the revealed stations, few indicate dust particles as the predominant aerosol type. Based on Logothetis et al. (2020),
349 the station of Solar Village, Arabian Peninsula, is primarily a “dusty” site revealing significantly high percentages of coarse
350 absorbing particles. Across this station, the trends between AERONET cAOD (0.0126 yr^{-1}) and MIDAS DOD (0.0107 yr^{-1})
351 are in good agreement in terms of magnitude, but both are non-significant at the 95% confidence level. Similar findings are
352 also observed in the “dusty” site of Tamanrasset, Algeria, showing increasing cAOD and DOD trends of 0.0062 yr^{-1} and
353 0.0044 yr^{-1} , respectively. One of the advantages of MIDAS is that it provides the dust aerosols burden information in
354 downwind regions of the planet. For instance, most of the stations located in South Europe receive dust particles transported
355 towards the Mediterranean from Sahara and Middle East deserts, encompassing identical trend signs (Fig. 4a). Moreover, there
356 are many downwind regions across different regions of the globe with similar trends magnitude such as Ispra, Italy (cAOD=
357 -0.0013 yr^{-1} , DOD= -0.0015 yr^{-1}), Kanpur, India (cAOD= -0.0027 yr^{-1} , DOD= -0.0029 yr^{-1}), SERC (cAOD= -0.0023 yr^{-1} ,
358 DOD= -0.0020 yr^{-1}) in US, Shirahama, Japan (cAOD= -0.0020 yr^{-1} , DOD= -0.0012 yr^{-1}), and XiangHe, China (cAOD=
359 -0.0028 yr^{-1} , DOD= -0.0018 yr^{-1}).
360

361 3.1.4 Filtering vs. non-filtering trends

362 The third sensitivity analysis of this section concerns the calculation of temporal trends using filtered (Fig. 2) and non-
363 filtered (Fig. 5) data at fine spatial resolution. Here, the AOD/DOD trends are calculated by applying two consecutive temporal
364 filters (Sect. 2.3). More specifically, the two applied temporal filters include the: 1) the calculation of the monthly averages
365 when at least 6 days are available and 2) the trend calculation only in grid cells with higher than 60 available months (5 years).
366 The total number of grid points for trend calculation increases when the above two temporal filters are not applied. Overall,
367 months with more than one daily measurement are retained for trend analysis, increasing the total data availability of the entire
368 global grid from 36% (filtered) to 83% (non-filtered).
369

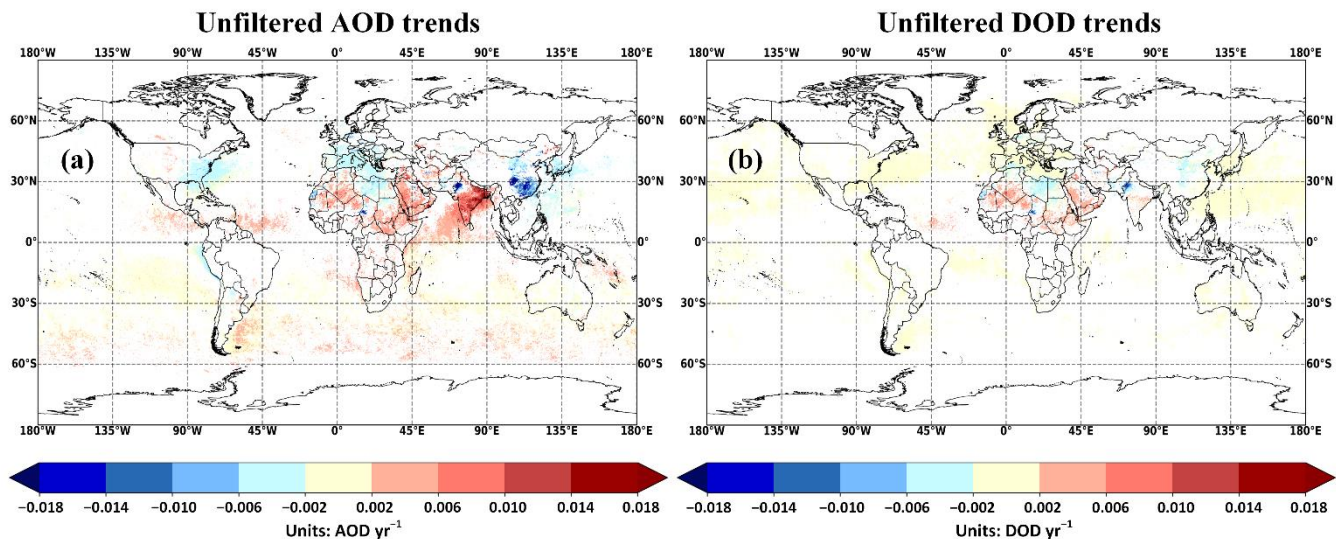

Figure 5: Global maps of unfiltered temporal trends (statistically significant at 95% confidence level), at $0.1^\circ \times 0.1^\circ$ spatial resolution, calculated from the deseasonalized geometric (a) AOD and (b) DOD monthly values during 2003 – 2017.

According to Eq. (3), σ_ω (Fig. S5) and the statistical significance (Fig. S6) of the trend are controlled by σ_N , φ (Fig. S7) and n (Fig S3). The differences in data availability between the unfiltered and filtered trend analysis are depicted in Fig. S8. Across the desert areas, the number of filtered months is adequately high and very close to the non-filtered case (Fig. S8). Thus, no trend differences in magnitude and sign are recorded. Over maritime and continental dust affected areas, new statistically significant AOD and DOD trends are represented when the unfiltered data are employed. Firstly, the number of pixels with statistically significant DOD trends has been significantly increased (Fig. 5b) but the majority of the new trends are mainly neutral located over oceanic territories (yellow pixels). New positive DOD tendencies are observed over Tropical Atlantic and India while new negative trends are recorded across Southeast China (Fig. 5b). Secondly, the significant AOD trends grid points are also strongly increased. New decreasing AOD trends are observed over USA, China and Philippine Sea (Fig. 5a). Especially across the region of southeastern China, the number of significant AOD trends has been increased profoundly. In addition, new AOD increasing trends are recorded over Tropical Atlantic, North Pacific (West of Mexico), Arabian Sea and the oceanic area between 30.0°S and 60.0°S . Despite the increase in monthly data availability, trend analysis without temporal filtering may lead to erroneous and not representative results either for AOD or DOD. In order to investigate in detail the last statement, a sensitivity analysis is performed using in total 76 AERONET stations (Fig. S9a). Through the evaluation analysis of MIDAS DOD trends (Sect. 3.1.3), the AERONET stations have been selected based on their data availability. More specifically, only the stations with at least 10 years of data have been retained for further analysis. The total number of sites has been decreased from 76 (here) to 41 due to temporal filtering (see Sect. 3.1.3). Based on Fig. S9b, the unfiltered temporal trends between MIDAS and AERONET documented a profoundly lower linear correlation ($R=0.51$) while

the data points are more sparse. When trends are calculated without any temporal filtering, the total accuracy of the correct trends has been decreased from 80.5% (Fig. 4c) to 73.7% (Fig. S9c).

In the following sections, and considering all three implemented sensitivity analysis, only the geometric-based DOD and AOD trends (Sect. 3.1.1) at fine spatial resolution (Sect. 3.1.2) including the temporal filtering (Sect. 3.1.4) are discussed.

3.2 Seasonal trends

Dust aerosols' burden is subjected to strong intra-annual and interannual variations with different cycles depending on the source or downwind region (Gkikas et al., 2021b). Here, the seasonal DOD tendencies at a global scale (Fig. 6) are calculated based on the methodology proposed by Hsu et al. (2012). The corresponding seasonal AOD trends are depicted in Fig. S10.

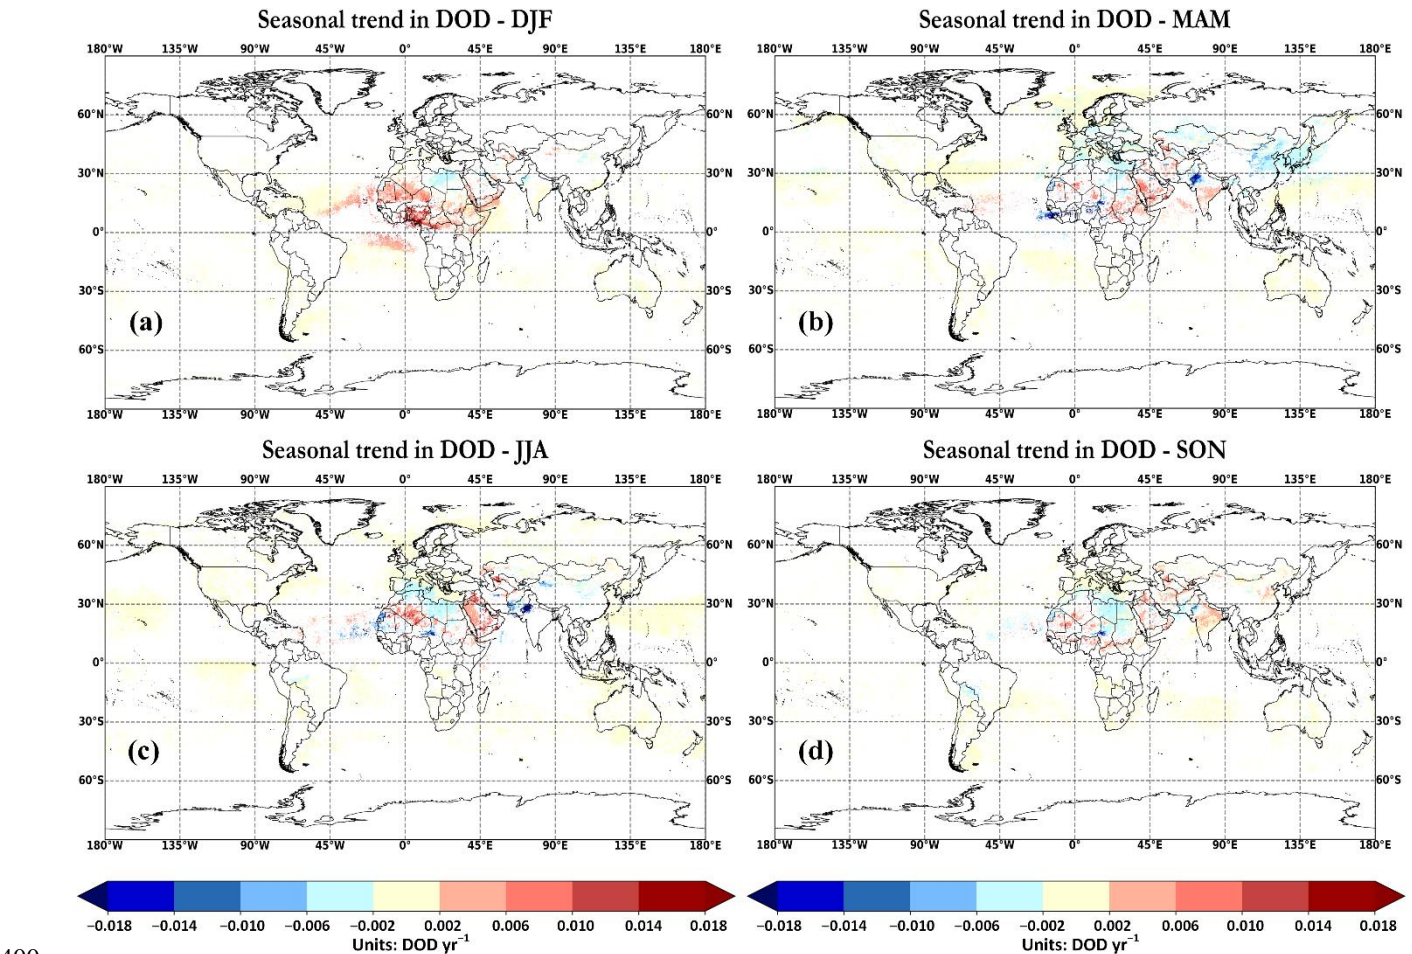

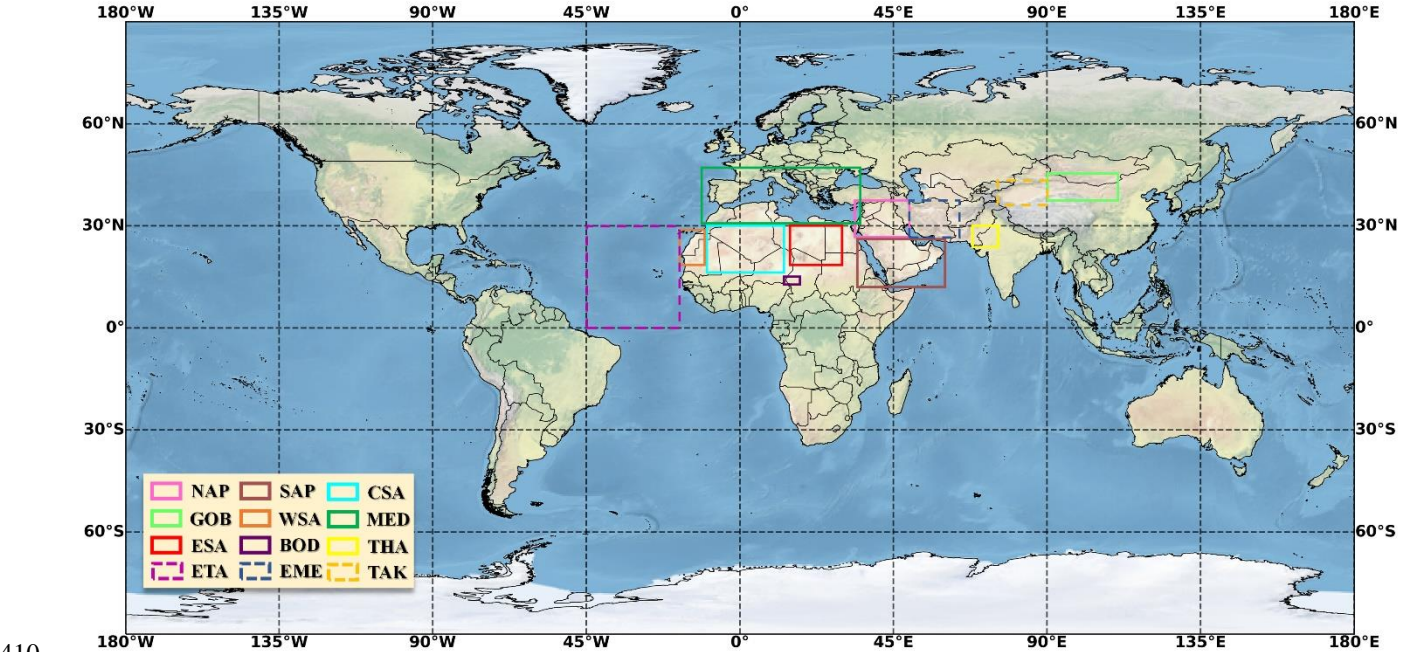

Figure 6: Seasonal geographical distributions of DOD temporal trends at (a) December-January-February (DJF), (b) March-April-May (MAM), (c) June-July-August (JJA) and (d) September-October-November (SON).

403 The detection of the statistical significance of the calculated trends based on Weatherhead et al. (1998) cannot be applied
 404 here due to the 9-month gap among the seasons. Therefore, an alternative approach is followed by calculating the seasonal
 405 trends using a simple linear regression model on the DOD anomalies and identifying the statistically significant trends based
 406 on the two-sided Student's t-test. The null hypothesis of the t-test assumes a non-significant temporal trend under a defined
 407 confidence level (here is 95%). The total number of months for each season is displayed in Fig. S4. Only the grid points with
 408 more than 13 available months (13 from 45 total months) are retained. The performed analysis at global scale and on a seasonal
 409 basis highlights many regions with significant DOD trends (Figs. 2 and 6) which are used to define regional domains (Fig. 7).

410
 411 **Figure 7: Regions of interest for seasonal and regional analysis: North Arabian Peninsula (NAP), South Arabian Peninsula (SAP),**
 412 **Central Sahara (CSA), Gobi Desert (GOB), West Sahara (WSA), Mediterranean (MED), East Sahara (ESA), Bodélé Depression**
 413 **(BOD), Thar Desert (THA), East Tropical Atlantic (ETA), Eastern Middle East (EME) and Taklamakan Desert (TAK). Solid**
 414 **rectangles indicate the regions which are included in the regional analysis (Sect. 3.3) while solid and dashed rectangles are for the**
 415 **seasonal analysis.**

416 The Sahara Desert, hosting some of the most active aeolian natural dust sources of the planet, is a region of great interest
 417 for investigating the intra-seasonal DOD variations. In its central sector, increasing trends are recorded throughout the year
 418 (maximum positive value in JJA) (Table 2). On the contrary, negative seasonal DOD trends appear in the majority regions
 419 across North Africa (Fig. 6). The western and eastern parts of the Sahara Desert present strong declining trends maximized
 420 during boreal summer (Table 2). From spring to autumn, in the Bodélé Depression, substantial decreasing trends are recorded
 421 (Table 2). Over the period 2001–2012, dust emissions in the broader area of the Bodélé Depression were decreased in
 422 summertime, which was attributed to the increased rainfall, caused by the positive trends of the Sahara heat lows (SHL), the
 423 warm phase of Atlantic Multi-decadal Oscillation (AMO) and the decreasing trends in terms of occurrence and intensity of

nocturnal low-level jets' (NLLJ) (Shi et al., 2021). Surface wind speed also affects dust emissions across North Africa (Evan et al., 2016). Surface wind speed and NLLJ are the principal drivers for the interannual variation of dust emissions across Western Sahara, while in summertime dust emissions decreased during 2001–2012 (Shi et al., 2021). The eastern sector of North Africa (North Libya and Egypt) presents moderate negative trends maximized in winter (down to -0.014 yr^{-1}) and spring (down to -0.011 yr^{-1}). In the western sector (i.e. north Algeria and Tunisia) strong significant declining trends are observed in summer (down to -0.035 yr^{-1}) (Fig. 6c). The dust sources residing near the North African coasts are strongly influenced by the surface wind speed, NLLJ, Harmattan surge and the tracks of the Mediterranean depressions (Shi et al., 2021).

Table 2: Seasonal trends over 12 regions of interest. Each column includes: the range of DOD trend (yr^{-1}) and the median DOD trend. Non-available values are shown in blank cells. The domains of the regions are depicted in Fig. 7.

Numerous studies have notified the Saharan transatlantic transport (Peyridieu et al., 2013; Alizadeh-Choozari et al., 2014c; Prospero et al., 2014; Gläser et al., 2015; Fréville et al., 2020; Gkikas et al., 2021b). Across the Gulf of Guinea and mid-Atlantic, relatively high DODs are documented in boreal winter, ranging from 0.1 to 0.2 (up to 0.6) (Gkikas et al., 2021b). According to Fig. 6a, strong positive DOD trends are shown over Gulf of Guinea (up to 0.047 yr^{-1}). In this season, strong northeasterly winds (Harmattan) transport intense loads of Saharan dust towards Nigeria and the Gulf of Guinea (Washington et al., 2006). However, the trend magnitude along the Gulf of Guinea as well as in the northern regions (from Ghana to Cameroon) seems to be unreliable due to the reduced performance of MDF, surface contamination in the received radiances by MODIS and to the co-existence of aerosols and clouds (Gkikas et al., 2021b). In order to investigate the reliability of MIDAS DOD in the above region, the seasonal trend analysis is implemented at the AERONET station of Ilorin, Nigeria. It worths mentioning that this station has not been included in evaluation analysis of Sect. 3.1.3, due to the low number of months ($N=48<60$). However, 32 out of 48 months lie in boreal winter, enabling the application of the methodology during this season. Both datasets represented increasing and statistically significant cAOD (0.011 yr^{-1} , $|\omega/\sigma_\omega|=2.43$) and DOD trends (0.021 yr^{-1} ,

446 $|\omega/\sigma_\omega|=3.74$). As expected, MIDAS revealed higher in magnitude trends than cAOD (approximately 2 times higher). In the
 447 case of AOD (Fig. S10a), identical positive trends as DOD are shown in winter. Interestingly, substantial negative DOD trends
 448 (down to -0.045 yr^{-1}) are recorded during springtime in an area among Guinea, Sierra Leone and North Atlantic Ocean (Fig.
 449 6b), while positive tendencies are documented over Tropical Atlantic Ocean in DJF (Table 2). Over the region extended from
 450 the North Atlantic Ocean to the Eastern Caribbean Sea (Lat: 10.0°N – 18.0°N ; Lon: 70.0°W – 45.0°W), moderate positive trends
 451 are documented predominantly in MAM (up to 0.010 yr^{-1}) and JJA (up to 0.008 yr^{-1}). Dust transport from North Africa along
 452 the Atlantic Ocean reaches the Caribbean Sea, while summer DODs are intertwined with tropical Atlantic cyclone activity.
 453 More specifically, Caribbean DOD during summer is negatively correlated to Atlantic accumulated cyclone energy and
 454 Atlantic Meridional Mode index (Xian et al., 2020). In addition, dust aerosol burden originated from Sahara Desert is directly
 455 related to tropical cyclones (TCS) over Tropical Atlantic Ocean, but their relationship is not unambiguously clarified (Evan et
 456 al., 2006). Based on model simulations, Pan et al. (2018) investigated the role of dust aerosols for the genesis of TCs over
 457 tropical Atlantic basin, by comparison of dust and non-dust model simulations. They revealed that dust amount is directly
 458 related to TCs, revealing a bimodal pattern. More specifically, favorable conditions for TCs formation are documented by
 459 increasing the midlevel moisture and decreasing the vertical wind shear while unfavorable conditions are encompassed by
 460 decreasing the low-level vorticity and potential intensity.

461 Increasing tendencies, throughout the year, appear in the Middle East (Table 2), with few exceptions, particularly in the
 462 northern Arabian Peninsula (Fig. 6). More specifically, the southwestern sector of Oman presents the highest increasing trends
 463 for all seasons (up to 0.026 yr^{-1}). Similarly, high positive trends in MAM (up to 0.015 yr^{-1}) and JJA (up to 0.018 yr^{-1}) are
 464 documented over the western part of Saudi Arabia. Negative tendencies are observed for all seasons at the north of the Oroug
 465 Bani M'aradh Wildfire Sanctuary (South Saudi Arabia) including strongly negative DOD trends in summer (down to -0.020
 466 yr^{-1}) and spring (down to -0.019 yr^{-1}). In the northern part of the Arabian Peninsula, positive trends are detected predominantly
 467 in JJA and SON. Dust activity across the Arabian Peninsula is strongly influenced by the intensity of the northwesterly Shamal
 468 winds, favored by the low precipitation amounts during summer (Yu et al., 2015). The temporally extended drought (Notaro
 469 et al., 2015) along with the cooling of the Tropical Indian Ocean and the Mediterranean Sea temperatures (Yu et al., 2015),
 470 leading to an enhancement of the Shamal winds, could regulate the summer DOD trends across Arabian Peninsula. During
 471 springtime, La Niña events constitute the principal drivers for the dust activity by reducing the rainfall amounts over Rub' al
 472 Khali Desert; one of the most active dust sources across the Arabian Peninsula (Yu et al., 2015). Strong positive trends (up to
 473 0.026 yr^{-1}) are encountered in MAM and JJA over Iraq, while significant increasing trends are recorded for all seasons across
 474 the eastern Iran, with the most evident ones in spring (up to 0.020 yr^{-1}). However, a hotspot of strong declining trends exists
 475 in southeastern area of Iran (34.5°N , 54.5°E) with the most negative values in JJA (down to -0.029 yr^{-1}) and SON (down to
 476 -0.025 yr^{-1}). Moderate negative DOD trends are documented during the summertime (down to -0.01 yr^{-1}) across the Alboran
 477 Sea (western Mediterranean). The dust aerosol burden has also been decreased in the eastern part of Mediterranean Sea during
 478 spring (down to -0.006 yr^{-1} , from Libya and Egyptian coasts to Aegean Sea) and autumn (down to -0.005 yr^{-1} , across the
 479 Gulf of Sidra).

480 Statistically significant positive DOD trends are detected across the intersection of Kazakhstan, Uzbekistan and
481 Turkmenistan, in the northeastern Caspian Sea shore. At all seasons, the DOD trends exceed 0.011 yr^{-1} while the maximum
482 trends are recorded in summer (up to 0.035 yr^{-1}) and spring (up to 0.019 yr^{-1}). These findings substantiate the positive decadal
483 DOD trends ($\sim 0.18 \text{ decade}^{-1}$) of Voss and Evan (2020) and could be attributed to the amount of drawdown ($\sim -6.72 \text{ cm yr}^{-1}$)
484 in the Caspian Sea level during 1996–2015 (Chen et al., 2017). Central, South and East Asia constitute another regions of
485 interest in which robust DOD trends are encountered (Fig. 6). The maximum negative values are depicted over the Thar Desert
486 in JJA and MAM (Table 2). It must be highlighted that the maximum decreasing trends are detected during the high-dust
487 season in the Thar Desert (Proestakis et al., 2018). The reduction of dust load during the pre-monsoon (MAM) could be
488 attributed to the increase of the rainfall and soil moisture levels, acting in favor of wet dust deposition as well as decreasing
489 the dust erosion (Pandey et al., 2017; Jin and Wang, 2018; Lakshmi et al., 2019). Moreover, reductions in dust emissions are
490 recorded during summertime, which are strongly linked to soil moisture and wind speed (Shi et al., 2021). In Northwest China
491 (Central Asia) lies the Taklamakan Desert, where non-significant annual trends are documented (Fig. 2). However, significant
492 seasonally negative DOD trends are observed (Fig. 6) particularly in summertime (Table 2). Additionally, over the Gobi Desert
493 and East Asia strongly negative DOD tendencies are documented mainly in spring (Fig. 6b), when the dust activity peaks
494 (Proestakis et al., 2018). The negative DOD trends across the Gobi Desert could be attributed to reduced dust emissions, caused
495 by the decrease of surface wind speed which has been recorded between 2010–2016 (Guo et al., 2019).

496 3.3 Regional trends

497 The regional DOD and AOD trends are calculated for 9 specific regions of interest (Table 3 and Fig. 7 solid rectangles)
498 as well as for the whole globe (GLB) and separately over land (GLB-L) and ocean (GLB-O) (Sect. 3.3.1). The full names of
499 each region as well as the calculated regional DOD trends and their uncertainties are included in Table 3. The comparisons
500 among the geometric vs. arithmetic aggregation method and coarse vs. fine spatial resolution are also investigated for the
501 regional DOD (Fig. 8a) and AOD (Fig. 8b) trends. On a regional basis, the temporal trends between the two spatial resolutions
502 are in very good agreement, corroborating de Meij et al. (2012). Since the statistical significance of the trends is strongly
503 influenced by the number of years and the study period, the regional DOD trends are also computed for different time periods
504 considering the systematic change of time period (number of years) and initial year (Fig. 9).

Thar Desert	THA	-5.3	1.9	2.8*

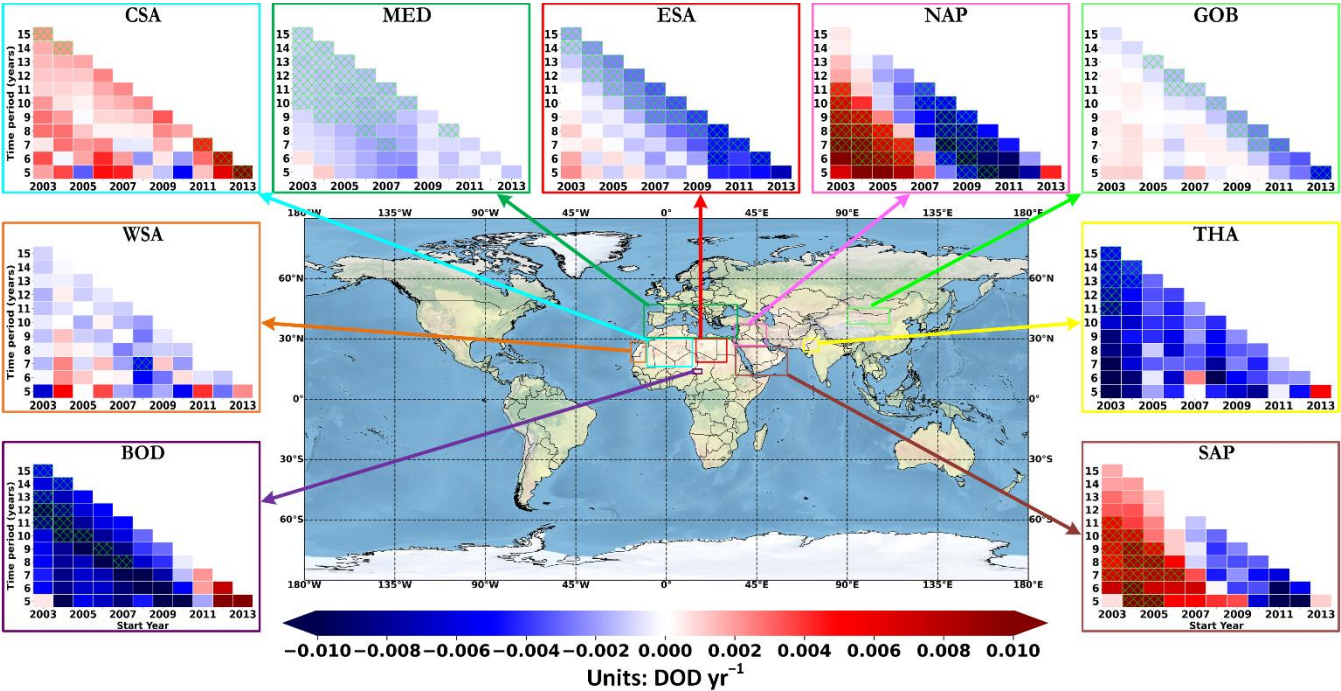

523

524

525

Figure 8: Bar-plots indicating the (a) DOD and (b) AOD regional temporal trends. The hatched bars represent regions with the significant trends ($|\omega/\sigma_\omega| > 2.0$). The error bars denote the uncertainty of the trends based on Eq. (3) (Sect. 2.3).

526 The explanation of the temporal evolution of calculated trends shown in Fig. 9 is presented in the next section for individual
 527 regions.

528
 529 **Figure 9: Regional DOD trends at different time intervals, with at least 5-year time series. The acronyms full names are documented**
 530 **in Table 3. YY' axis shows the number of trends included in the analysis, while XX' the starting year. The hatched pixels represent**
 531 **regions with the significant trends ($|\omega/\sigma_\omega| > 2.0$).**

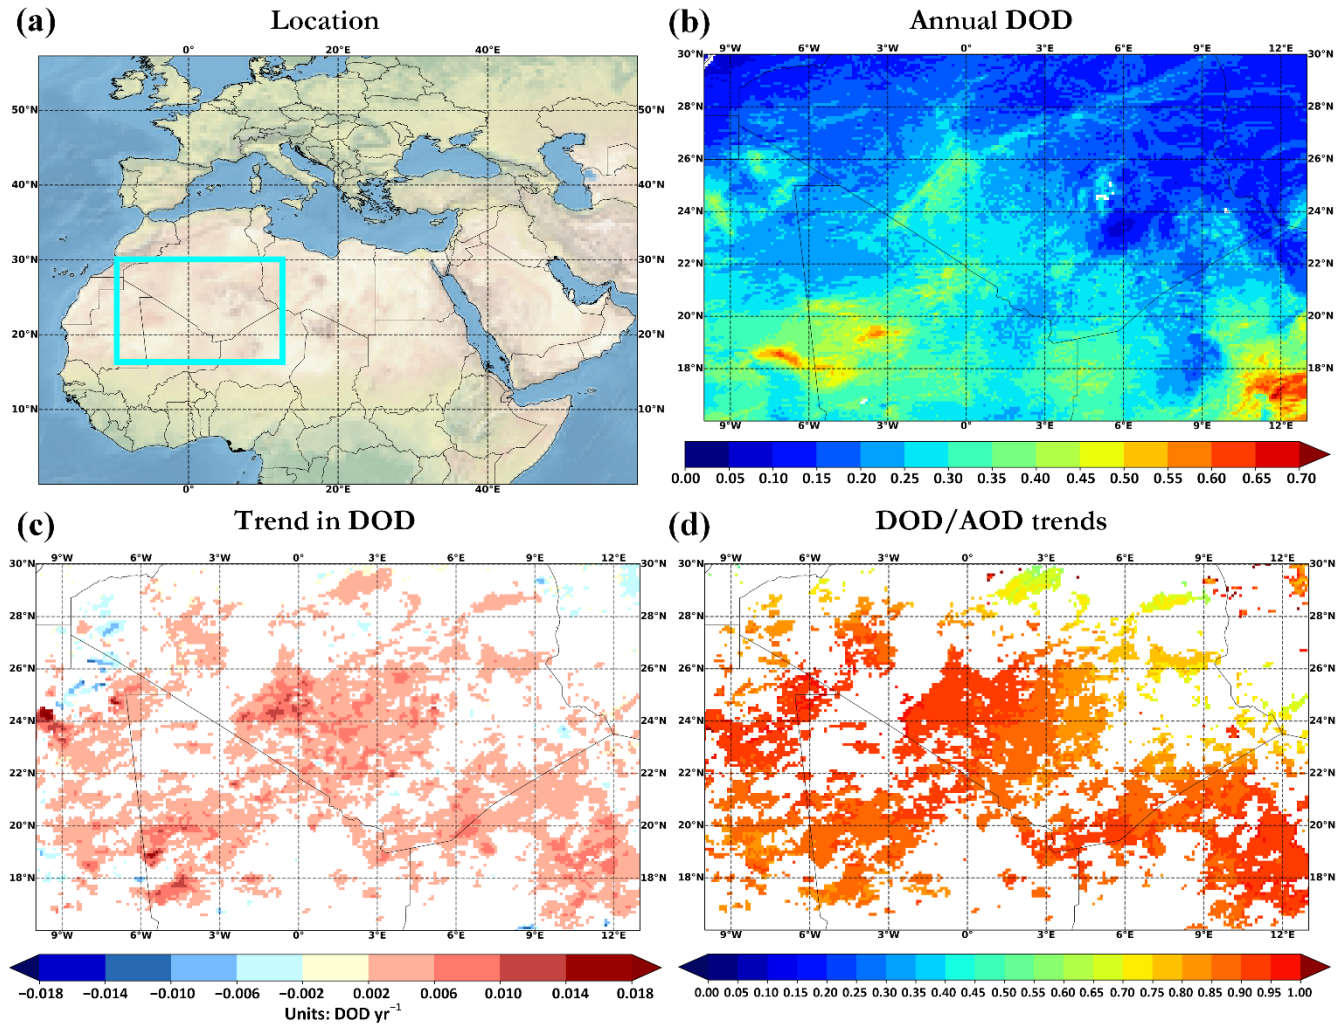

532 **3.3.1 Global land and ocean**

533 Small global DOD trends are recorded during the study period both over land and ocean (Table 3). However,
 534 distinguishable DOD trends are detected at specific regions. Prior studies have focused on satellite-based measurements
 535 detecting statistically significant AOD trends at global scale. Over oceanic areas, AOD trends based on MODIS Collection 6.0
 536 are reported to be equal to 0.0050 decade⁻¹ and 0.0020 decade⁻¹ during 2000–2009 and 2000–2015, respectively (Alfaro-
 537 Contreras et al., 2017). SeaWiFS AOD retrievals recorded higher annual positive significant trends over ocean (0.00080 yr⁻¹)
 538 for a 13-year period (1998–2010) (Hsu et al., 2012). Recently, significant positive tendencies are documented for GLB
 539 (0.00066 yr⁻¹) using L3 Collection 6.1 MODIS/Terra measurements spanning from 2001 and 2016 (Che et al., 2019). In this
 540 study, significant AOD trends of 0.00052 yr⁻¹ and 0.00051 yr⁻¹ are revealed over GLB-O and GLB respectively (Fig. 8b),
 541 using geometric means at fine spatial resolution. The differences in trends magnitude among the studies are attributed to the
 542 different datasets, aggregation methods and temporal availability.

543 **3.3.2 North Africa**

544 Across North Africa, four sectors have been defined based on the sign of the DOD trends (see Figure 7) The first one
545 consists of Central Sahara (CSA) where increasing DOD trends are mainly recorded (up to 0.023 yr^{-1}) (Fig. 10c). Voss and
546 Evan (2020) also reported similar DOD trends, in terms of sign and magnitude, based on MODIS/Aqua dataset over the period
547 2003–2018. At regional scale, positive significant DOD trends of 0.0021 yr^{-1} determining those of AOD as expected (regional
548 DOD to AOD trend ratio= 0.84) due to the predominance of mineral particles in the area among other aerosol species (Fig.
549 10d). During different time frames, the sign of DOD trends remains mainly positive (Fig. 9), with intense (from 0.0044 to
550 0.0095 yr^{-1}) and significant results within the 2011– onward periods. Nevertheless, the time window is very short to infer the
551 amplitude of the calculated trends.

Central Sahara - CSA

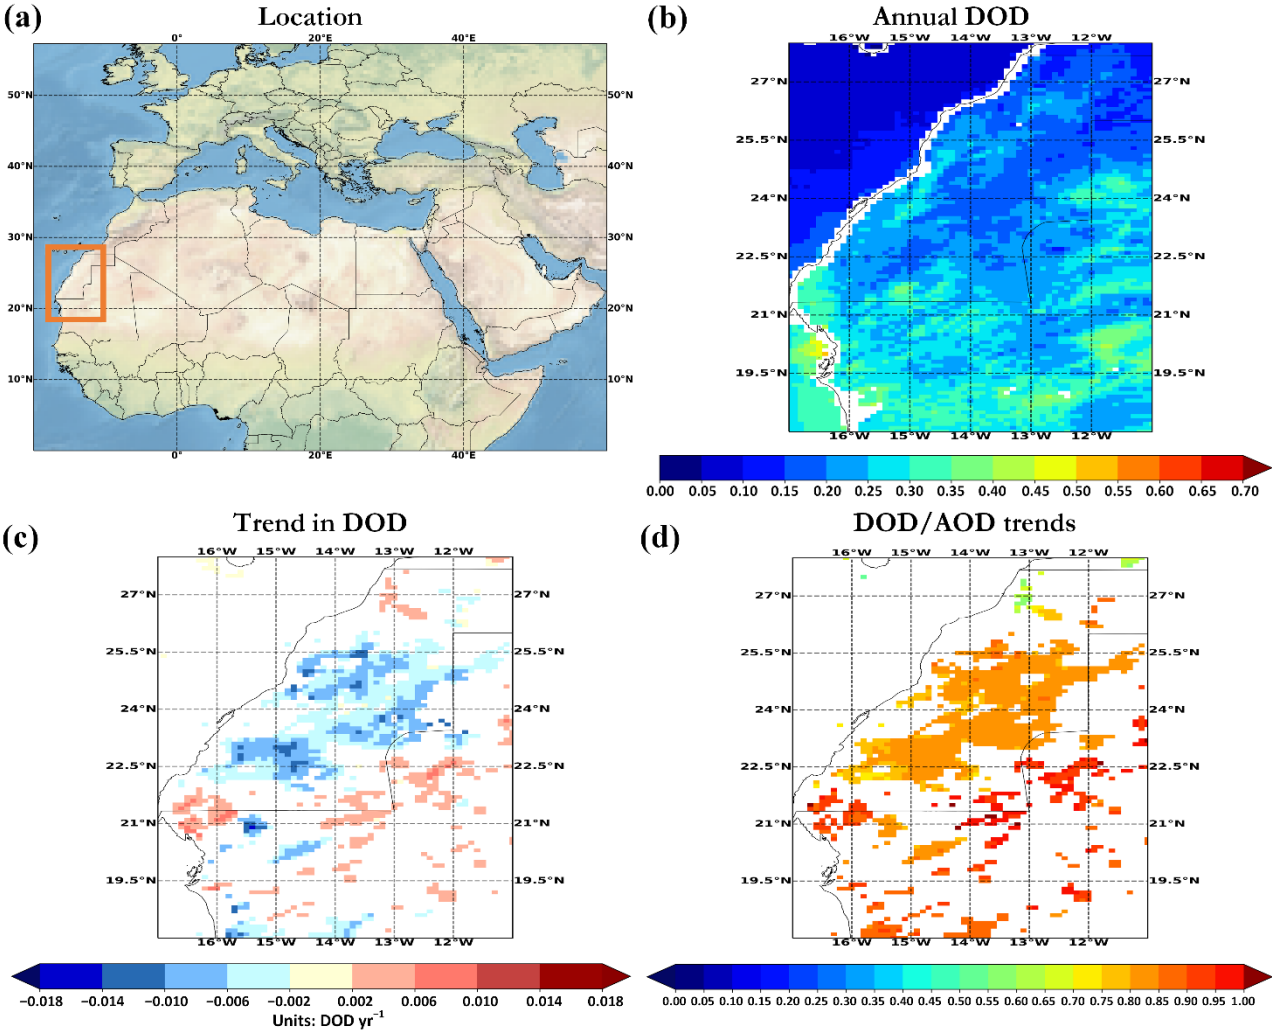

552

553 **Figure 10: (a) geographical boundaries, (b) annual DOD, (c) DOD geometric trends and (d) DOD to AOD trends ratio, for the**
554 **Central Sahara.**

555 In the westernmost section of the Sahara Desert (WSA), in the majority of grid-cells (~73%) decreasing DOD tendencies
556 are recorded (down to -0.015 yr^{-1}) whereas positive trends (up to 0.009 yr^{-1}) are evident at scattered pixels (~27%) within the
557 domain (Fig. 11c). Overall, the total load (Fig. 8a) as well as the dust burden (Fig. 8b) have been decreased during the study
558 period, but the magnitude of this reduction is relatively low and not statistically significant. This behavior is consistent
559 regardless the spatial resolution or the approach for the calculation of regional values (i.e. arithmetic or geometric mean) (Figs.
560 8a and 8b). The same DOD trend pattern is also reflected using different time periods (Fig. 9).

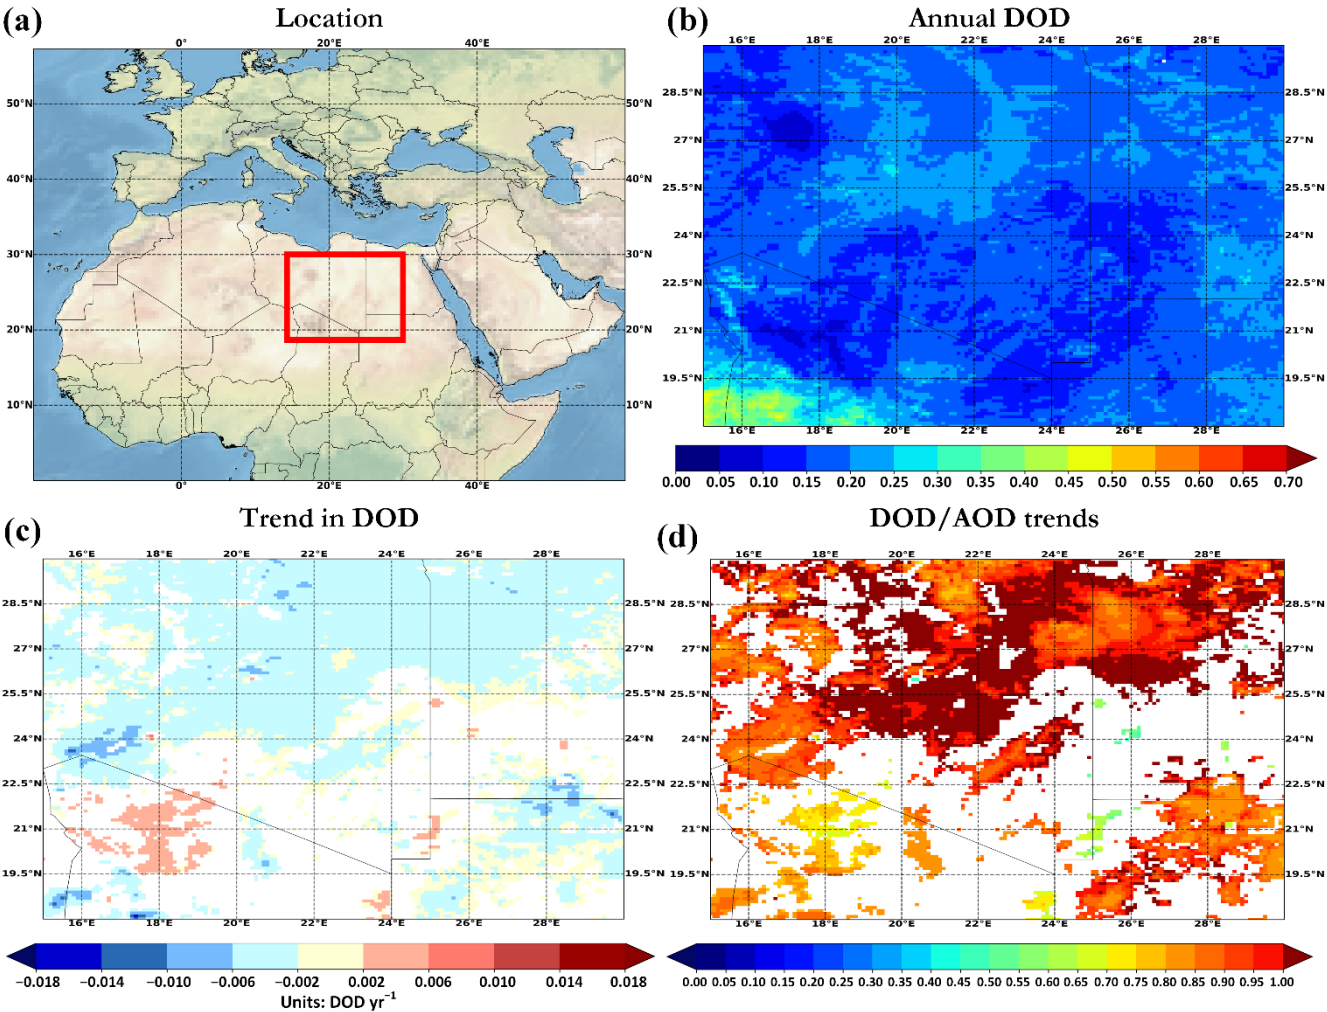

West Sahara - WSA

561
562 **Figure 11: Same as Fig. 10, but for the Western Sahara.**

563 In the eastern sector of the Sahara Desert (ESA), statistically significant negative DOD trends (down to -0.023 yr^{-1}) (Fig.
 564 12c) are revealed as well as both for regional DOD (Fig. 8a) and AOD (Fig. 8b) trend thus indicating the predominant
 565 contribution of mineral particles to the total aerosol load. Reduction of the dust burden has also been recorded from
 566 MODIS/Terra dataset according to Voss and Evan (2020). Dust particles affect potentially total AOD across ESA indicating
 567 a regional DOD to AOD trend ratio of 1.06. Over the dust-affected areas of the planet, the DOD to AOD trends ratio range
 568 from negative (different trend sign) to higher than unity values. Since the dust burden modulate the total AOD over ‘dusty’
 569 regions, the ratio between DOD and AOD is expected around unity. Higher ratios than unity are expected as the non-dust AOD
 570 signal decreases or increases and the DOD signal shows a reciprocal pattern. According to Fig. 9, two significant outcomes
 571 can be extracted in ESA. The magnitude, in absolute terms, of the decreasing DOD trends increases (down to -0.0054 yr^{-1} ;
 572 2012–2017) and the statistical significance is achieved for shorter time periods for increasing starting years.

East Sahara - ESA

573

574 **Figure 12: Same as Fig. 10, but for the Eastern Sahara.**

575 Within the study period, the regional dust load decreases (-0.0055 yr^{-1}) in the Bodélé Depression (BOD) consisting the
576 most active aeolian dust source of the planet (Prospero et al., 2002; Washington et al., 2006; Todd et al., 2007; Gkikas et al.,
577 2021b). DOD trends range from -0.021 yr^{-1} to -0.003 yr^{-1} (Fig. 13c), corroborating the findings of the Voss and Evan (2020).
578 For starting years between 2003–2010 the dust aerosol burden decreases (Fig. 9), with the most negative trend found during
579 2007–2014 (-0.015 yr^{-1}). As the starting year increases and the time length decreases, the magnitude of DOD trends become
580 weaker. More specifically, the sign of DOD trends is shifted using 2011–2013 as starting years, but the results are not
581 statistically significant. The latter indicates that DOD over the most active dust source of the planet becomes more intense
582 during the last years. The aerosols' burden over the Sahara Desert is modulated by meteorological parameters affecting the
583 dust emissions such as precipitation (Pozzer et al., 2015) and wind speed (Che et al., 2019). Based on model simulations,
584 Pozzer et al. (2015) confirmed that positive AOD trends across Sahara Desert are linked to negative precipitation trends during
585 2001–2010. Decreasing precipitation levels reduces dust deposition and favors dust transport, leading to an increase in dust
586 amounts. In addition, Che et al. (2019) reported that wind speed is the most critical feature for explaining the variance of AOD
587 (by 29.8%). During the high dust seasons, the interannual variation of dust emissions is affected by wind speed and the NLLJ
588 (in the southern Sahara dust sources) as well as by the Harmattan surge and Mediterranean depressions (in the northern Sahara
589 dust sources) (Shi et al., 2021).

Bodélé Depression - BOD

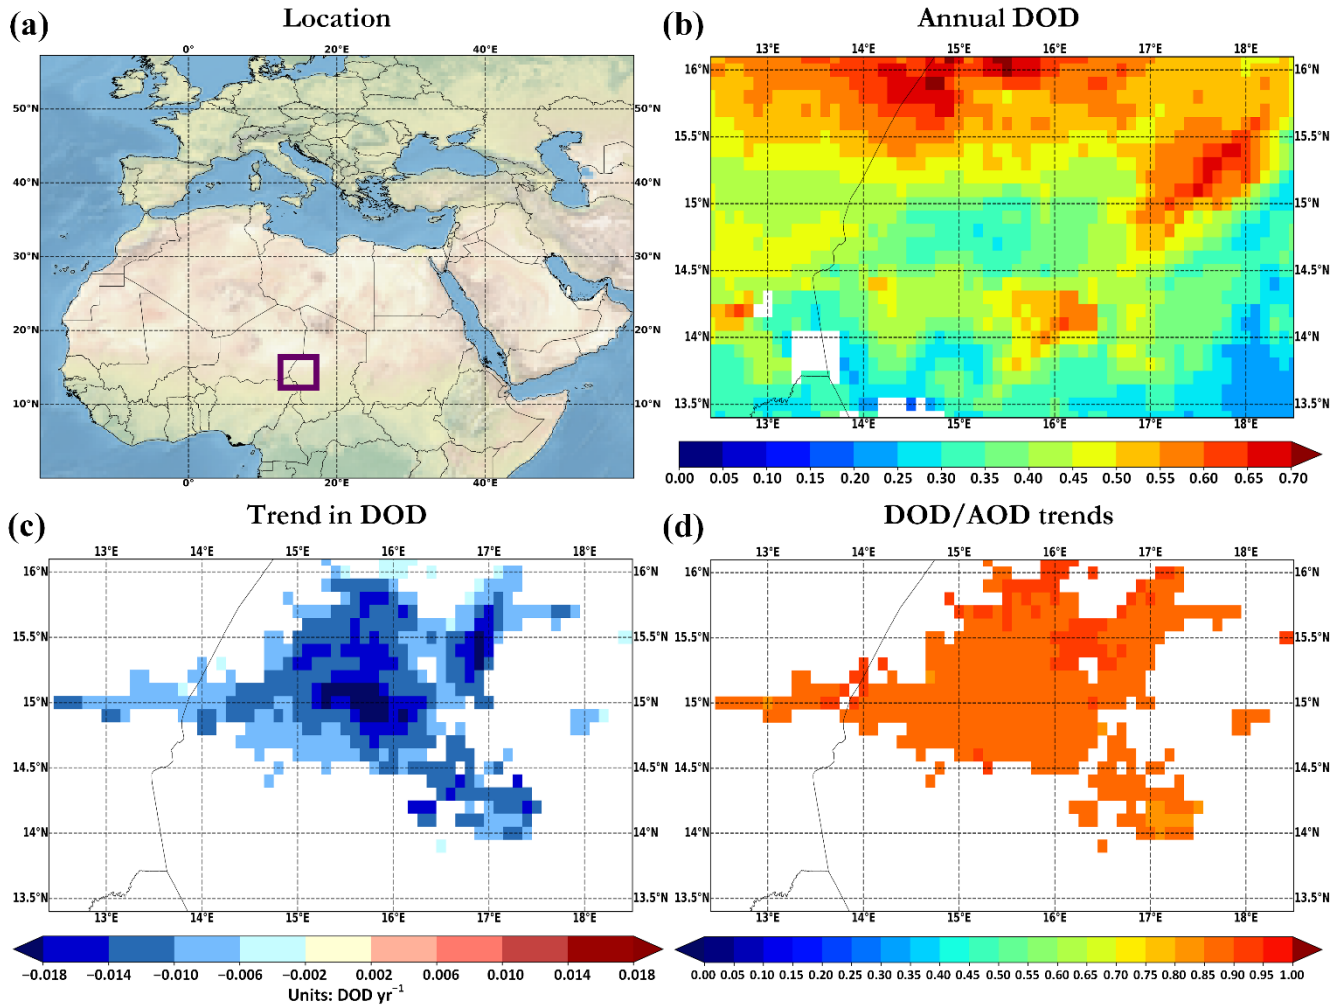

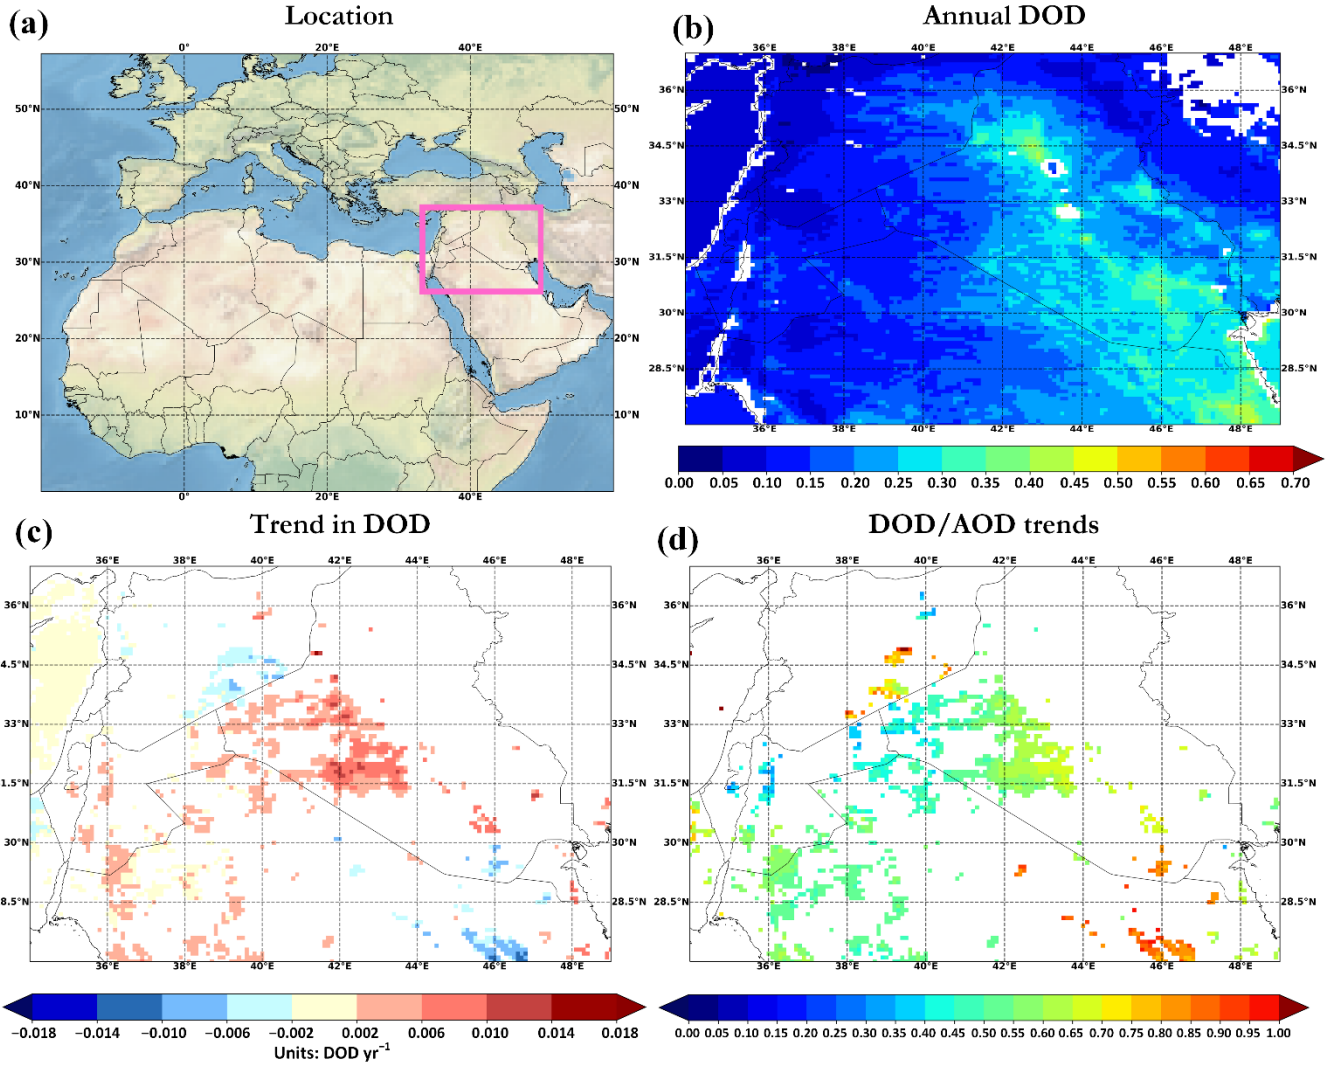

Figure 13: Same as Fig. 10, but for the Bodélé Depression.

3.3.3 Arabian Peninsula

The DOD tendencies over the Arabian Peninsula are presented separately for the northern (NAP) and the southern (SAP; including Jordan, Iraq and Syria) sectors. In both regions, positive trends (non-significant, Fig. 8a) are computed which are stronger in the southern parts of the Arabian Peninsula.

North Arabian Peninsula - NAP

596

597 **Figure 14: Same as Fig. 10, but for the North Arabian Peninsula.**

598

599

600

601

602

603

604

605

Across Arabian Peninsula, the sign of the trend provides a bimodal pattern, revealing strong positive trends for time frames up to 2013 and followed by negative trends onwards (Fig. 9). Our findings are consistent with the revealed regime shift regarding dust activity in the Arabian Peninsula, as discussed in Notaro et al. (2015). The increased dust activity is also reflected in MIDAS DODs between 2008 and 2012, recording increased and stable annual DOD values (~ 0.2) compared to the previous 2003–2007 period DOD values (~ 0.15). Due to these sudden changes of dust amounts tendencies (from positive to negative), the regional DOD trends revealed non-significant within the entire study period (Fig. 8a). Klingmüller et al. (2016) documented increasing AOD trends during 2001–2012 followed by declining tendencies onwards, in agreement with our findings (Fig. 9). The predominant role of mineral particles on the total aerosol load across the Arabian Peninsula, is also

South Arabian Peninsula - SAP

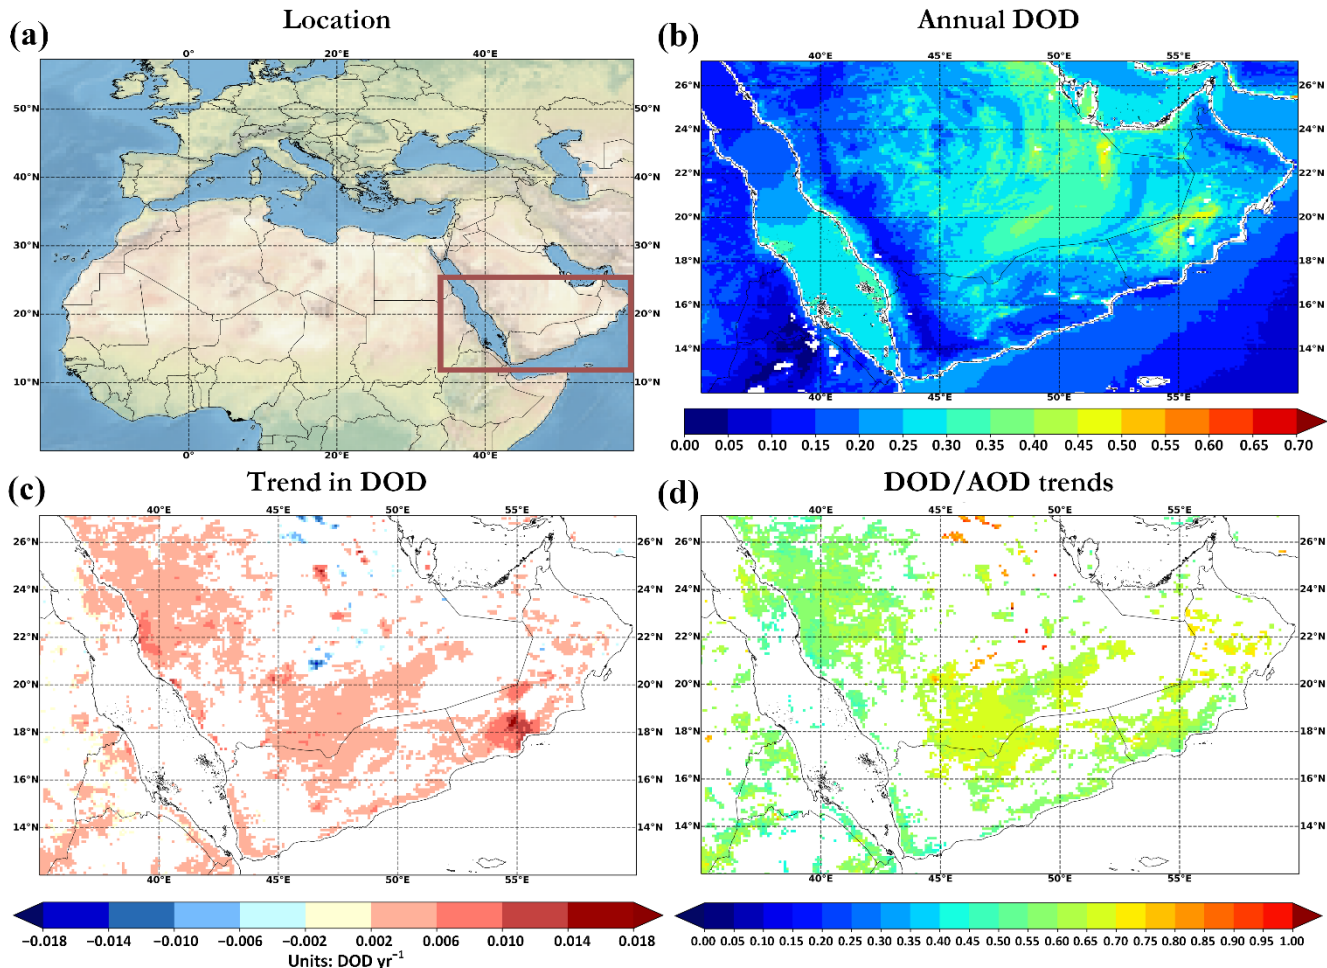

Figure 15: Same as Fig. 10, but for the South Arabian Peninsula.

In the last few decades, compelling inter-annual dust activity is documented in the Arabian Peninsula (Notaro et al., 2015). Numerous studies examined the temporal variability of aerosol loads in the Middle East, showing strong ascending tendencies (de Meij et al., 2012; Hsu et al., 2012; Yoon et al., 2014; Pozzer et al., 2015; Klingmüller et al., 2016; Che et al., 2019; Wei et al., 2019a). Klingmüller et al. (2016) revealed that the positive AOD trends in Middle East are associated with decreasing trends of Ångström exponent (AE) and fine mode fraction (FMF) indicating a shift towards a regime with stronger presence of coarse particles. These findings are in agreement with the increasing DOD trends documented in this study during the same study period (Fig. 9). Moreover, Klingmüller et al. (2016) implemented a multivariate linear model for annual AOD in order

618 to identify the linkage of AOD trends with critical parameters such as the precipitation, the surface soil moisture and the surface
619 wind speed. Soil moisture is the major controlling parameter in Saudi Arabia and Iraq whereas precipitation dominates in Iran.
620 For all regions, the addition of surface wind speed as independent parameter upgraded the model performance. Moreover, Che
621 et al. (2019) also used a multiple linear regression model to investigate the relationship of AOD with specific meteorological
622 parameters. The most appropriate ones, in terms of statistical significance, are chosen to enhance the model performance.
623 Across Middle East, the major controlling meteorological parameter for AOD variance is the sea level pressure (60.9% of total
624 AOD explained variation) and the wind speed, highlighting the large impact of synoptic systems on dust burden over the area.
625

626 **3.3.4 Mediterranean**

627 The Mediterranean (MED) basin is a region of great concern due to high inter-annual variability of aerosol loadings and
628 types (Floutsi et al., 2016). In this study, MED presents significant DOD trends ranging from -0.009 yr^{-1} to 0.006 yr^{-1} (Fig.
629 16c). The regional analysis documents strong declining significant DOD (Fig. 8a) and AOD (Fig. 8b) tendencies across the
630 MED basin. Negative DOD trends are also revealed during different sub-periods (Fig. 9). The DOD to AOD trends ratio shows
631 a latitudinal reduction moving from northern African coasts to the northern parts of the Mediterranean (Fig. 16d). Higher ratio
632 values are documented in South Mediterranean-North African coast region (0.3-1.94, median = 0.71) (Lat: 30.0–38.0 °N; Lon:
633 6.0 °W–30.0 °E) compared to North Mediterranean (0.21-0.91, median = 0.45) (Lat: 38.0–45.0 °N; Lon: 1.0 °W–27.0 °E). Dust
634 particles originated from North African and Middle East deserts driven by low pressure systems (cyclones) can be transported
635 towards MED (Gkikas et al., 2015), providing relatively high AOD values at the southern parts. Mineral particles are recorded
636 mainly in summer, spring and winter in Western, Central and East MED, respectively (Floutsi et al., 2016; Gkikas et al., 2013;
637 2016; 2021b). Across the north sector of MED, lower AOD values are associated with higher FMF values due to the prevailing
638 anthropogenic fine aerosols (Floutsi et al., 2016). The latter could also be observed from the negligible DOD trends there (Fig.
639 16c).

Mediterranean - MED

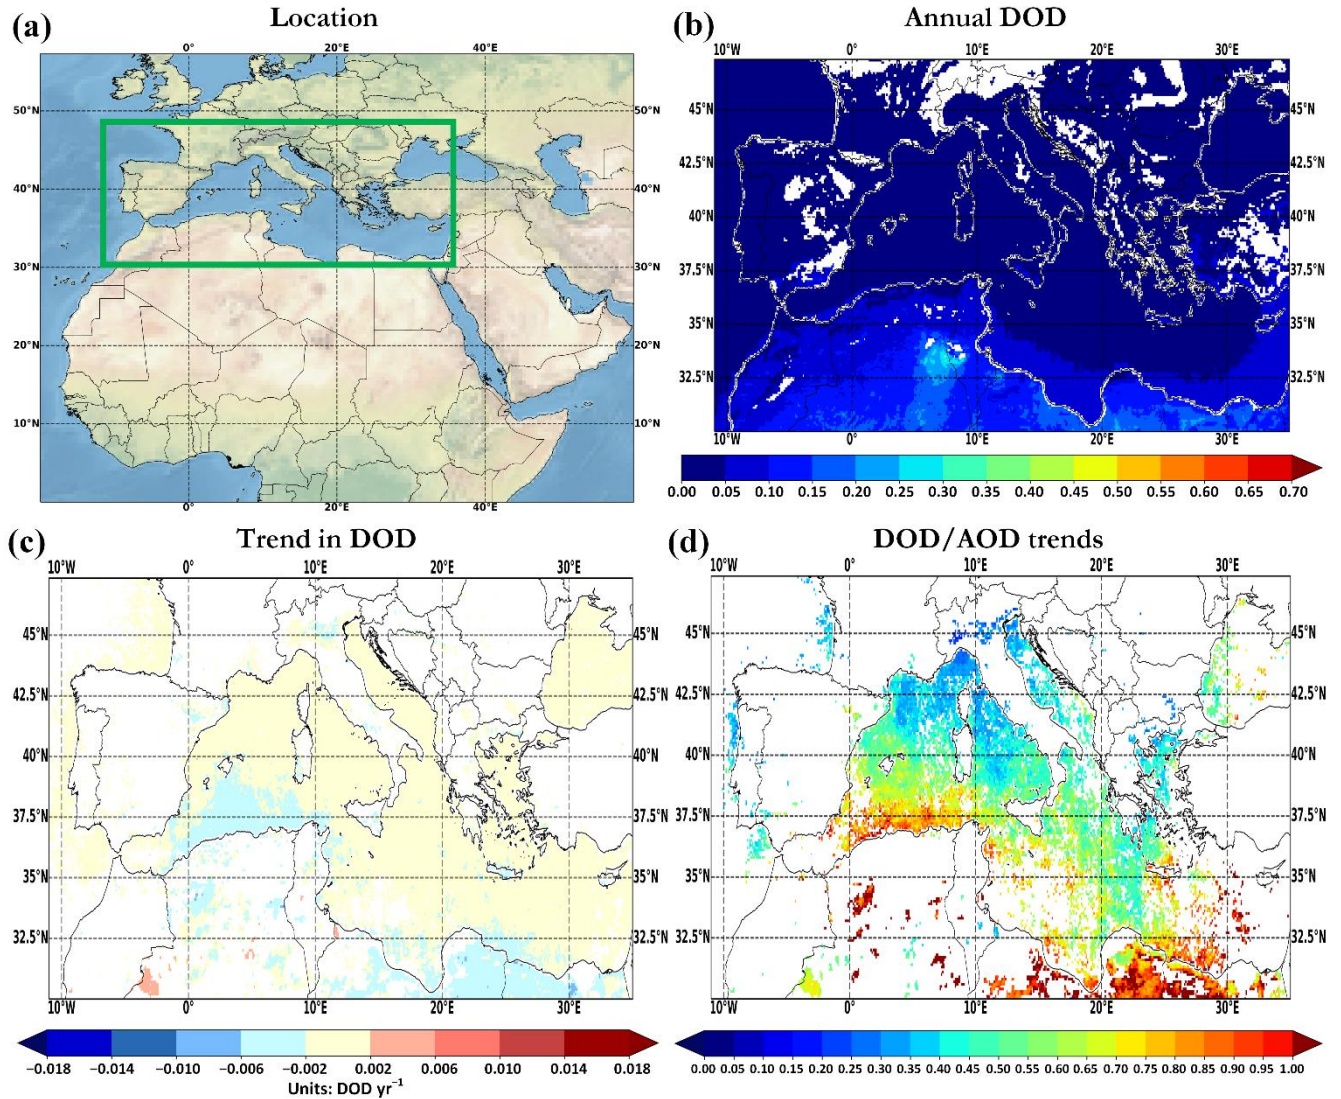

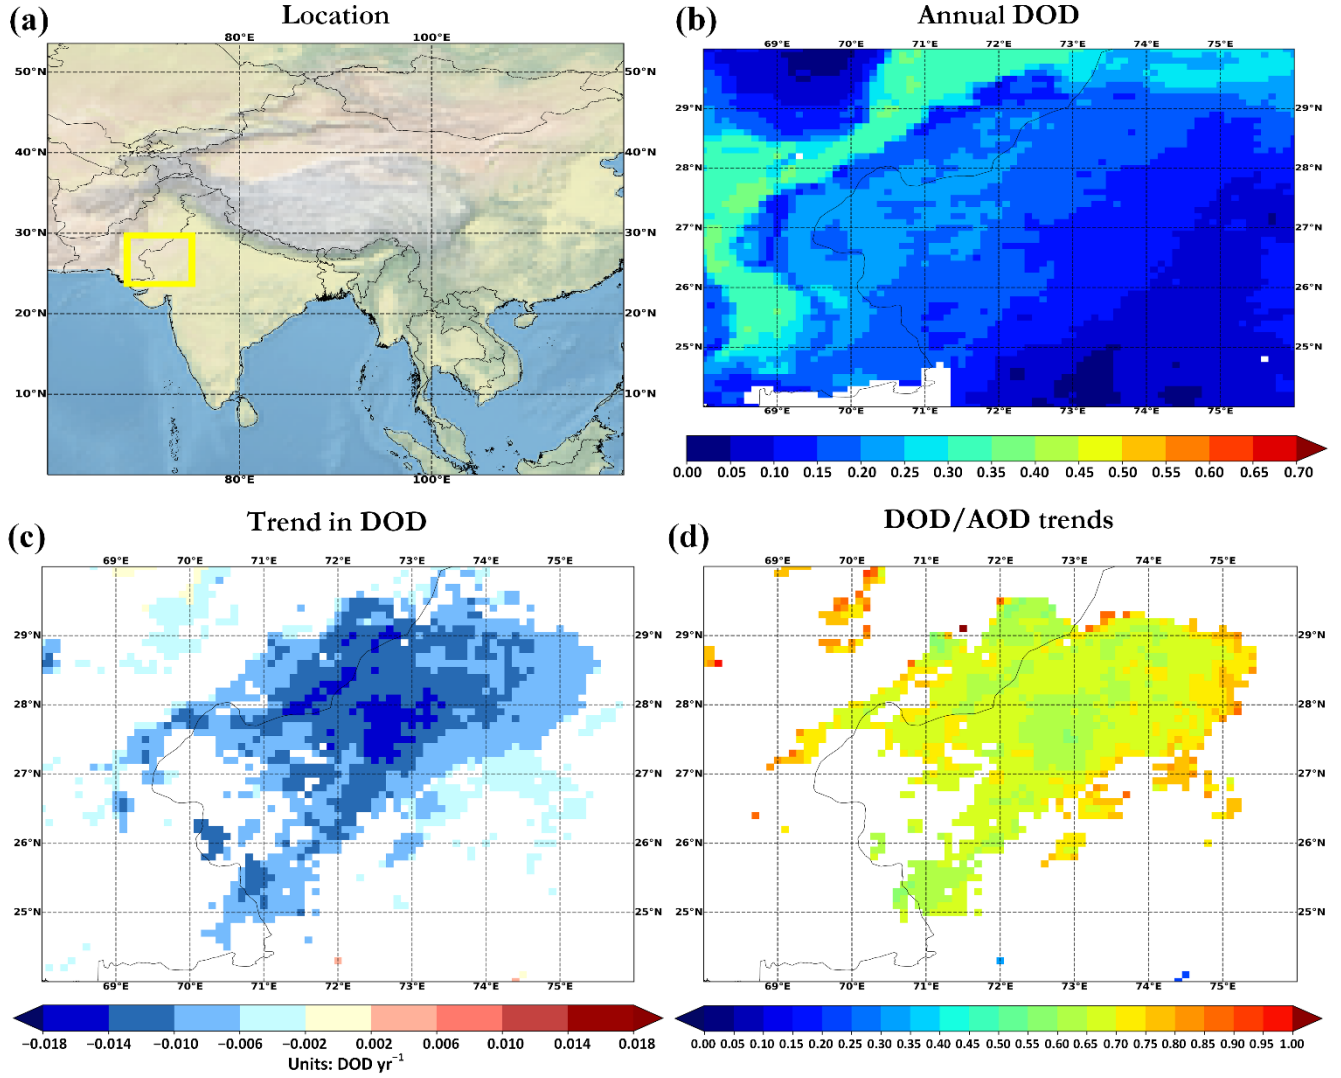

Figure 16: Same as Fig. 10, but for the Mediterranean Basin.

Earlier studies investigated the temporal AOD variability in the broader Mediterranean basin, reporting declining tendencies for the last two decades (Papadimas et al., 2008; de Meij et al., 2012; Hsu et al., 2012; Yoon et al., 2014; Pozzer et al., 2015; Floutsi et al., 2016; Che et al., 2019). Across this region, Floutsi et al. (2016) reported significant decreasing AOD trends of -0.0030 yr^{-1} over the period 2002–2014. Additionally, Nabat et al, 2013, reported decreasing DOD trends (-0.0045 yr^{-1}) across northern Africa. Both studies corroborate with the findings of this study where the overwhelming majority DOD trends are primarily slightly negative (Fig. 16c).

648 **3.3.5 Thar and Gobi Deserts**

649 Across the western part of Indo-Gangetic Plain, in the northwest area of the Indian Subcontinent, the Thar Desert (THA)
650 is situated. THA region depicts significant decreasing DOD trends (down to -0.017 yr^{-1}) (Fig. 17c) modulating the
651 corresponding declining AOD tendencies as indicated by the relatively high DOD/AOD trends ratio (0.67; Fig. 17d). The
652 statistical significance of DOD trends, which are always negative regardless the sub-period, is strongly affected by the starting
653 year as well as the length of the time interval in which the tendencies are computed (Fig. 9). More specifically, negative and
654 not statistically significant DOD trends are observed for all time periods beginning from 2005. During the last two decades,
655 strong negative temporal trends are recorded for OMI ultraviolet aerosol index (Hammer et al., 2018) along with AOD (Che
656 et al., 2019) and DOD (Voss and Evan, 2020) across THA. The reduction of dust abundance over THA is mainly attributed to
657 the increase of the rainfall and soil moisture enhancing wet dust deposition and reducing dust erosion during pre-monsoon
658 (Pandey et al., 2017; Jin and Wang, 2018).

Thar Desert - THA

659

660 **Figure 17: Same as Fig. 10, but for the Thar Desert.**

661

662

663

664

665

666

667

The Gobi Desert (GOB) resides between the north part of China and the southern sector of Mongolia (East Asia). In this region, statistically significant DOD trends, ranging from -0.011 yr^{-1} to 0.004 yr^{-1} , are reported (Fig. 18c), in agreement (both in sign and magnitude) with those reported by Che et al. (2019) and Voss and Evan (2020) for AOD and DOD, respectively. At a regional level, slightly negative DOD (-0.00071 yr^{-1}) and AOD (-0.0010 yr^{-1}) trends, and statistically significant at 90% confidence level ($|\omega/\sigma_\omega| > 1.65$), are computed (Fig. 8). Nevertheless, for time periods onwards 2005, the DOD trends are statistically significant at 95% confidence level (Fig. 9). These temporal DOD trends corroborate with Filonchyk et al. (2019), who computed AOD trends equal to $-0.004 \text{ decade}^{-1}$ and $-0.002 \text{ decade}^{-1}$ for MODIS/Terra and MISR measurements,

Gobi Desert - GOB

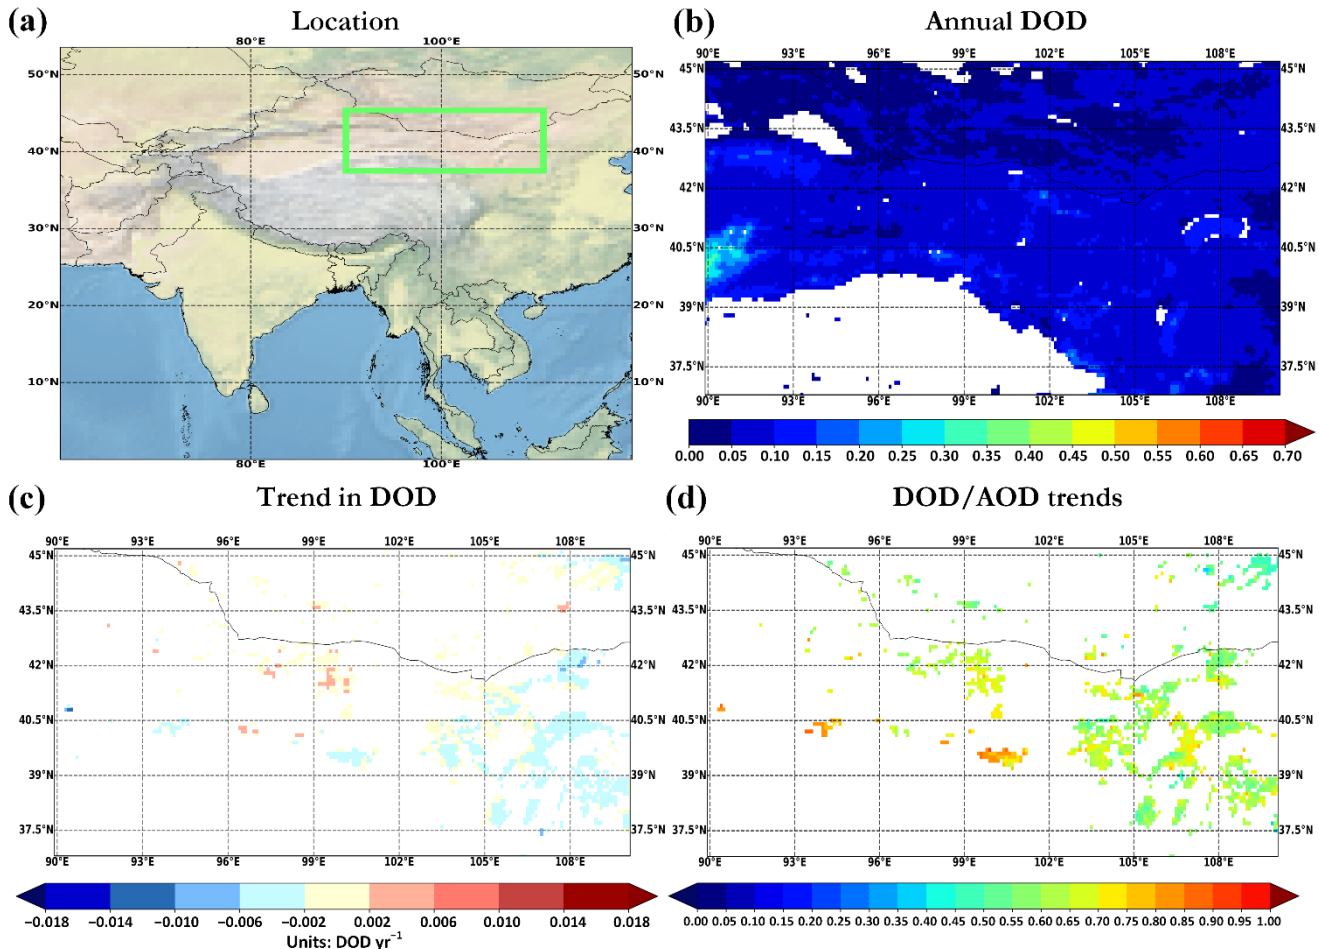

Figure 18: Same as Fig. 10, but for the Gobi Desert.

An et al. (2018) conducted a comprehensive analysis to investigate the potential factors driving the reduction of sand and dust storms, taking place mainly in springtime, in East Asia between 2006 and 2017. In the aforementioned study, across GOB, the mean surface dust concentration was declined by $-31.71 \mu\text{g m}^{-3} \text{yr}^{-1}$ (-12.24%). These declining trends are regulated by changes in the surface conditions (e.g. vegetation coverage) which are strongly linked to precipitation, soil moisture, ambient temperature and human activities. The increasing trends in vegetation coverage are observed using the Normalized Difference Vegetation Index (NDVI) (0.0006yr^{-1}) from MODIS and are linked with the ascending tendencies of the precipitation ($0.002 \text{mm day}^{-1} \text{yr}^{-1}$) and volumetric soil moisture at 0-0.1 m depth (0.316yr^{-1}). All these factors converge towards the reduction of emitted amounts of dust aerosols. Over East Asia, the frequency and intensity of dust outbreaks have been decreased during

680 the springtime (An et al., 2018). Dust particles are primarily uplifted into the surrounding air across this region due to massive
681 winds accompanied by cold air from northern latitudes. The decreasing frequency and intensity of dust outbreaks can be
682 explained by the declining tendencies of the north wind components, documented during 2007–2016. The latter is associated
683 with the decline of 1) Polar Vortex intensity, 2) north-to-south mean surface level pressure gradient and 3) meridional wind
684 component magnitude.

685 **4 Summary and conclusions**

686 Airborne dust affects the global and regional climate via the induced perturbation of the solar and terrestrial radiation
687 fields. Therefore, the investigation of DOD temporal variations is crucial to assess its climatic role as well as the multifarious
688 impacts within the Earth-Atmosphere system and humans' health. The present study deals with the investigation of the annual
689 and seasonal trends of AOD and DOD, both at global and regional scales over the period 2003–2017, relying on the MIDAS
690 fine resolution dataset. Taking advantage of the MIDAS strong capabilities, the DOD trends have been analyzed: (i) by
691 considering different aggregation approaches (i.e. arithmetic and geometric means), (ii) at fine and coarse spatial resolutions,
692 (iii) applying and not applying temporal filters (iv) at annual, seasonal and sub-period time scales (i.e. sliding window) and (v)
693 their contribution to the corresponding tendencies of the total aerosol optical depth. Based on this holistic approach, it is
694 provided a complete overview about the temporal variability of dust loads addressing jointly all the factors determining the
695 sign, the magnitude and the statistical significance of the calculated trends.

696 The validity of the MIDAS DOD trends has been investigated with respect to AERONET cAOD data. This analysis
697 encompassed that MIDAS tendencies are capable to follow those of AERONET either for increasing (at 26 out of 30 stations,
698 86.7%) or decreasing (at 7 out of 11 stations, 63.6%) trends. Point-to-point investigation of the DOD-cAOD trends highlighted
699 the accurate, in terms of magnitude and statistical significance, MIDAS DOD trends either across “dusty” sites or downwind
700 areas.

701 The sensitivity analysis between coarse and fine spatial resolution revealed that the magnitude of AOD and DOD trends
702 are lower for the coarse spatial resolution data. On a regional basis, the calculated AOD/DOD trends revealed a very good
703 agreement in terms of trend magnitude for both spatial scales. In general, coarse resolution data provide better spatial coverage,
704 however, detailed information, in spatial terms, is when fine resolution data are utilized. In addition, the sensitivity analysis
705 on the different aggregation approaches revealed that the arithmetic-based trends are larger than those of the geometric-based
706 ones (from 52.87 to 91.77%) all over the globe. The only exception was found only for AOD at coarse spatial resolution.
707 Lastly, the sensitivity analysis on the temporal filtering in trend calculations indicated new regions (e.g. across oceanic
708 territories) with unphysical unfiltered AOD trends. In addition, unfiltered trends led to poorer performance of MIDAS DOD
709 trends against AERONET retrievals.

710 Based on our analysis, increasing DOD trends are obtained across the Central Sahara and the Arabian Peninsula whereas
711 opposite tendencies are recorded over the Eastern and Western Sahara, the Thar and Gobi Deserts, in the Bodélé Depression

and in southern Mediterranean. On the seasonal basis, the maximum positive DOD trends are displayed in the Central Sahara and Middle East area during summertime. During spring, the strongest reductions of the dust burden have been revealed at the Bodélé Depression whereas reverse tendencies have been recorded in the Western and Eastern Sahara and in the Thar and Taklamakan Deserts during summer. Similarly, the most negative trends were observed at spring over the Gobi Desert. Positive trends across the area extending from North Atlantic Ocean to the eastern Caribbean Sea are observed in spring.

At global scale and separately over continents and oceans, negligible and non-significant DOD trends are found. A similar analysis for 9 specific regions of the planet has been performed revealing evident trends which are not however all of them statistically significant. More specifically, strong DOD trends were documented in Central (0.0021 yr^{-1}) and East (-0.0018 yr^{-1}) Sahara, Bodélé Depression (-0.0055 yr^{-1}), Mediterranean (-0.0011 yr^{-1}) and Thar Desert (-0.0053 yr^{-1}). In contrast, non-significant regional DOD trends were depicted in the Arabian Peninsula and the Gobi Desert. At a regional scale, the calculated trends vary in terms of sign, magnitude and statistical significance, depending on the sub-period, thus indicating a strong interannual variation of dust aerosols' load within the period 2003–2017. In the majority of the regions of interest, including also downwind areas, the variations of the total aerosol load are driven by those of mineral particles.

The obtained findings from the current study highlight the applicability of the MIDAS dataset for detecting dust temporal across various spatial scales. The high spatiotemporal resolution of MIDAS provides the opportunity to complement and further expand the existing knowledge on this critical aspect, yet not well covered in the field of dust research. Likewise, by comparing AOD and DOD tendencies, it is feasible the assessment of mineral particles' role on the variations of the total aerosol load. Our results could be incorporated in chemical models, either for assessing the various impacts of dust and non-dust particles or for evaluating trends based on numerical simulations, and to further improve their calibration and forecast performance. Moreover, the obtained findings here can be used for the interpretation of the trends of the radiation fluxes at the surface and at the top of the atmosphere obtained by observations or atmospheric-aerosol models (Chaibou et al., 2020). The recently published Sixth Assessment Report (AR6) of the Intergovernmental Panel on Climate Change (IPCC) states that the increase of the global dust load causes a reduction of the effective radiative forcing (ERF) by -0.25 Wm^{-2} (Andrews et al., 2017; Forster et al., 2021). Therefore, fluctuations of the dust atmospheric load provide a valuable information in order to understand the associated impacts on past, current and future climate. Finally, the current study focused mainly on the description of dust optical depth trends providing also a preliminary interpretation of the obtained findings. Nevertheless, an in-depth analysis (a follow up study) is ongoing by investigating the role of critical meteorological variables (e.g. wind) as well as of other determinant geophysical factors (e.g. soil moisture, vegetation, land coverage) on the configuration of DOD trends.

750 European Research Council (grant no. 725698; D-TECT). Stelios Kazadzis acknowledges the International Network to
751 Encourage the Use of Monitoring and Forecasting Dust Products (inDust) COST Action CA16202. We gratefully acknowledge
752 the data provided by AERONET network and we wish to express our appreciation to the operators of stations for their efforts
753 on running the instruments.

754 **Author contribution**

755 SAL was responsible for the whole analysis and the preparation of the initial manuscript with support from VS. AG processed
756 the MIDAS dataset and had an advisory role in the relevant parts of the study. AK and SK conceptualized the main objective
757 of the manuscript and supervised the progress. VA provided feedback on the scientific discussions. All authors contributed to
758 the revision and the final editing of the initial manuscript.

759 **Competing interests**

760 The authors declare that they have no competing interests.
