

**Figure S1:** Total aerosol mass concentration during the AQABA campaign, as measured by an Optical Particle Counter in the  $PM_{10}$  size range. The contribution of coarse mode aerosol was estimated in form of the  $(PM_{10}-PM_1)/PM_{10}$  ratio. Highest  $PM_{10}$  concentrations were on both legs observed in the transitional area between Red Sea and Arabian Sea, where coarse mode aerosol contributed ca. > 90 % to the total aerosol mass concentration.

**Figure S2:** NO<sub>x</sub>, NO<sub>y</sub> and NO<sub>z</sub> measured by TD-CRDS (5 minute averages). Periods during which the measurement was contaminated by the ship's stack are highlighted in grey. The first leg ended on the 31 July, the 2<sup>nd</sup> leg started on 3 August 2017 after anchorage in Kuwait. The two lowest panels indicate prevailing temperature, relative humidity, wind direction and wind speed.

5 **Figure S3:**  $\text{NO}_x$  (a) and  $\text{NO}_z$  (b) mixing ratios during the first leg of AQABA. The data points are 30 min averages, periods contaminated with ship stack contamination (e.g. most of the Arabian Sea) have been removed. HYSPLIT back trajectories (48 hours) are indicated with grey lines in (a). Elevated  $\text{NO}_z$  mixing ratios above 2.5 ppbv were encountered in the Arabian Gulf.

**Figure S4:** Comparison between measured OH concentrations and the interpolated trace based on  $J_{\text{O1D}}$  (see Sect. 3.1.3) in (a)

5 the Mediterranean Sea, (b) the Red Sea, and (c) the Arabian Gulf.

**Figure S5:** Time series of  $\text{NO}_x$  and  $\text{SO}_2$  in (a) the Mediterranean Sea, (b) the Red Sea, and (c) the Arabian Gulf.
