30 **Abstract**

31 Nitryl chloride (ClNO<sub>2</sub>), an important precursor of Cl atoms, significantly affects atmospheric  
32 oxidation capacity and O<sub>3</sub> formation. However, sources of ClNO<sub>2</sub> in inland China have not been  
33 fully elucidated. In this work, laboratory experiments were conducted to investigate heterogeneous  
34 reactions of N<sub>2</sub>O<sub>5</sub> with eight saline mineral dust samples collected from different regions in China,  
35 and substantial formation of ClNO<sub>2</sub> was observed **in these reactions**. ClNO<sub>2</sub> yields,  $\varphi(\text{ClNO}_2)$ ,  
36 showed large variations (ranging from <0.05 to ~0.77) for different saline mineral dust samples,  
37 depending on mass fractions of particulate chloride. In addition,  $\varphi(\text{ClNO}_2)$  could increase, decrease  
38 or show insignificant change for different saline mineral dust samples **when relative humidity (RH)**  
39 increased from 18% to 75%. We further found that current parameterizations significantly  
40 overestimated  $\varphi(\text{ClNO}_2)$  for heterogeneous uptake of N<sub>2</sub>O<sub>5</sub> onto saline mineral dust. In addition,  
41 assuming a uniform  $\varphi(\text{ClNO}_2)$  value of 0.10 for N<sub>2</sub>O<sub>5</sub> uptake onto mineral dust, we used a 3-D  
42 chemical transport model to assess the impact of this reaction on tropospheric ClNO<sub>2</sub> in China,  
43 and found that weekly mean nighttime maximum ClNO<sub>2</sub> mixing ratios could **have been** increased  
44 by up to 85 pptv during a severe dust event in May 2017. Overall, our work showed that  
45 heterogeneous reaction of N<sub>2</sub>O<sub>5</sub> with saline mineral dust could be an important source of  
46 tropospheric ClNO<sub>2</sub> in inland China.

47

## 48 **1 Introduction**

49 The formation of O<sub>3</sub> and secondary aerosols, two major air pollutants, is closely related to  
50 atmospheric oxidation processes (Lu et al., 2019). Primary pollutants emitted by natural and  
51 anthropogenic sources are oxidized by various oxidants to produce O<sub>3</sub> and secondary aerosols,  
52 affecting air quality and climate. Major tropospheric oxidants include OH radicals, NO<sub>3</sub> radicals  
53 and O<sub>3</sub>, and in the last two decades Cl atoms have been proposed as an important oxidant (Saiz-  
54 Lopez and von Glasow, 2012; Simpson et al., 2015; Wang et al., 2019). Rate constants for reactions  
55 of certain volatile organic compounds (VOCs) with Cl atoms can be a few orders of magnitude  
56 larger than those reacting with OH radicals (Atkinson and Arey, 2003; Atkinson et al., 2006);  
57 therefore, despite its lower concentrations in the troposphere, Cl can contribute significantly to  
58 atmospheric oxidation capacity in some regions (Saiz-Lopez and von Glasow, 2012; Simpson et  
59 al., 2015; Wang et al., 2019). For example, a modeling study (Sarwar et al., 2014) suggested that  
60 including Cl chemistry in the model could enhance oxidative degradation of VOCs by >20% in  
61 some locations.

62 One major source of tropospheric Cl atoms is daytime photolysis of ClNO<sub>2</sub> (Thornton et al.,  
63 2010; Simpson et al., 2015), which is formed in heterogeneous reaction of N<sub>2</sub>O<sub>5</sub> with chlorine-  
64 containing particles (R1) at nighttime (Osthoff et al., 2008; Thornton et al., 2010):

66 The uptake coefficient,  $\gamma(\text{N}_2\text{O}_5)$ , and the ClNO<sub>2</sub> yield,  $\varphi(\text{ClNO}_2)$ , both depend on relative humidity  
67 (RH), aerosol composition and mixing state, and etc. (Bertram and Thornton, 2009; Ryder et al.,  
68 2014; Mitroo et al., 2019; McNamara et al., 2020; Yu et al., 2020). Cl atoms produced by ClNO<sub>2</sub>  
69 photolysis can effectively enhance atmospheric oxidation (Le Breton et al., 2018; Wang et al.,  
70 2019) and thus increase concentrations of O<sub>3</sub> and OH radicals during the day (Simon et al., 2009;

71 Riedel et al., 2014; Sarwar et al., 2014; Tham et al., 2016; Wang et al., 2016). In addition, ClNO<sub>2</sub>  
72 is an important temporary reservoir of NO<sub>x</sub> at night and releases NO<sub>2</sub> during the daytime via  
73 photolysis, thereby further affecting daytime photochemistry.

74 Sea spray aerosol is the most important source of particulate chloride (Cl<sup>-</sup>), and ClNO<sub>2</sub> is  
75 expected to be abundant at marine and coastal regions impacted by anthropogenic emissions. High  
76 levels of ClNO<sub>2</sub> have been observed at various marine and coastal regions over the globe (Simon  
77 et al., 2009; Riedel et al., 2012; Tham et al., 2014; Young et al., 2014; Wang et al., 2016; Osthoff  
78 et al., 2018; Wang et al., 2020a; Yu et al., 2020). In addition, many studies (Thornton et al., 2010;  
79 Mielke et al., 2011; Phillips et al., 2012; Riedel et al., 2013; Bannan et al., 2015; Faxon et al., 2015;  
80 Wang et al., 2017b; Wang et al., 2017c; Tham et al., 2018; Wang et al., 2018) have also reported  
81 significant amounts of ClNO<sub>2</sub> at various continental sites with limited marine influence. For  
82 example, ClNO<sub>2</sub> concentrations reached 4 ppbv in the summer of North China Plain (Tham et al.,  
83 2016). These observations imply the importance of other sources for aerosol chloride, such as coal  
84 combustion (Eger et al., 2019), biomass burning (Ahern et al., 2017), waste incineration (Bannan  
85 et al., 2019), and snow-melting agent application (Mielke et al., 2016; McNamara et al., 2020).

86 In addition to insoluble minerals (e.g., quartz, feldspar, clay and carbonate), mineral dust  
87 aerosols emitted from saline topsoil in arid and semi-arid regions may contain significant amounts  
88 of soluble materials such as chloride and sulfate (Gillette et al., 1992; Abuduwailli et al., 2008;  
89 Zhang et al., 2009; Wang et al., 2012; Jordan et al., 2015; Frie et al., 2017; Gaston et al., 2017;  
90 Tang et al., 2019; Gaston, 2020). As elemental and mineralogical compositions are different for  
91 conventional and saline mineral dust, they would differ significantly in physicochemical properties  
92 and impacts on atmospheric chemistry and climate. For example, hygroscopicity and cloud  
93 condensation nuclei (CCN) activities of saline mineral dust can be much higher than conventional

94 mineral dust (Pratt et al., 2010; Gaston et al., 2017; Tang et al., 2019; Zhang et al., 2020). Recent  
95 laboratory studies (Mitroo et al., 2019; Royer et al., 2021) found that heterogeneous reactions of  
96  $\text{N}_2\text{O}_5$  with saline mineral dust originating from western and southwestern USA can be very  
97 effective and produce significant amounts of  $\text{ClNO}_2$ . Large variations in  $\gamma(\text{N}_2\text{O}_5)$  and  $\phi(\text{ClNO}_2)$   
98 were reported (Mitroo et al., 2019; Royer et al., 2021), depending on RH as well as chemical and  
99 mineralogical contents of saline mineral dust samples.

100 A very recent study (Wu et al., 2020) showed that  $\text{N}_2\text{O}_5$  uptake onto saline mineral dust  
101 contributed significantly to particulate nitrate formation during a dust storm event in Shanghai,  
102 China. One may further expect that it may have a profound effect on  $\text{ClNO}_2$ , especially considering  
103 that vast areas in China are heavily affected by both mineral dust and  $\text{NO}_x$ . Nevertheless,  
104 heterogeneous formation of  $\text{ClNO}_2$  from  $\text{N}_2\text{O}_5$  uptake onto saline mineral dust in other regions  
105 rather than USA has not been explored. In order to provide key parameters required to assess the  
106 potential of saline mineral dust as a  $\text{ClNO}_2$  source in China, we conducted a series of laboratory  
107 experiments to investigate  $\text{ClNO}_2$  formation in heterogeneous reaction of  $\text{N}_2\text{O}_5$  with several saline  
108 mineral dust samples collected from different regions in China. In addition to difference in source  
109 regions, saline mineral dust samples examined in our work have substantial variations in  
110 composition and mineralogy, enabling us to examine the effects of particle composition and water  
111 content on  $\text{ClNO}_2$  production. In order to better understand variations of  $\text{ClNO}_2$  yields with RH  
112 and samples, we experimentally measured mass hygroscopic growth factors of the eight samples  
113 examined, while previous studies (Mitroo et al., 2019; Royer et al., 2021) used the thermodynamic  
114 model ISORROPIA-II (Fountoukis and Nenes, 2007) to predict particulate water contents. Based  
115 on our laboratory results, we further use a 3-D chemical transport model (GEOS-Chem) to assess

116 the impacts of ClNO<sub>2</sub> produced from N<sub>2</sub>O<sub>5</sub> uptake onto mineral dust on ClNO<sub>2</sub> and O<sub>3</sub> in China  
117 during a major dust event which occurred in May 2017.

## 118 **2 Methodology**

### 119 **2.1 Characterization of saline mineral dust samples**

120 Eight saline mineral dust samples, originating from five different provinces in northern China  
121 (including Ningxia, Xinjiang, Shandong, Inner Mongolia and Shaanxi), were examined in this  
122 work, and full information of these samples can be found elsewhere (Tang et al., 2019). Table 1  
123 summarizes key information of these samples. According to their chloride contents, the eight  
124 samples were classified into three categories, including two high chloride samples (H1 and H2),  
125 four medium chloride samples (M1, M2, M3 and M4) and two low chloride samples (L1 and L2).

126 Our previous work (Tang et al., 2019; Zhang et al., 2020) measured mass hygroscopic growth  
127 factors of the eight samples at 0-90% RH with a RH resolution of 10%, using a vapor sorption  
128 analyzer (Gu et al., 2017). As the highest RH at which heterogeneous reaction of N<sub>2</sub>O<sub>5</sub> with saline  
129 mineral dust was conducted in our work was ~75%, we further measured mass growth factors of  
130 the eight samples at (75±2)% RH, and the results are also included in Table 1.

131  
132 **Table 1.** Overview of mass fractions of major soluble ions and mass ratios of particulate water at  
133 (75±2)% RH to dry particles for the eight saline mineral dust samples examined in this work. Mass  
134 fractions of major soluble ions were reported previously (Tang et al., 2019), and particulate water  
135 contents at (75±2)% RH were measured by the present work.

 137 work (Tang et al., 2019).

## 138 2.2 Experimental apparatus

139 Figure 1 shows the experimental apparatus used to study heterogeneous interactions of N<sub>2</sub>O<sub>5</sub>  
 140 with saline mineral dust. It mainly consists of three parts: 1) N<sub>2</sub>O<sub>5</sub> generation, 2) gas-particle  
 141 interaction, and 3) detection of N<sub>2</sub>O<sub>5</sub> and ClNO<sub>2</sub>.

142  
 143 **Figure 1.** Schematic diagram of the experimental apparatus.

### 144 2.2.1 N<sub>2</sub>O<sub>5</sub> generation

145 In our work, N<sub>2</sub>O<sub>5</sub> was generated via oxidation of NO<sub>2</sub> by O<sub>3</sub>. As shown in Figure 1, a  
 146 synthetic air flow (30 mL/min) was passed over a Hg lamp to produce O<sub>3</sub> via O<sub>2</sub> photolysis at  
 147 184.95 nm. The photolysis module was stabilized at 35±0.2 °C using a Peltier cooler controlled by  
 148 a Proportion Integration Differentiation (PID) algorithm, in order to give stable O<sub>3</sub> output. The

149 O<sub>3</sub>/air flow was then mixed with a NO<sub>2</sub> flow (80 mL/min, 10 ppmv in synthetic air) in a  
150 temperature-stabilized PFA reactor with a residence time of ~70 s to produce N<sub>2</sub>O<sub>5</sub>. After exiting  
151 the PFA reactor, the flow (110 mL/min) was then diluted with a humidified nitrogen flow (2500  
152 mL/min), and RH of the humidified nitrogen flow was monitored using a hygrometer. The final  
153 flow had a total flow rate of 2610 mL/min.

### 154 **2.2.2 Heterogeneous interactions**

155 As shown in Figure 1, the mixed flow (2610 mL/min) could be directed through a blank PTFE  
156 membrane filter (47 mm, Whatman, USA) housed in a PFA filter holder, and in this case initial  
157 N<sub>2</sub>O<sub>5</sub> and ClNO<sub>2</sub> concentrations were measured; in our experiments, initial N<sub>2</sub>O<sub>5</sub> concentrations  
158 were in the range of 0.4-1.0 ppbv. Alternatively, the flow could also be passed through a PTFE  
159 filter loaded with saline mineral dust, and thus N<sub>2</sub>O<sub>5</sub> and ClNO<sub>2</sub> concentrations after heterogeneous  
160 reaction with saline mineral dust loaded on the filter were measured. During our experiments, the  
161 flow could be switched back to pass through the blank filter in order to check whether the initial  
162 N<sub>2</sub>O<sub>5</sub> and ClNO<sub>2</sub> concentrations were stable.

163 Saline mineral dust particles were loaded onto PTFE filters using the method described in our  
164 previous study (Li et al., 2020; Jia et al., 2021). In brief, 10 mL particle/ethanol mixture was  
165 transferred onto a PTFE filter, and after ethanol was evaporated a relatively uniform particle film,  
166 as revealed by visual inspection, was formed on the filter. PTFE filters were weighted before and  
167 after being loaded with particles, in order to determine the mass of particles loaded onto these  
168 filters. In our work, the mass of particles on filters were in range of 0.6-7.3 mg.

### 169 **2.2.3 Detection of N<sub>2</sub>O<sub>5</sub> and ClNO<sub>2</sub>**

170 After exiting one of the two filters, a flow of 2200 mL/min was sampled into a time-of-flight  
171 chemical ionization mass spectrometry (TOF-CIMS) to measure N<sub>2</sub>O<sub>5</sub> and ClNO<sub>2</sub> concentrations,

172 and the remaining flow (~400 mL/min) went into the exhaust. The CIMS instrument has been  
173 detailed previously (Kercher et al., 2009; Wang et al., 2016). In brief, N<sub>2</sub>O<sub>5</sub> and ClNO<sub>2</sub> were  
174 detected as I(N<sub>2</sub>O<sub>5</sub>)<sup>-</sup> and I(ClNO<sub>2</sub>)<sup>-</sup> clusters at 235 and 208 m/z (R2a, R2b) using I<sup>-</sup> as the reagent  
175 ion, and a soft X-ray device (Hamamatsu, Soft X-Ray 120°) was employed to generate I<sup>-</sup> from  
176 CH<sub>3</sub>I/N<sub>2</sub>. CIMS was calibrated before and after our experiments which lasted for ~1 month, and  
177 further details on calibration can be found in the Appendix. The detection limits were 2 pptv for  
178 N<sub>2</sub>O<sub>5</sub> and 3 pptv for ClNO<sub>2</sub>, calculated as four times of standard deviations (4 σ) when measuring  
179 blank samples with 1 min average, and the accuracy was estimated to be ~25%.

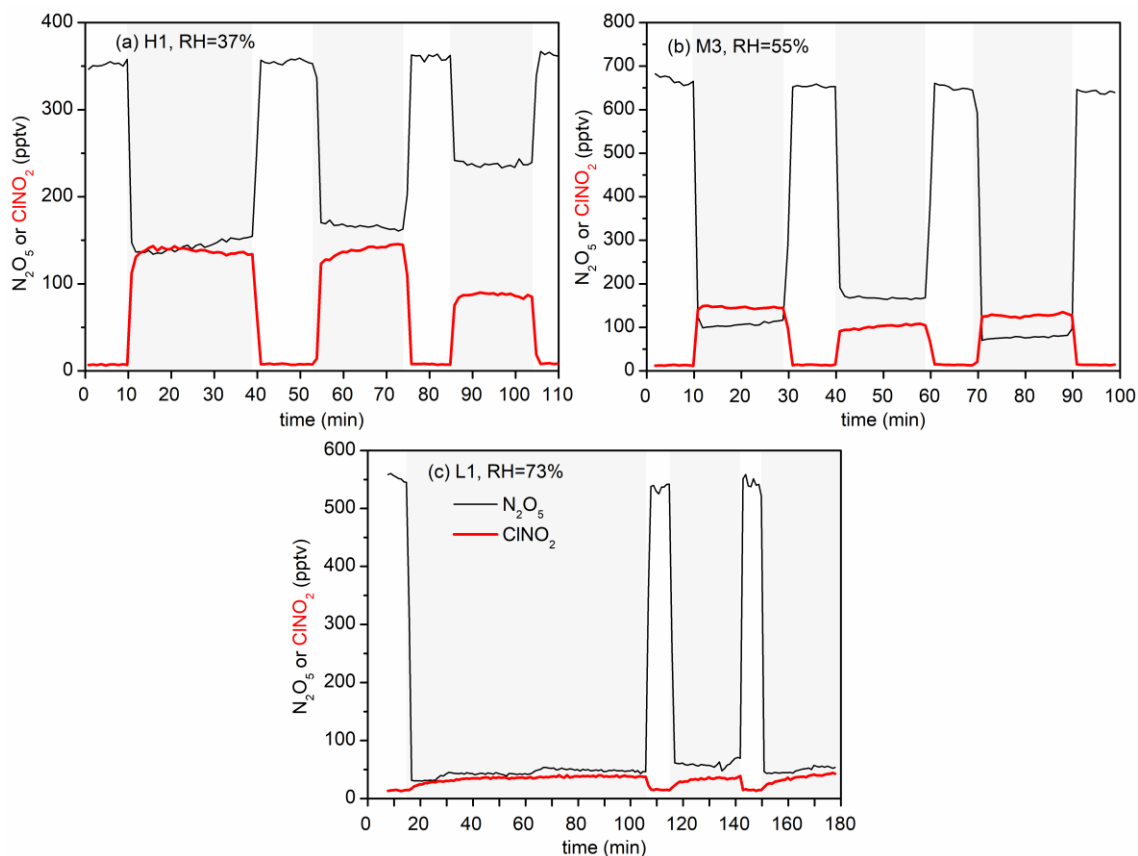

### 182 **2.3 Model description**

183 We use GEOS-Chem (version 12.9.3) to quantify the effects of ClNO<sub>2</sub> formation due to  
184 heterogeneous reaction of N<sub>2</sub>O<sub>5</sub> with saline dust in China. The model, which includes a detailed  
185 representation of coupled ozone-NO<sub>x</sub>-VOCs-aerosol-halogen chemistry (Wang et al., 2021), is  
186 driven by MERRA2 (the Modern-Era Retrospective Analysis for Research and Applications,  
187 Version 2) assimilated meteorological fields from the NASA Global Modeling and Assimilation  
188 Office (GMAO) with native horizontal resolution of 0.25°×0.3125° and 72 vertical levels from the  
189 surface to the mesosphere. Our simulation was conducted over East Asia (60°-150°E, 10°S-55°N)  
190 at the native resolution with dynamical boundary conditions from a 4°×5° global simulation.  
191 Anthropogenic emissions in China are based on the Multiresolution Emission Inventory for China  
192 (MEIC) (Zheng et al., 2018) and an inventory of HCl and fine particulate Cl<sup>-</sup> in China (Fu et al.,  
193 2018). Natural dust emissions are calculated based on Ridley et al. Ridley et al. (2013). A more  
194 detailed description of the model and emissions can be found elsewhere (Wang et al., 2020b).

195 For  $\text{N}_2\text{O}_5$  uptake onto aqueous aerosols, the parameterization in our previous study (Wang et  
196 al., 2020b) for  $\gamma(\text{N}_2\text{O}_5)$  and  $\varphi(\text{ClNO}_2)$ , which are based on a detail evaluation of different model  
197 parameterizations by previous work (McDuffie et al., 2018a; McDuffie et al., 2018b), is used in  
198 this study, and more details can be found in the supplement. For  $\text{N}_2\text{O}_5$  uptake on dust aerosol,  
199  $\gamma(\text{N}_2\text{O}_5)$  is always assumed to be 0.02, as recommended previously (Crowley et al., 2010; Tang et  
200 al., 2017), and  $\varphi(\text{ClNO}_2)$  is assumed to be 0 in the standard case, i.e., no  $\text{ClNO}_2$  is produced in  
201 heterogeneous reaction of  $\text{N}_2\text{O}_5$  with mineral dust.

### 202 **3 Results and discussion**

203 Figure 2a shows changes in  $\text{N}_2\text{O}_5$  and  $\text{ClNO}_2$  concentrations during an experiment in which  
204 heterogeneous reaction of  $\text{N}_2\text{O}_5$  with sample H1 at 37% RH was studied. As shown in Figure 2a,  
205 when the mixed flow was passed through the blank filter (0-10 min),  $\text{N}_2\text{O}_5$  concentrations were  
206 measured to be  $\sim 350$  pptv and  $\text{ClNO}_2$  was below the detection limit. The mixed flow was then  
207 passed through the particle-loaded filter at  $\sim 10$  min in order to initiate heterogeneous reaction of  
208  $\text{N}_2\text{O}_5$  with sample H1, and significant decrease in  $\text{N}_2\text{O}_5$  concentrations (from  $\sim 350$  to  $\sim 150$  pptv)  
209 and increase in  $\text{ClNO}_2$  concentrations (from almost 0 to  $\sim 150$  pptv) were observed, suggesting that  
210 heterogeneous interaction with sample H1 substantially consumed  $\text{N}_2\text{O}_5$  and generated  $\text{ClNO}_2$ . In  
211 order to check if initial  $\text{N}_2\text{O}_5$  and  $\text{ClNO}_2$  concentrations were stable, during our experiments the  
212 mixed flow was switched back to pass through the blank filter from time to time (e.g., at around  
213 40, 75 and 105 min for the experiment displayed in Figure 2a). Indeed, initial  $\text{N}_2\text{O}_5$  and  $\text{ClNO}_2$   
214 concentrations were constant in our experiments, with another two examples shown in Figures 2b  
215 and 2c.

216  
 217 **Figure 2.** Time series for measured  $N_2O_5$  and  $ClNO_2$  concentrations after the mixed flow was  
 218 passed through the blank filter or the particle-loaded filter: a) H1, 37% RH; b) M3, 55% RH; c)  
 219 L1, 73% RH. Periods in which the mixed flow was passed through the particle-loaded filter was  
 220 shadowed with gray.

221  
 222 Figures 2b and 2c show time series of measured  $N_2O_5$  and  $ClNO_2$  concentrations in another  
 223 two experiments, suggesting that heterogeneous reaction with sample M3 and L1 also led to  
 224 substantial removal of  $N_2O_5$ . However, much less  $ClNO_2$  was produced for sample M3 and L1,  
 225 when compared to sample H1 (Figure 2a). The decrease in  $N_2O_5$  concentrations,  $\Delta[N_2O_5]$ , and the  
 226 increase in  $ClNO_2$  concentrations,  $\Delta[ClNO_2]$ , can be used to calculate  $ClNO_2$  yields,  $\phi(ClNO_2)$ ,  
 227 according to Eq. (1).

228 
$$\varphi(\text{ClNO}_2) = \frac{\Delta[\text{ClNO}_2]}{\Delta[\text{N}_2\text{O}_5]} \quad (1)$$

229 In this work we measured  $\varphi(\text{ClNO}_2)$  for heterogeneous reaction of  $\text{N}_2\text{O}_5$  with eight different  
 230 saline mineral dust samples at four RH, and each experiment was repeated at least three times. It  
 231 should be mentioned that during each experiment the measured  $\varphi(\text{ClNO}_2)$  did not vary  
 232 significantly with time, and therefore an average value of  $\varphi(\text{ClNO}_2)$  was reported for each  
 233 experiment. Table 2 summarizes measured  $\varphi(\text{ClNO}_2)$  for the eight samples at different RH, and  
 234 the results are further discussed in the following sections.

235

236 **Table 2.** Measured  $\text{ClNO}_2$  yields for heterogeneous uptake of  $\text{N}_2\text{O}_5$  onto saline mineral dust  
 237 samples at different RH. All the errors given in this work are standard deviations. The uncertainty  
 238 of RH was  $\pm 2\%$ .

sample	18% RH	36% RH	56% RH	75% RH
H1	0.402±0.138	0.663±0.039	0.774±0.028	0.697±0.311

### 240 3.1 $\text{ClNO}_2$ production yields

241 Figure 3 shows  $\text{ClNO}_2$  yields as a function of RH for the two samples with high chloride  
 242 content (H1 and H2), and  $\varphi(\text{ClNO}_2)$  were found to be quite high for the two samples. To be more  
 243 specific, the mass fraction of chloride was 0.3870 for sample H1, and  $\varphi(\text{ClNO}_2)$  were found to  
 244 increase from 0.402±0.138 at 18% RH to 0.774±0.028 at 56% RH, and then slightly decreased to

245  $0.697 \pm 0.311$  when RH was further increased to 75%. For sample H2, the mass fraction of chloride  
 246 (0.2145) was lower than sample H1, and  $\varphi(\text{ClNO}_2)$  showed a small decrease (or remained  
 247 relatively constant) when RH was increased from 18% to 56%, ranging from  $0.474 \pm 0.026$  to  
 248  $0.560 \pm 0.046$ ; further increase in RH to 75% resulted in small decrease in  $\varphi(\text{ClNO}_2)$  to  $0.378 \pm 0.069$ .

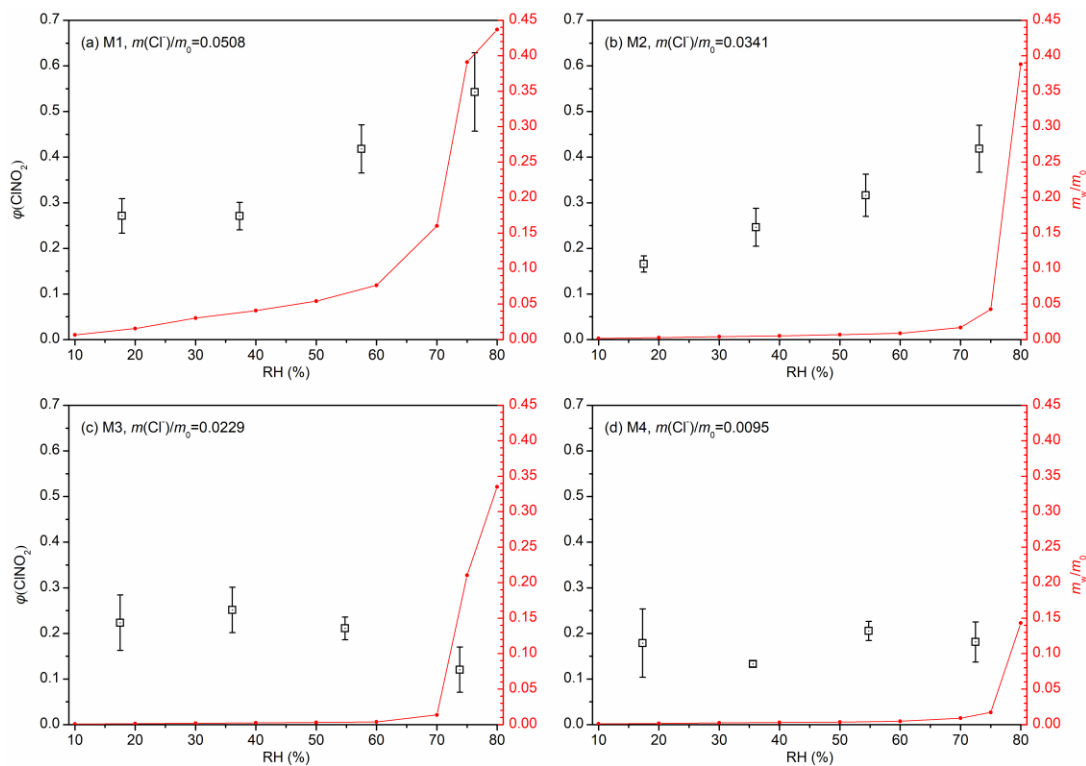

249  
 250 **Figure 3.** Measured  $\text{ClNO}_2$  yields (black symbol) and  $m_w/m_0$  (red line) as a function of RH for (a)  
 251 H1 and (b) H2. The error bar represents standard deviation, and  $m_w/m_0$  represents normalized mass  
 252 of particulate water (normalized to the mass of dry particles), which was measured as the relative  
 253 increase in particle mass at a given RH compared to <1% RH.

254  
 255  $\text{ClNO}_2$  yields are shown in Figure 4 as a function of RH for the two low chloride samples (L1  
 256 and L2), and their mass fractions of chloride were <0.01. As shown in Figure 4,  $\varphi(\text{ClNO}_2)$  were  
 257 found to be always <0.05 for the two samples, suggesting that heterogeneous production of  $\text{ClNO}_2$   
 258 was very limited, despite substantial removal of  $\text{N}_2\text{O}_5$  due to heterogeneous reaction (with an  
 259 example shown in Figure 2c). The low  $\varphi(\text{ClNO}_2)$  values for sample L1 and L2 could be attributed  
 260 to their low chloride contents. In addition,  $\varphi(\text{ClNO}_2)$  appeared to increase with RH for L1 and L2;  
 261 however, since the uncertainties associated with  $\varphi(\text{ClNO}_2)$  were rather large for these two samples,  
 262 the dependence of  $\varphi(\text{ClNO}_2)$  on RH should be treated in caution.

263  
 264 **Figure 4.** Measured  $\text{ClNO}_2$  yields (black symbol) and  $m_w/m_0$  (red line) as a function of RH for (a)  
 265 L1 and (b) L2. The error bar represents standard deviation, and  $m_w/m_0$  represents normalized mass  
 266 of particulate water (normalized to the mass of dry particles), which was measured as the relative  
 267 increase in particle mass at a given RH compared to <1% RH.

268  
 269 We also investigated  $\text{ClNO}_2$  production from heterogeneous reaction of  $\text{N}_2\text{O}_5$  with four  
 270 samples with medium chloride contents (M1, M2, M3 and M4), and the results are displayed in  
 271 Figure 5. Mass fractions of chloride were determined to be 0.0508 for M1, 0.034 for M2, 0.0229  
 272 for M3 and 0.0095 for M4, respectively.  $\text{ClNO}_2$  yields were found to increase significantly with  
 273 RH for M1 and M2; more specifically,  $\varphi(\text{ClNO}_2)$  increased from  $0.271 \pm 0.038$  at 18% RH to  
 274  $0.543 \pm 0.086$  at 75% RH for sample M1, and increased from  $0.166 \pm 0.018$  at 18% RH to  
 275  $0.418 \pm 0.0052$  at 75% RH for sample M2. As shown in Figure 5, the dependence of  $\varphi(\text{ClNO}_2)$  on  
 276 RH for the other two medium chloride samples (M3 and M4) were rather different from M1 and  
 277 M2. For sample M3,  $\varphi(\text{ClNO}_2)$  first increased from  $0.223 \pm 0.061$  at 18% RH to  $0.251 \pm 0.050$  at 36%  
 278 RH, and further increase in RH to 75% caused substantial reduction in  $\varphi(\text{ClNO}_2)$ . At last, no  
 279 significant variation of  $\varphi(\text{ClNO}_2)$  with RH (18-75%) was observed for sample M4.

280  
 281 **Figure 5.** Measured  $\text{ClNO}_2$  yields (black symbol) and  $m_w/m_0$  (red line) as a function of RH for (a)  
 282 M1, (b) M2, (c) M3, and (d) M4. The error bar represents standard deviation, and  $m_w/m_0$  represents  
 283 normalized mass of particulate water (normalized to the mass of dry particles), which was  
 284 measured as the relative increase in particle mass at a given RH compared to <1% RH.

285  
 286 **3.2 The effects of RH**

287 The dependence of  $\varphi(\text{ClNO}_2)$  on RH for the eight saline mineral samples we examined, as  
 288 discussed in Section 3.1, exhibited two interesting features. First, when RH was as low as 18%,  
 289 large  $\varphi(\text{ClNO}_2)$  values ( $>0.2$ ) were observed for four samples (H1, H2, M1 and M3). As the  
 290 deliquescence RH of NaCl is  $\sim 75\%$ , one may wonder where aqueous chloride, which is necessary  
 291 for heterogeneous formation of  $\text{ClNO}_2$ , came from at 18% RH. As initially suggested by a previous  
 292 study (Mitroo et al., 2019), the occurrence of aqueous chloride in saline mineral dust particles at  
 293 low RH could be due to the presence of  $\text{CaCl}_2$  and  $\text{MgCl}_2$ , which were amorphous under dry

294 conditions and could take up water at very low RH (Guo et al., 2019). Our previous study (Tang  
295 et al., 2019) measured water soluble ions contained by the eight saline mineral dust samples, and  
296 as shown in Figure S1, the amounts of water soluble  $\text{Ca}^{2+}$  in the four samples (H1, H2, M1 and  
297 M3) with larger  $\varphi(\text{ClNO}_2)$  at 18% RH were significantly larger than those in the other four samples  
298 (M2, M4, L1 and L2). This observation further supported our deduction that the presence of  $\text{CaCl}_2$   
299 enabled efficient formation of  $\text{ClNO}_2$  at low RH.

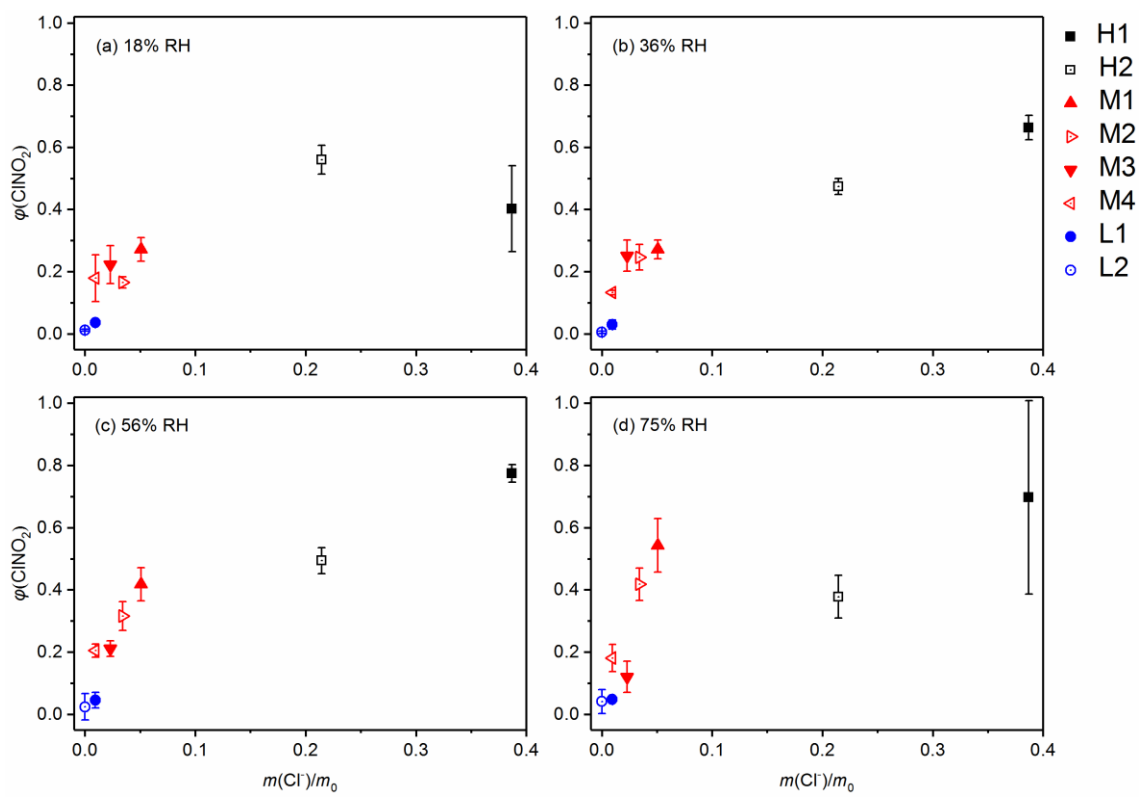

300 The second interesting feature is that as shown in Figures 3-5,  $\varphi(\text{ClNO}_2)$  could increase,  
301 decrease or remain relatively constant with increase in RH from 18% to 75%. This feature can be  
302 understood given the complex mechanisms driving heterogeneous uptake of  $\text{N}_2\text{O}_5$  onto saline  
303 mineral dust (Mitroo et al., 2019; Royer et al., 2021): at a given RH,  $\text{N}_2\text{O}_5$  can react with aqueous  
304 water, aqueous chloride and insoluble minerals, and only its reaction with aqueous chloride would  
305 produce  $\text{ClNO}_2$ . The possible effects of RH on  $\varphi(\text{ClNO}_2)$  are discussed below: 1) as RH increases,  
306 heterogeneous reactivity of  $\text{N}_2\text{O}_5$  towards insoluble minerals can be enhanced, suppressed or  
307 remain largely unchanged (Tang et al., 2012; Tang et al., 2017); 2) increase in RH would lead to  
308 further hygroscopic growth and dilution of aqueous solutions, leading to decrease in  $\varphi(\text{ClNO}_2)$  in  
309 this aspect; 3) the increase in particulate water with RH would cause more chloride to be dissolved  
310 into aqueous solutions, and in this aspect increase in RH would promote  $\text{ClNO}_2$  formation. As a  
311 result, it is not surprised to observe different dependence of  $\varphi(\text{ClNO}_2)$  on RH for different saline  
312 mineral dust samples.

313

### 314 **3.3 Discussion**

315 Figure 6 shows the dependence of  $\varphi(\text{ClNO}_2)$  on mass fractions of chloride for the eight  
316 samples we examined at four different RH. These samples showed significant variation in

317  $\varphi(\text{ClNO}_2)$ , ranging from  $<0.1$  to  $>0.7$ , and  $\varphi(\text{ClNO}_2)$  were largest for the two high chloride samples  
 318 (H1 and H2), followed by median (M1, M2, M3 and M4) and low chloride samples (L1 and L2).  
 319 Overall, a positive dependence of  $\varphi(\text{ClNO}_2)$  on mass fractions of chloride was observed at each  
 320 RH. Figure 6 also reveals that the measured  $\varphi(\text{ClNO}_2)$  were very sensitive to mass fractions of  
 321 chloride when the mass fractions of chloride were below 10%. However, as shown in Figure 6,  
 322 higher chloride contents did not always mean larger  $\varphi(\text{ClNO}_2)$ , and similar observations were also  
 323 reported by previous work (Mitroo et al., 2019; Royer et al., 2021). Furthermore, Figure 6 suggests  
 324 that when mass fractions of chloride was  $<10\%$ , the dependence of  $\varphi(\text{ClNO}_2)$  on Cl contents was  
 325 stronger at higher RH. This is because increase in RH would promote dissolution of chloride to  
 326 aqueous water and thus enhance  $\text{ClNO}_2$  formation.

327  
 328 **Figure 6.** Dependence of  $\text{ClNO}_2$  yields on mass fractions of chloride for the eight saline mineral  
 329 dust samples at a given RH: a) 18% RH; b) 36% RH; c) 56% RH; d) 75% RH.

330

331 Two parameterizations have been widely used to predict the dependence of  $\varphi(\text{ClNO}_2)$  on  
332 chemical compositions and water contents of aqueous aerosol particles (Bertram and Thornton,  
333 2009; Yu et al., 2020). Based on laboratory results, Bertram and Thornton (2009) suggested that  
334  $\text{ClNO}_2$  yields can be calculated using Eq. (2):

$$335 \quad \varphi(\text{ClNO}_2) = \left(1 + \frac{k(\text{H}_2\text{O}) \cdot [\text{H}_2\text{O}_{(\text{aq})}]}{k(\text{Cl}^-) \cdot [\text{Cl}^-]}\right)^{-1} \quad (2)$$

336 where  $[\text{H}_2\text{O}_{(\text{aq})}]/[\text{Cl}^-]$  is the ratio of molar concentration of  $\text{H}_2\text{O}$  to that of  $\text{Cl}^-$  in aqueous particles,  
337 and the value of  $k(\text{H}_2\text{O})/k(\text{Cl}^-)$  was suggested to be  $1/(483 \pm 175)$  (Bertram and Thornton, 2009).  
338 Very recently, Yu et al. (2020) examined uptake coefficients of  $\text{N}_2\text{O}_5$  onto ambient aerosol  
339 particles at four different sites in China, and suggested that using a value of  $1/(105 \pm 37)$  for  
340  $k(\text{H}_2\text{O})/k(\text{Cl}^-)$  would lead to better agreement between measured and predicted uptake coefficients  
341 of  $\text{N}_2\text{O}_5$  (Yu et al., 2020).

342 The two parameterizations were used in our work to calculate  $\varphi(\text{ClNO}_2)$  at 75% RH for the  
343 eight saline mineral dust samples we examined.  $[\text{H}_2\text{O}_{(\text{aq})}]/[\text{Cl}^-]$  was calculated from the measured  
344 mass growth factors at 75% RH and the mass fractions of chloride, assuming that all the chloride  
345 contained by saline mineral dust samples was dissolved into aqueous solutions at 75% RH. The  
346 comparison between measured and calculated  $\varphi(\text{ClNO}_2)$  is displayed in Figure 7, suggesting that  
347 both parameterizations significantly overestimated the measured  $\varphi(\text{ClNO}_2)$  for all the eight saline  
348 mineral dust samples we investigated. A previous study (Mitroo et al., 2019) investigated  $\varphi(\text{ClNO}_2)$   
349 for heterogeneous uptake of  $\text{N}_2\text{O}_5$  onto saline mineral dust samples collected in southwestern USA,  
350 and similarly they found that the measured  $\varphi(\text{ClNO}_2)$  were significantly smaller than those  
351 predicted using the parameterization proposed by Bertram and Thornton (2009).

352  
 353 **Figure 7.** Measured and calculated of  $\phi(\text{ClNO}_2)$  at  $75\pm 2\%$  RH as a function of  $[\text{Cl}^-]/[\text{H}_2\text{O}_{(\text{aq})}]$ .  
 354 Black and orange curves represent  $\phi(\text{ClNO}_2)$  calculated using the BT\_09 parameterization  
 355 (Bertram and Thornton, 2009) and the Yu\_20 parameterization (Yu et al., 2020), and the associated  
 356 errors are represented by the corresponding shadows.

357  
 358 The observed discrepancies between measured and predicted  $\phi(\text{ClNO}_2)$  can be caused by  
 359 several reasons. First, even at  $\sim 75\%$  RH (the highest RH at which our experiments were conducted),  
 360 chloride contained in saline mineral dust may not be fully dissolved, and therefore our calculation  
 361 may overestimate  $[\text{Cl}^-]/[\text{H}_2\text{O}_{(\text{aq})}]$  and thus also overestimate  $\phi(\text{ClNO}_2)$ . This effect should not be  
 362 large as significant water uptake was observed at  $\sim 75\%$  RH for saline mineral dust sample we  
 363 examined (Figures 3-5). Second, perhaps more importantly, saline mineral dust samples contain  
 364 substantial amounts of insoluble minerals, and some of these minerals, such as clays, are very  
 365 reactive towards  $\text{N}_2\text{O}_5$  (Tang et al., 2017), and only nitrate but no  $\text{ClNO}_2$  was formed (Seisel et al.,  
 366 2005; Karagulian et al., 2006; Tang et al., 2012). However, the two parameterizations did not take  
 367 into account heterogeneous reaction of  $\text{N}_2\text{O}_5$  with insoluble minerals, and as a result would

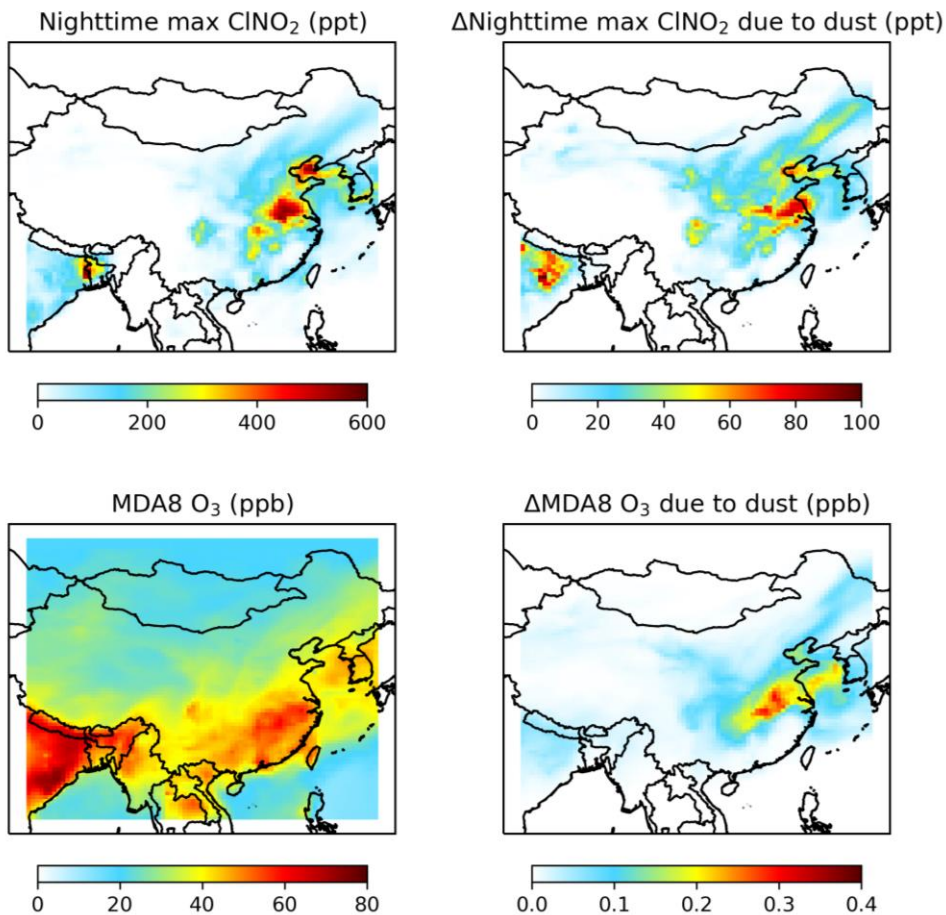

368 inevitably overestimate  $\varphi(\text{ClNO}_2)$ . At last, our calculations assumed internal mixing, but inter- and  
369 intra-particle heterogeneity of saline mineral dust particles could also contribute to the observed  
370 gap between measured and calculated  $\varphi(\text{ClNO}_2)$ . For example, a wintertime field campaign at Ann  
371 Arbor (Michigan, USA) (McNamara et al., 2020) showed that due to nonhomogeneous chloride  
372 distribution across road salt aerosol particles, observed  $\varphi(\text{ClNO}_2)$  were significantly smaller than  
373 predicted values. The comparison between measured and predicted  $\varphi(\text{ClNO}_2)$  suggested that while  
374 heterogeneous uptake of  $\text{N}_2\text{O}_5$  onto saline mineral dust could be an important source of inland  
375  $\text{ClNO}_2$ , underlying mechanisms which affect heterogeneous production of  $\text{ClNO}_2$  from saline  
376 mineral dust have not been well elucidated.

377

#### 378 **4 Atmospheric implications**

379 We consider  $\text{ClNO}_2$  formation in heterogeneous uptake of  $\text{N}_2\text{O}_5$  onto dust aerosol in GEOS-  
380 Chem to explore its **atmospheric** implications. Since  $\text{Cl}^-$  concentration in mineral dust is not well  
381 known and currently we are not able to parameterize  $\varphi(\text{ClNO}_2)$  for mineral dust (as discussed in  
382 Section 3.3), we use a fixed  $\varphi(\text{ClNO}_2)$  value of 0.1 in our simulation. This value, which is at the  
383 low end of our measured range of  $\varphi(\text{ClNO}_2)$  (<0.05 to ~0.77), is higher than those determined in  
384 our work for low chloride samples but lower than those for medium chloride samples. The purpose  
385 of our modeling work, is to preliminarily assess whether  $\text{N}_2\text{O}_5$  uptake onto saline dust may have  
386 important effects on tropospheric chemistry as a potential source of  $\text{ClNO}_2$ . We focus on  
387 simulations on 2-7 May 2017, during which a large dust event took place in East Asia. It caused  
388 high concentrations of dust aerosols with maximum hourly concentration higher than  $1000 \mu\text{g}/\text{m}^3$   
389 over a wide area in China (Zhang et al., 2018), which are also well captured by our simulations  
390 (Figure S2).

391 Figure 8 shows the weekly mean values of the nighttime maximum surface ClNO<sub>2</sub> mixing  
392 ratios and the contribution of heterogeneous reaction of N<sub>2</sub>O<sub>5</sub> with dust aerosol to ClNO<sub>2</sub> over 2-  
393 7 May 2017. The impact of N<sub>2</sub>O<sub>5</sub> uptake onto dust aerosol is calculated as the difference between  
394 the standard case in which  $\phi(\text{ClNO}_2)$  is assumed to be 0 for N<sub>2</sub>O<sub>5</sub> uptake onto dust aerosol and the  
395 case in which  $\phi(\text{ClNO}_2)$  is assumed to be 0.1. Due to large diurnal variations and near-zero mixing  
396 ratios of ClNO<sub>2</sub> in the daytime, we use the mean nighttime maximum value for ClNO<sub>2</sub>, following  
397 previous standard practice (Wang et al., 2019). The largest impact on ClNO<sub>2</sub> is found in Central  
398 China, where weekly mean nighttime maximum surface ClNO<sub>2</sub> mixing ratios are increased by 85  
399 pptv, due to heavy impact of dust aerosol transported from the north and high NO<sub>x</sub> emissions in  
400 this region. Even larger effects (up to 240 pptv increase in ClNO<sub>2</sub>) can be found on some individual  
401 days, as shown in Figures S3 and S4. These results suggest that N<sub>2</sub>O<sub>5</sub> uptake onto dust could be  
402 an important source for tropospheric ClNO<sub>2</sub> over Central and Northeast China, where ClNO<sub>2</sub>  
403 formation is conventionally believed to be limited due to relatively low aerosol chloride levels  
404 from sea salts and anthropogenic sources.

405  
 406 **Figure 8.** Modeled weekly mean mixing ratios of nighttime maximum  $\text{ClNO}_2$  (upper panels) and  
 407 maximum daily 8-h average (MDA8) ozone (bottom panels) in surface air over China during 2-7  
 408 May 2017. The left panels show simulated mixing ratios in our standard case in which  $\varphi(\text{ClNO}_2)$   
 409 is assumed to be 0 for  $\text{N}_2\text{O}_5$  uptake onto dust aerosol. The right panels show impacts of  $\text{ClNO}_2$   
 410 formation due to  $\text{N}_2\text{O}_5$  uptake onto dust, calculated as the difference between the standard case  
 411 and the case in which  $\varphi(\text{ClNO}_2)$  is assumed to be 0.1 for  $\text{N}_2\text{O}_5$  uptake onto dust.

412  
 413 Figure 8 also shows the effect of  $\text{ClNO}_2$  formation due to heterogeneous reaction of  $\text{N}_2\text{O}_5$   
 414 with dust aerosol on the daily maximum 8-h average (MDA8) ozone mixing ratios in the surface  
 415 air over China during the same period. MDA8 ozone mixing ratios are increased by up to 0.32

416 ppbv after considering mineral dust as an additional source of ClNO<sub>2</sub>. Our simulation assumes a  
417 low value of  $\varphi(\text{ClNO}_2)$  in our measured range (<0.05 to ~0.77), and is conducted in summer when  
418 ClNO<sub>2</sub> is more difficult to be accumulated due to short night (compared to winter and spring with  
419 long nights). We expect that its impacts on ClNO<sub>2</sub> and ozone could be larger for dust events in  
420 winter and spring.

421

## 422 **5 Conclusions**

423 It has been widely recognized that nitryl chloride (ClNO<sub>2</sub>), produced by heterogeneous  
424 reaction of N<sub>2</sub>O<sub>5</sub> with chloride-containing aerosols, could significantly affect atmospheric  
425 oxidation capacity. However, heterogeneous formation of tropospheric ClNO<sub>2</sub> in inland regions in  
426 China has not been well elucidated. In this work, we investigated ClNO<sub>2</sub> formation in  
427 heterogeneous reaction of N<sub>2</sub>O<sub>5</sub> with eight saline mineral dust samples collected from different  
428 regions in China as a function of RH (18-75%). Significant production of ClNO<sub>2</sub> was observed for  
429 some of the saline mineral dust samples examined, and ClNO<sub>2</sub> yields,  $\varphi(\text{ClNO}_2)$ , were determined  
430 to span from <0.05 to 0.77, depending on chemical compositions of saline mineral dust samples  
431 and RH. In general a positive dependence of  $\varphi(\text{ClNO}_2)$  on mass fractions of particulate chloride  
432 was observed at each RH, but higher particulate chloride content did not always **result in higher**  
433  $\varphi(\text{ClNO}_2)$ . On the other hand, increase in RH could increase, reduce or have no significant impacts  
434 on  $\varphi(\text{ClNO}_2)$ , revealing the complex mechanisms which drive heterogeneous uptake of N<sub>2</sub>O<sub>5</sub> onto  
435 saline mineral dust.

436 Two widely-used parameterizations (Bertram and Thornton, 2009; Yu et al., 2020) were used  
437 to estimate  $\varphi(\text{ClNO}_2)$  at 75% RH for the eight saline mineral dust samples we investigated. Both  
438 parameterizations were found to significantly overestimate the measured  $\varphi(\text{ClNO}_2)$ , and we

439 suggested that the discrepancies between measured and predicted  $\varphi(\text{ClNO}_2)$  could be due to  
440 incomplete dissolution of particulate chloride, heterogeneous reaction of  $\text{N}_2\text{O}_5$  with insoluble  
441 minerals, and/or inter- and intra-particle heterogeneity of saline mineral dust particles.

442 Assuming a  $\varphi(\text{ClNO}_2)$  value of 0.1 for heterogeneous reaction of  $\text{N}_2\text{O}_5$  with mineral dust, we  
443 use GEOS-Chem to assess the impact of this reaction on tropospheric  $\text{ClNO}_2$  and  $\text{O}_3$  in China  
444 during a severe dust event **which occurred during** 2-7 May 2017. It is found that after taking into  
445 **account**  $\text{ClNO}_2$  production due to  $\text{N}_2\text{O}_5$  uptake onto mineral dust aerosol, weekly mean nighttime  
446 maximum  $\text{ClNO}_2$  mixing ratios could be increased by up to 85 pptv during this period and the  
447 daily maximum 8-h average  $\text{O}_3$  mixing ratios were increased by up to 0.32 ppbv.

448 In summary, our work shows that heterogeneous reaction of  $\text{N}_2\text{O}_5$  with saline mineral dust  
449 can be an important source for tropospheric  $\text{ClNO}_2$  in inland China. This reaction may also **be**  
450 important for tropospheric  $\text{ClNO}_2$  production in many other regions over the world, as the  
451 occurrence of saline mineral dust aerosols has been reported in various locations, such as Iran  
452 (Gholampour et al., 2015), United States (Blank et al., 1999; Pratt et al., 2010; Jordan et al., 2015;  
453 Frie et al., 2017), and Argentina (Bucher and Stein, 2016). Currently our limited knowledge  
454 precludes quantitative prediction of heterogeneous  $\text{ClNO}_2$  production from saline mineral dust,  
455 and further investigation is thus warranted.

456

#### 457 **Appendix. $\text{N}_2\text{O}_5$ and $\text{ClNO}_2$ calibration**

458 To calibrate CIMS measurements of  $\text{N}_2\text{O}_5$ , a mixed flow containing  $\text{N}_2\text{O}_5$ , which was  
459 produced via  $\text{O}_3$  oxidation of  $\text{NO}_2$ , was sampled into the CIMS instrument, and  $\text{N}_2\text{O}_5$  was  
460 quantified using the normalized intensities of  $\text{I}(\text{N}_2\text{O}_5)^-$  clusters,  $f(\text{N}_2\text{O}_5)$ , defined as the ratio of  
461 signal intensity (cps) of  $\text{I}(\text{N}_2\text{O}_5)^-$  to that of the total reagent ions, i.e.  $\text{I}^-$  and  $\text{I}(\text{H}_2\text{O})^-$ .  $\text{N}_2\text{O}_5$

462 concentrations in the mixed flow were quantified using cavity-enhanced absorption spectroscopy  
463 (CEAS) (Wang et al., 2017a), with a detection limit of 2.7 pptv in 5 s and an uncertainty of ~25%.  
464 RH of the mixed flow was varied during the calibration in order to determine the CIMS sensitivity  
465 for  $\text{N}_2\text{O}_5$  at different RH, and the results are displayed in Figure A1. The sensitivity for  $\text{N}_2\text{O}_5$  first  
466 increased with RH, reaching the maximum value at ~40% RH, and then decreased with further  
467 increase in RH.

468  
469 **Figure A1.** CIMS sensitivities as a function of RH for (a)  $\text{N}_2\text{O}_5$  and (b)  $\text{ClNO}_2$ .

470  
471 To calibrate CIMS measurements of  $\text{ClNO}_2$ , a nitrogen flow (6 mL/min) containing 10 ppmv  
472  $\text{Cl}_2$  was passed over a slurry containing  $\text{NaNO}_2$  and  $\text{NaCl}$  to produce  $\text{ClNO}_2$  (Thaler et al., 2011),  
473 and  $\text{NaCl}$  was included in the slurry in order to minimize the formation of  $\text{NO}_2$  as a byproduct.  
474 The mixed flow containing  $\text{ClNO}_2$  was then conditioned to a given RH and sampled into the CIMS  
475 instrument; similar to  $\text{N}_2\text{O}_5$ ,  $\text{ClNO}_2$  was quantified using the normalized intensities of  $\text{I}(\text{ClNO}_2)^-$   
476 clusters,  $f(\text{ClNO}_2)$ , defined as the ratio of signal intensity (cps) of  $\text{I}(\text{ClNO}_2)^-$  to that of the total

477 reagent ions. To quantify ClNO<sub>2</sub>, the mixed flow was delivered directly into a cavity attenuated  
478 phase shift spectroscopy instrument (CAPS, Model N500, Teledyne API) to measure background  
479 NO<sub>2</sub> concentrations; after that, the mixed flow was delivered through a thermal dissociation model  
480 at 365 °C to fully decompose ClNO<sub>2</sub> to NO<sub>2</sub>, and the total NO<sub>2</sub> concentrations were then  
481 determined using CAPS. The differences in the measured NO<sub>2</sub> concentrations with and without  
482 thermal dissociation was equal to ClNO<sub>2</sub> concentrations. The CAPS instrument had a detection  
483 limit of 0.2 ppbv in 1 min for NO<sub>2</sub> and an uncertainty of ~10%. As shown in Figure A1, the  
484 sensitivity for ClNO<sub>2</sub> increased with RH up to 40%, and showed little variation with further  
485 increase in RH.
