22 **Abstract.** Characterizing the molecular composition of cloud water could provide unique insight into the aqueous chemistry.  
23 Field measurement was conducted at Mt. Tianjing in southern China during May, 2018. Thousands of formulas ( $C_{5-30}H_{4-55}O_{1-}$   
24  $_{15}N_{0-2}S_{0-2}$ ) were identified in cloud water by Fourier transform-ion cyclotron resonance mass spectrometry (FT-ICR MS).  
25 CHON represents the dominant component (43.6-65.3% of relative abundance), followed by CHO (13.8-52.1%). S-containing  
26 formulas constitute the remaining ~10-20%. Molecules have O/C of 0.45-0.56 and the double-bond equivalent of 5.10-5.70.  
27 More than 90% are assigned as aliphatic and olefinic species. No statistical difference of oxidation state is observed between  
28 cloud water and interstitial PM<sub>2.5</sub>. CHON with aromatic structures are abundant in cloud water, suggesting their enhanced in-  
29 cloud formation. Other organics in cloud water are mainly from biomass burning and oxidation of biogenic volatile organic  
30 compounds. The cloud water contains more abundant CHON and CHOS at night, which are mainly contributed by  $-N_2O_5$   
31 function and organosulfates, demonstrating the enhanced formation in dark aqueous or multi-phase reactions. While more  
32 abundant CHO are observed during the daytime, likely due to the photochemical oxidation and photolysis of N-/S-containing  
33 formulas. The results provide an improved understanding on the in-cloud aqueous-phase reactions.

34

## 35 **1 Introduction**

36 On average, approximately 70% of the Earth is covered by clouds (Stubenrauch et al., 2013; Herrmann et al., 2015). Cloud  
37 water is an important sink of organics (Herckes et al., 2013) and provides a medium for the aqueous-phase reactions of  
38 dissolved gases and aerosols (Blando and Turpin, 2000), which can substantially modify the characteristics of the organics  
39 (McNeill, 2015; Kim et al., 2019). Aqueous-phase secondary organic aerosols (aqSOA) forming in the in-cloud aqueous-phase  
40 processes significantly contribute to the total SOA with a negative impact for the visibility, human health and climate (Ge et  
41 al., 2012; Huang et al., 2018; Schurman et al., 2018; Li et al., 2020a; Smith et al., 2014; Paglione et al., 2020; Hallquist et al.,  
42 2009). Therefore, an understanding of the molecular characteristics and aqueous-phase reactions in cloud droplets is crucial to  
43 assessing their impact accurately.

44 Organics in cloud water mainly include organic acids (e.g., formic, acetic, oxalic acids and other short-chain mono and  
45 dicarboxylic acids) (Sun et al., 2016), carbonyls (e.g., formaldehyde, acetaldehyde, glyoxal and methylglyoxal) (Ervens et al.,  
46 2013; Van Pinxteren et al., 2016), as well as some heteroatom-containing compounds such as amino acids (Bianco et al.,  
47 2016b), organonitrates, and organosulfates (Zhao et al., 2013). Some less polar organics such as n-alkanes (Herckes et al.,  
48 2002), benzene, toluene, ethylbenzene and xylenes (Wang et al., 2020), polycyclic aromatic hydrocarbons (Herckes et al.,  
49 2002; Ehrenhauser et al., 2012), phenols and nitrophenols (Lüttke et al., 1997; Lüttke et al., 1999) are also observed, though  
50 with a much lower fraction of dissolved organic materials (usually < 1%). The organics that have been characterized using  
51 chromatographic and spectroscopic techniques only take a proportion of ~20% of all kinds of organics in cloud water (Herckes  
52 et al., 2013; Bianco et al., 2018). Ultra-high resolution mass spectrometry such as Fourier Transform Ion Cyclotron Resonance  
53 Mass Spectrometry (FT-ICR MS) has made possible to characterize individual molecular formulas in complex mixtures (Cho  
54 et al., 2015). In studies using ultra-high resolution MS to characterize cloud/fog water, formulas were mainly divided into  
55 CHO, CHON, CHOS and CHONS based on the elemental composition, in which CHO and CHON were usually dominant  
56 (Zhao et al., 2013; Cook et al., 2017; Brege et al., 2018; Bianco et al., 2018; Bianco et al., 2019). Boone et al. (2015) observed  
57 a high fraction of N-containing formulas in cloud water compared with particles and attributed it to the aqueous-phase  
58 formation. However, a more recent study carried out in Po Valley observed more CHO formulas in cloud water, while particle  
59 samples contained more N- and S-containing formulas. The authors attribute it to the high possibility of reactions with sulfate  
60 and nitrate ions in the concentrated environment of aerosol liquid water (Brege et al., 2018). Thus more observations are  
61 needed to provide more convincing evidences of in-cloud aqueous-phase reactions.

62 Aqueous-phase reactions have been identified as an important source of organics in cloud water in addition to the gas-liquid  
63 and particle-liquid partition. Aqueous-phase reactions mainly include radical and non-radical reactions. Under irradiation,  
64 hydroxyl radical (OH•) is the main radical in the atmosphere (Herrmann et al., 2010). In cloud water, the oxidation of  
65 precursors can be initiated by the hydrogen abstraction or electron transfer reaction driven by the OH•, resulting in the

66 formation of organic acids and condensed compounds (McNeill, 2015). On the one hand, photolysis causes the fragmentation  
67 of high-molecular-weight organic compounds, results in the formation of relatively low-molecular-weight compounds such as  
68 small acids, including oxalic, glyoxylic and, in large quantity, formic and acetic acid (Renard et al., 2015; Schurman et al.,  
69 2018; Huang et al., 2018; Sun et al., 2010; Li et al., 2014; L. Oflund et al., 2002). These compounds are highly oxygenated  
70 owing to cloud processing (Brege et al., 2018; Sareen et al., 2016), as indicated by the fact that aqSOA has a higher O/C ratio  
71 (~1) than gas-phase SOA (0.3-0.5) in the atmosphere (Ervens et al., 2011). On the other hand, photolysis also lead to the  
72 oligomerization of organics, such as pyruvic acid, phenols and methyl vinyl ketone under conditions relevant to deliquesced  
73 aerosols (Reed Harris et al., 2014; Renard et al., 2015; Yu et al., 2016). The oligomerization of tryptophan were also observed  
74 in synthetic cloud water (Bianco et al., 2016a). For the N- and S-containing organics, photochemistry may also cause the  
75 release of inorganic nitrate and sulfate (Braman et al., 2020; Laskin et al., 2015; Brüggemann et al., 2020). The main radicals  
76 in the atmosphere at night is  $\text{NO}_3^*$ , which can form from the gas-phase reaction between  $\text{NO}_2$  and  $\text{O}_3$  and enter into cloud  
77 droplets. The reactions between  $\text{NO}_3^*$  and organics lead to the oxidation of organics or the addition of functional groups  
78 containing N atoms when the aqueous phase is concentrated and acidic (Herrmann et al., 2015; McNeill, 2015; Wang et al.,  
79 2008; Szmigielski, 2016; Rudziński and Szmigielski, 2019). Meanwhile, the radical nitration is believed to form  
80 dinitroaromatics in the aqueous-phase (Kroflíc et al., 2015). Carbonyls can also react with ammonium and amine without  
81 illumination, resulting in the generation of imidazoles and N-containing oligomers, especially in aerosol liquid water and  
82 evaporating cloud water (De Haan et al., 2009; Kua et al., 2011; De Haan et al., 2011; De Haan et al., 2018). While,  
83 organosulfates are formed mainly through heterogeneous and bulk particle phase reactions (Brüggemann et al., 2020). The  
84 non-radical reactions in the aqueous phase also include hydrolysis, hydration, acid catalysis, Fenton reaction and transition  
85 metals reactivity with organics, probably ozone reactivity at the gas/liquid interface and so on (McNeill, 2015; Deguillaume  
86 et al., 2005; Herrmann et al., 2015).

87 To date, only a few studies reported the molecular characteristics of cloud water using ultra-high resolution MS, hampering  
88 our understanding of aqueous-phase reactions on the composition of cloud water. In this study, cloud water and  $\text{PM}_{2.5}$  samples  
89 at a remote mountain site were collected and analyzed by FT-ICR MS. The primary objectives of this study are to investigate  
90 the molecular characteristics and composition of the organics in cloud water, and to explore the potential influences of aqueous-  
91 phase reactions.

## 92 **2 Materials and methods**

### 93 **2.1 Sample collection**

94 A sampling campaign was carried out at an atmospheric monitoring station (112°53'56"E, 24°41'56"N, 1690 m above sea  
95 level) located in the Tianjing Mountain in southern China (Fig. S1). The site is located in a natural conservation zone far away

96 from anthropogenic activities, which is affected mainly by local biogenic emissions and long-distance transport during the  
97 monsoon seasons.

98 A Caltech Active Strand Cloudwater Collector, *Version 2* was used for cloud water collection (Demoz et al., 1996). Sampling  
99 methods are presented in [Supporting Information \(Text S1\)](#). A total of 24 cloud water samples (CL1-24) were collected in  
100 succession during a long-duration cloud event that lasted from May 8 to May 13, 2018. To investigate the molecular  
101 characteristics of the organic compounds and the effects of aqueous-phase processes, six samples collected from May 11 to  
102 May 12 (ID: CL12-17, [Table 1](#)) were selected for FT-ICR MS analysis in detail since these six samples were all collected  
103 during the maintenance stage of a cloud event with stable pH ([Table 1](#)), meteorological conditions and no dramatic change of  
104 air masses origin ([Fig. S1, S2](#)). The sampling interval of six samples are presented in [Table 1](#) and [Fig. S2](#). The samples CL12,  
105 CL13 and CL14 were collected during the daytime of May 11, while the other three samples (CL15, CL16 and CL17) could  
106 be roughly regarded as nighttime samples although the CL15 was partly collected in the evening.

107 An aerosol sampler (PM-PUF-300, Mingye Inc., China) with a cut size of 2.5  $\mu\text{m}$  was used to collect the interstitial particles  
108 ( $\text{PM}_{2.5}$ ) at a flow rate of 300  $\text{L min}^{-1}$  during the investigated cloud event. The sampling interval of  $\text{PM}_{2.5}$  was roughly 24 hours.  
109 Two  $\text{PM}_{2.5}$  samples were collected during May 11-13. The details have been provided in [Supporting Information \(Text S2\)](#).

## 110 **2.2 Sample pretreatment, instrumental analysis, and data processing**

111 Water-soluble organic compounds in cloud water were isolated using solid-phase extraction (SPE) and analyzed using an  
112 electrospray ionization (ESI) source coupled with FT-ICR MS in the negative ion mode.  $\text{PM}_{2.5}$  samples were first ultrasonically  
113 extracted with water and then pretreated and analyzed using the same methods with cloud water samples ([Text S3](#)). The details  
114 of the molecular characteristics of the two  $\text{PM}_{2.5}$  samples are beyond the scope of this study. However, we documented the  
115 main results of the  $\text{PM}_{2.5}$  samples for the contrastive analysis in the [Supporting Information \(Fig. S4, S5; Table S3, S4\)](#).  
116 Kendrick mass defects analysis was used for the formula assignment (Shi et al., 2012). The chemical formula  $\text{C}_x\text{H}_y\text{O}_z\text{N}_m\text{S}_n$ ,  
117 with molecular weight of 150-1000 Da was obtained finally. Relative abundance (RA) of each formula was represented by the  
118 intensities of each peaks after normalization by the maximum intensity in each sample. Note that ESI FT-ICR MS is not a  
119 purely quantitative technique, the intensity of the peak for each formula is a product of its concentration and ionization  
120 efficiency. However, since all of the samples were measured using the same instrumental conditions, each spectrum was biased  
121 in an equal fashion, so relative peak intensities within the acquired spectra can be compared to each other, although they cannot  
122 be related back to concentrations in the original samples (Sleighter et al., 2010; Wozniak et al., 2014).

123 The RA-weighted average elemental ratios of oxygen, carbon, and hydrogen, including  $\text{O/C}_w$  and  $\text{H/C}_w$ , the oxidation state of  
124 carbon ( $\text{OS}_{\text{C}_w}$ ), the double-bond equivalent ( $\text{DBE}_w$ ), and the modified aromaticity index ( $\text{AI}_{\text{mod}}$ ) were calculated.  $\text{OS}_{\text{C}}$ ,  $\text{DBE}$   
125 and  $\text{AI}_{\text{mod}}$  are the parameters, which are generally used to evaluate the average oxidation state of carbon atoms (Kroll et al.,  
126 2011), the degree of unsaturation of molecules (Hockaday et al., 2006), and the degree of aromaticity in molecular formulas,

127 respectively (Koch and Dittmar, 2006). The discussion in this paper is based on the weight-average values unless otherwise  
128 specified; thus, the subscript “w” is omitted for brevity in the following texts. Details of SPE pretreatment, instrumental  
129 analysis and data processing were described in [Text S3](#).

130 In addition, oxalate and water-soluble inorganic ions, and water-soluble organic nitrogen (WSON) in cloud water samples  
131 were analyzed using ion chromatograph (IC) and TOC/TN analyser. Details have been provided in [Text S3](#). The 72 h back  
132 trajectories were displayed using the Hybrid Single-Particle Lagrangian Integrated Trajectory model  
133 (<https://ready.arl.noaa.gov>) (Stein et al., 2015; Lin et al., 2017). The meteorological conditions during sampling and water-  
134 soluble ions concentrations are provided and discussed in [Text S4](#).

### 135 3. Results and Discussion

#### 136 3.1 Overview of molecular formulas of cloud water and comparison to the interstitial PM<sub>2.5</sub>

137 A total of 1691, 1546, 1604, 1264, 2364, and 2767 molecular formulas were identified in CL12-17 samples, respectively.  
138 According to the elemental compositions, four groups (CHO, CHON, CHOS and CHONS) were assigned. The reconstructed  
139 mass spectrum of a typical sample, CL12, is presented in [Fig. 1a](#). The peaks of formulas are intensive within  $m/z$  200-400. A  
140 similar pattern is also found in cloud (Zhao et al., 2013; Bianco et al., 2018; Cook et al., 2017), fog (Brege et al., 2018), and  
141 aerosols (Lin et al., 2012; Mazzoleni et al., 2012).

142 In cloud water, CHON is the most frequently observed group, representing more than 60% of the total number of assigned  
143 formulas. CHO contributes to 16.3-28.3% of the total number of identified formulas, while the proportions of S-containing  
144 formulas (CHOS and CHONS) are much lower (3.6-9.4% and 3.7-9.3%, respectively) ([Table S5](#)). RA of each group is  
145 evaluated, as shown in [Fig. 1b](#) and [Table S5](#). The fraction in RA ( $f_{RA}$ ) of the CHON group is 43.6-65.3% (54.9% on arithmetic  
146 average), and CHO contributes 13.8-52.1% (34.7% on arithmetic average). S-containing formulas constitutes the remaining  
147 fraction, approximately 10-20% ([Table S5](#)). The fraction of four groups in RA and in number are different, which is mainly  
148 attributed to some formulas with high intensities contributing much more to RA than to the number.

149 The cloud water shows distinct pattern of molecular composition with the interstitial PM<sub>2.5</sub>. In two PM<sub>2.5</sub> samples, 1198 and  
150 1057 formulas are identified, in which CHO and CHON are dominant. CHO group contributes to 39.9-49.8%, while CHON  
151 group contributes to 31.8-51.0%. The S-containing formulas constitutes the remaining fraction of 9.1-18.4%. Similar results  
152 can also be obtained by  $f_{RA}$  of CHO (44.0-55.5%), CHON (24.3-47.3%) and S-containing formulas (8.7-20.3%) ([Table S3](#)).  
153 Obviously, the molecular composition of PM<sub>2.5</sub> in this study is different from that of aerosols in the Pearl River Delta (PRD).  
154 More than a half number of all detected formulas were assigned as CHO, while CHON only accounted 8-18% in the aerosols  
155 collected at three sites in PRD (Lin et al., 2012). The higher fraction of CHON in cloud water compared with PM<sub>2.5</sub> at urban

156 and rural areas and interstitial particles is consistent with the previous finding (Boone et al., 2015), likely indicating the  
157 formation of N-containing organics in cloud water.

### 158 **3.2 Effects of cloud processing on oxidation metrics and aromaticity of the molecular formulas**

159 **Oxidation metrics** O/C and OS<sub>C</sub> are employed to evaluate the oxidation degree of molecules in cloud water. In six cloud water  
160 samples, the average O/C values range from 0.45 to 0.56 (Table S6). No significant differences of O/C are observed between  
161 cloud water and PM<sub>2.5</sub>, of which average O/C values are 0.45-0.56. In the Van Krevelen (VK) plot, CHON formulas distribute  
162 in a wide area (Fig. 2 and Fig. S6). Some of them with O/C exceeding 0.8 distribute in the top-right corner of the plots, which  
163 also result in higher O/C (0.51-0.62, Table S6) of CHON on average compared with CHO, of which O/C ratios range from  
164 0.34 to 0.46. On RA-weighted average, the O/C ratios of CHOS and CHONS range from 0.36 to 0.51 and from 0.65 to 0.88,  
165 respectively. This is not unintelligible if we note that the N and S atoms in the CHON and S-containing formulas would  
166 probably combine with O (e.g., -NO<sub>2</sub>, -NO<sub>3</sub> or -SO<sub>3</sub> function group), leading to the higher average O/C of non-CHO formulas.  
167 The OS<sub>C</sub> value excludes the influence of oxygen atoms combined with H, N, and S, thus it is a more applicative proxy to  
168 evaluate the oxidation state of carbon atoms. The average OS<sub>C</sub> values range from -0.91 to -0.72 in cloud water (Table S6),  
169 while that in PM<sub>2.5</sub> ranges from -0.84 to -0.61 (Table S4). Being limited by the sampling size, no statistical difference of OS<sub>C</sub>  
170 can be identified between cloud water and PM<sub>2.5</sub>. However, a higher OS<sub>C</sub> of detected formulas, especially CHO, appears in  
171 PM<sub>2.5</sub> samples (-0.40 in P2 sample). Similar phenomenon is also observed in CHOS. It is not consistent with the current  
172 understanding that aqueous-phase reactions generally increase the degree of oxidation (Ervens et al., 2011). However, a  
173 previous aircraft sampling also observed a lower O/C in cloud water compared with the below-cloud atmospheric particles  
174 (Boone et al., 2015), suggesting that the effects of aqueous-phase reaction may be complex in the actual atmosphere. We note  
175 that PM<sub>2.5</sub> samples were collected during the cloud event, high aerosol liquid water content in PM<sub>2.5</sub> likely provide a sink  
176 containing more concentrated precursors for the aqueous-phase reactions compared with cloud water. However, no formation  
177 mechanism of more oxidized organics in aerosol liquid water is proposed in previous studies, thus the future researches of  
178 aqueous-phase reactions in atmosphere are needed. In four groups, CHO has the highest OS<sub>C</sub> values (-0.80 ~ -0.54) (Table S6),  
179 which may be related to the high abundance of carboxyl groups in CHO.

180 To investigate the diurnal variation of oxidation metrics in cloud water, daytime and nighttime samples are compared. The  
181 O/C ratios show no identified diurnal variation expect for CHO groups. The O/C ratios and OS<sub>C</sub> of CHO collected during the  
182 daytime is slightly lower than the nighttime (Table S6), this is not consistent with the high oxidation capacity under the  
183 illumination during the daytime, indicating that the oxidation degree of the organics in cloud water is not exclusively affected  
184 by the illumination.

185 **Aromaticity** The unsaturation and aromaticity of molecular formulas could be evaluated using the H/C ratio and the DBE,  
186 where low H/C and high DBE indicate high degree of unsaturation, and to some extent, aromatic structure. On average, H/C

187 ratios in cloud water ranged from 1.44 to 1.49, with no statistic difference compared to  $PM_{2.5}$  (1.40-1.53). In the VK plot,  
188 CHOS and CHONS occupy an upper area of the diagram with high H/C ratios, indicating that they may have higher saturation  
189 compared with CHO and CHON. On average, DBE values in cloud water range from 5.10 to 5.70 (Table S6), which is  
190 generally higher than that in  $PM_{2.5}$  (4.74-5.04, Table S4). The RA-weighted DBE values of CHO, CHON, CHOS and CHONS  
191 are 4.96-6.12, 5.44-6.09, 2.72-4.58 and 3.01-4.29, respectively. DBE values are also projected onto the plots of DBE versus  
192 carbon atom number (Fig. 3). DBE values generally increase with carbon number, and CHOS and CHONS distribute in a  
193 range with low DBE values. The higher unsaturation degree of CHO and CHON is likely corresponding to the high abundance  
194 of aromatic functions.

195 Another commonly used metric of aromaticity is  $AI_{mod}$ . In cloud water, most of the formulas (94.9-98.3% of CHO, 79.2-97.5%  
196 of CHON, 93.5-98.8% of CHOS and 95.7-100.0% of CHONS in  $f_{RA}$ ) are assigned as aliphatic or olefinic compounds (Table  
197 S7). The  $f_{RA}$  of aliphatic and olefinic compounds in  $PM_{2.5}$  also exceeds 90%. The high fraction of aliphatic and olefinic and  
198 the low fraction of aromatic structure are also observed in aerosol and cloud water in previous studies (Brege et al., 2018; An  
199 et al., 2019), however, it is quite different with the primary emissions including biomass burning and coal combustion, of  
200 which the fraction of aromatic structures is higher (Song et al., 2018), indicating the aging processes of organics likely reduce  
201 the aromaticity of organics. In four groups of molecules in cloud water, CHON has the most (2.5-20.8% in  $f_{RA}$ ) aromatic  
202 structures, consistent with the high DBE values (unsaturation) of CHON. Previous studies conducted in the Po Valley, Italy  
203 (Brege et al., 2018) and Fresno, USA (Leclair et al., 2012) also observed the higher fraction of aromatics in CHON compared  
204 with the S-containing groups in fog water. The dinitrophenols in cloud water contributes to the high  $f_{RA}$  of aromatic structures  
205 in CHON significantly, which may be related to the aqueous-phase reactions (see the detailed discussion in Section 3.4).

### 206 3.3 Molecular composition of cloud water

207 **CHON** In cloud water, CHON formulas show no prominent carbon number peaks except sample CL17 (Fig. S7), and one or  
208 two nitrogen atoms are assigned to them (Fig. 4). Both the  $N_1$  and  $N_2$  categories contain 1-14 oxygen atoms. The most abundant  
209 class of  $N_1$  formulas is  $-N_1O_8$  or  $-N_1O_7$  (Fig. 4), which include  $C_{12}H_{17}NO_8$ ,  $C_{15}H_{19}NO_8$ ,  $C_{17}H_{27}NO_7$ , and  $C_8H_{11}NO_7$  and so on.  
210 More than 77.7% of the CHON formulas in  $f_{RA}$  in all six samples have O/N ratios exceeding 3, indicating that the N atoms in  
211 these molecules may be in the  $-NO_3$  functional group (Zhao et al., 2013). Samples CL12-16 show no prominent peak of the  
212 function classes in the  $N_2$  category, but a dominant peak of the  $-N_2O_5$  class is observed in CL17 (Fig. 4), where  $C_8H_8N_2O_5$  and  
213  $C_7H_6N_2O_5$  are two most abundant formulas. These formulas probably belong to dinitrophenols and their derivatives.

214 To evaluate the contribution of primary sources, we compared the molecular composition in cloud water with that in particles  
215 emitted from the primary sources such as biomass burning (including corn straw, pine branches and rice straw) and coal  
216 combustion using the same analytical instrument (Song et al., 2018). In cloud water, 40.9-51.4%, 21.9-27.1% and 48.1-59.4%  
217 (in terms of number fraction) of CHON molecules appear in the smoke particles of corn straw, pine branches and rice straw,

218 indicating a non-negligible contribution from biomass burning. While only 10.5-14.5% of molecules in cloud water can be  
219 corresponding to the coal combustion emission, suggesting the less contribution to the molecular composition of cloud water.  
220 Note that the comparison only based on the molecular formulas given by FT-ICR MS, the isomeride cannot be distinguished,  
221 thus the results only represents a possible relationship with the different sources. Additionally, some N-containing molecules  
222 are also detected in monoterpene SOA (Park et al., 2017; Zhang et al., 2018), in which the products such as  $C_7H_{9,11}NO_{7-8}$ ,  
223  $C_8H_{11}NO_{7-8}$ ,  $C_9H_{13,15}NO_{7-8}$ , and  $C_{10}H_{15,17,19}NO_{7-8}$  are detected in cloud water, indicating a contribution from monoterpene  
224 oxidation.

225 **CHO** For CHO formulas in cloud water, a prominent  $C_{17}$  peak is observed in all six samples (Fig. S7), in which the most  
226 abundant formula is  $C_{17}H_{26}O_4$ , which also causes a significant peak of  $O_4$  class (Fig. 4). The formula may belong to lipids-like  
227 compounds based on the classification in the VK plot (Bianco et al., 2018). Considering the intensive emission of biogenic  
228 volatile organic compounds (BVOCs) around the sampling site, the oxidation products of BVOCs may also contribute to the  
229 molecular composition. Putman et al. (2012) reported the molecular composition of  $\alpha$ -pinene ozonolysis SOA using FT-ICR  
230 MS. 26.9-39.1% (in term of number fraction) of the CHO formulas in cloud water are corresponding to the yields of  $\alpha$ -pinene  
231 ozonolysis, including the most abundant  $C_{17}H_{26}O_4$ , indicating possible contribution from BVOCs oxidation. In addition, cloud  
232 water contains formulas that have been observed in the combustion of coal and biogenic materials. Specifically, 26.5-38.7%,  
233 65.9-77.3%, 50.7-69.3%, and 61.1-76.7% of the CHO formulas in cloud water, by number, were detected in the smoke emitted  
234 from combustion of coal, corn straw, pine branches, and rice straw, respectively (Song et al., 2018), indicating that combustion  
235 also potentially contributes to the organics in cloud water.

236 **S-containing formulas** Most of the CHOS formulas in cloud water have  $C_{13}$  or  $C_{14}$  peaks (Fig. S7), and  $-SO_3$  or  $-SO_4$  represent  
237 the most abundant classes of CHOS (Fig. 4). We divided the CHOS formulas into two classes according to the O/S ratios:  
238  $CHOS_{O/S \geq 4}$  and  $CHOS_{O/S < 4}$ . When  $O/S \geq 4$ , CHOS can be provisionally identified as organosulfates (Lin et al., 2012). The O/S  
239 ratios of most of the CHOS formulas (78.9-95.8% in number fraction and 87.5-98.6% in  $f_{RA}$ ) in cloud water exceed 4.  
240  $CHOS_{O/S < 4}$  accounts for 1.4-12.5% in  $f_{RA}$  of all the CHOS formulas in cloud water, indicating reduced S groups exist in these  
241 formulas. Some of them are aliphatic-like, such as  $C_{24}H_{42}O_3S$ ,  $C_{29}H_{52}O_3S$ . Some are aromatic-like with high DBE values, such  
242 as  $C_6H_6O_3S$ , which may be an aromatic ring bearing a  $-SO_3H$  group. Some of them may have more than one aromatic rings,  
243 such as  $C_{17}H_{16}O_3S$ ,  $C_{20}H_{18}O_3S$ . Note that the aromaticity of these formulas cannot be identified accurately using  $AI_{mod}$  values,  
244 since the value is a conservative method to evaluate the aromaticity (Koch and Dittmar, 2006). The presence of aromatic  
245 structure in these molecules indicates that they are likely emitted by anthropogenic sources or biomass burning (Ervens et al.,  
246 2011). Most of the CHONS formulas clearly peak at  $C_{10}$  (Fig. S7) and have more than seven O atoms (Fig. 4), allowing the  
247 presence of both sulfate and nitrate functional groups. These species can be nitrooxy organosulfates, which have been widely  
248 observed in the cloud/fog water (Zhao et al., 2013; Brege et al., 2018) and aerosols (Wozniak et al., 2014). For the detected S-

249 containing formulas in cloud water, 6.2-23.0%, 15.9-33.6% and 15.0-34.3% in terms of number fraction are corresponding to  
250 the molecules in particles emitted by burning of corn straw, pine branches, and rice straw, respectively, while 24.8-47.7%  
251 (41.0% on arithmetic mean) are corresponding to that in coal combustion (Song et al., 2018), indicating coal combustion  
252 contributes to S-containing formulas in cloud water more significantly compared with that to CHO and CHON.

### 253 **3.4 Organic matter formed by in-cloud aqueous-phase reactions**

#### 254 **3.4.1 Formation of dinitrophenols**

255 To investigate the formation of molecules in cloud water, we compared the molecular formulas in cloud water with PM<sub>2.5</sub>. For  
256 CHON, the -N<sub>1</sub>O<sub>8</sub> or -N<sub>1</sub>O<sub>7</sub> formulas are also abundant in PM<sub>2.5</sub> samples (Fig. S5), suggesting that these formulas may not  
257 only form in cloud water. However, the formulas with high intensities, e.g., C<sub>8</sub>H<sub>8</sub>N<sub>2</sub>O<sub>5</sub>, C<sub>7</sub>H<sub>7</sub>N<sub>2</sub>O<sub>5</sub> and C<sub>6</sub>H<sub>4</sub>N<sub>2</sub>O<sub>5</sub> in cloud  
258 water are not detected in PM<sub>2.5</sub> samples. Earlier studies have found that over one-third of the nitrophenols and the majority of  
259 the dinitrophenols are contributed by secondary formation (Harrison et al., 2005). The transforming from 2-nitrophenol into  
260 2,4-dinitrophenol was also observed during cloud events (Lüttke et al., 1997; Lüttke et al., 1999). Aqueous-phase radical  
261 nitration of mononitroaromatics has been reported to be a potential pathway to form dinitroaromatics (Lüttke et al., 1999;  
262 Kroflic et al., 2015; Cook et al., 2017). This implies that in-cloud aqueous-phase reactions represent the main formation  
263 pathway of dinitrophenols at the observation site.

264 Generally, CHON in cloud water has a higher  $f_{RA}$  during the nighttime (56.2-65.3%) compared with the daytime (43.6-54.9%)  
265 (Table S5), which is consistent with the previous findings for aerosols (O'Brien et al., 2014). Particularly, the RA of -N<sub>2</sub>O<sub>5</sub>  
266 formulas increases significantly at night. The representative formulas including C<sub>6</sub>H<sub>4</sub>N<sub>2</sub>O<sub>5</sub>, C<sub>7</sub>H<sub>6</sub>N<sub>2</sub>O<sub>5</sub>, and C<sub>8</sub>H<sub>8</sub>N<sub>2</sub>O<sub>5</sub> account  
267 for 0.5%, 0.1%, 0.4%, 0.7%, 2.1%, and 14.8% of CHON in  $f_{RA}$  for samples CL12-17, respectively. This may attribute to the  
268 aqueous-phase formation of these possible dinitrophenols at night. While during the daytime, the direct photolysis of  
269 nitrophenols would release NO<sub>2</sub><sup>-</sup> and NO<sub>3</sub><sup>-</sup> (Harrison et al., 2005; Chen et al., 2005; Bejan et al., 2006), causing the observed  
270 low RA of nitrophenols and dinitrophenols. Consistently, the five diurnal-nocturnal cycle samples (CL2-23) exhibit a higher  
271 concentration of WSON at night compared with the daytime (Text S5, Fig. S3 and Table S2). A recent study conducted at the  
272 Field Museum Tama Hill, Japan also observed that aerosol liquid water accelerated the formation of WSON, especially at  
273 night, and the authors suggested that aqueous-phase reactions between NH<sub>4</sub><sup>+</sup>/reactive nitrogen and BVOCs at night contribute  
274 significantly to WSON in particles (Xu et al., 2020). While in this study, the elevated abundance of N-containing organics in  
275 cloud water at night are mainly contributed by dinitrophenols and their derivatives, which are the products of radical nitration  
276 in the aqueous phase, indicating a possible pathway for the generation of WSON.

### 277 3.4.2 Formation of oxygenated organic matter and organosulfates

278 For CHO, the most abundant  $C_{17}H_{26}O_4$  in cloud water is not detected in the  $PM_{2.5}$  samples, suggesting a formation by the in-  
279 cloud aqueous-phase reactions, although the contribution from BVOCs cannot be ruled out. Interestingly, CHO formulas in  
280  $PM_{2.5}$  samples peak at  $O_8$  (Fig. S5), which is significantly higher than cloud water (Fig. 4). This is consistent with the higher  
281  $OS_C$  values appear in  $PM_{2.5}$  samples. Some highly oxidized molecules (HOMs,  $O/C \geq 0.6$ ), e.g.,  $C_7H_{10}O_5$ ,  $C_8H_{12}O_5$ ,  $C_{13}H_{24}O_{13}$ ,  
282 are identified in cloud water, however, the HOMs in cloud water only account for 12.6-32.2% in terms of  $f_{RA}$ . A higher  $f_{RA}$  of  
283 CHO is observed during the daytime (Fig. 1b), which may result from the photochemical oxidation (e.g., the oxidation of  
284 volatile organic compounds, VOCs) (Ehn et al., 2014; Wang et al., 2017) and photolysis of N- and S-containing formulas in  
285 cloud water under the illumination (Bruggemann et al., 2020; Laskin et al., 2015).

286 For CHOS formulas, the most abundant functions classes are similar between cloud water and  $PM_{2.5}$ , and no identifiable  
287 difference of fraction of organosulfates is observed between cloud water and  $PM_{2.5}$ , which may indicate the multiphase  
288 reactions and/or other common sources of CHOS in cloud water and  $PM_{2.5}$ . However, S-containing formulas are abundant at  
289 night (8.4-20.9% in  $f_{RA}$ ) compared with daytime (4.3-10.2% in  $f_{RA}$ ). We note that the  $f_{RA}$  of  $CHOS_{O/S \geq 4}$  at night (92.9-98.6%)  
290 is slightly higher than that during the daytime (87.5-92.2%). Thus the formation of organosulfates likely enhances at night,  
291 while the photochemical oxidation of organosulfates results in the release of inorganic sulfate during the daytime (Bruggemann  
292 et al., 2020), causing a low fraction of organosulfates.

### 293 4 Conclusions and Atmospheric Implications

294 This study investigated the molecular characteristics of cloud water using FT-ICR MS. Thousands of formulas including CHO,  
295 CHON, CHOS and CHONS were detected, in which CHON and CHO formulas are dominant. Although here we only include  
296 one single diurnal cycle, and the contingency cannot be ruled out, this study highlights the important effects of in-cloud  
297 aqueous-phase reactions on the molecular characteristics and composition of cloud water.

298 Previous studies expected a higher oxidation state of organics in cloud water, however, no statistically difference between  
299 cloud water and  $PM_{2.5}$  is observed in this study. While a higher  $OS_C$  of detected formulas, especially CHO, appears in  $PM_{2.5}$   
300 samples. Most of formulas are identified as aliphatic and olefinic species, CHON and their aromatic structures are abundant  
301 in cloud water. The complexity of aqueous-phase processes in the actual atmosphere appeal to the future researches.

302 Our results showed that N-containing formulas are the most abundant formulas in cloud water, which may relate to the  
303 aqueous-phase formation. Dinitrophenols and derivatives exist abundantly in cloud water, especially at night, suggesting the  
304 contribution on N-containing organics from radical nitration in cloud water. Meanwhile, organosulfates are also abundant in  
305 cloud water, and a slightly higher fraction is observed at night, suggesting the dark-reaction formation. Nitroaromatic  
306 compounds have been identified as one of the major light absorption components in brown carbon (Li et al., 2020b) and

307 regarded as the phytotoxin as well as suspected carcinogenic materials (Harrison et al., 2005). Organosulfates are thought to  
308 affect the physicochemical properties of aerosol such as hygroscopicity and cloud condensation nuclei formation potential  
309 (Bruggemann et al., 2020). Thus the aqueous-phase formation of N-containing organics and organosulfates at night are worth  
310 targeting in the near future.

311

312

313 *Supplement.* Supporting information includes five texts ([Text S1-S5](#)), seven figures ([Fig. S1-S7](#)) and seven tables ([Table S1-](#)  
314 [S7](#)) related to the manuscript.

315

316 *Data availability.* The raw data of this study can be obtained by contacting the corresponding author.

317

318 *Author contributions.* XB and GZ design the research with input from XW, PP and GS. YF, FJ and YY collected samples. WS,  
319 BJ carried out the sample pretreatment and instrumental analysis under the guidance of YL. WS processed data when YF and  
320 XL gave constructive discussion. WS wrote the manuscript, and XB, GZ and YF interpreted data and edited the manuscript.  
321 JC, DC, and JO had an active role in supporting the sampling work. All authors contributed to the discussions of the results  
322 and refinement of the manuscript.

323

324 *Competing interests.* The authors declare that they have no conflict of interest.

325

326 *Acknowledgements.* The authors gratefully acknowledge Jianzhong Song and Chunlin Zou (Guangzhou Institute of  
327 Geochemistry, Chinese Academy of Sciences) for the guidance and assistance during sample pretreatment and providing the  
328 raw data related to the article *Song et al., 2018*, which is helpful to the discussion of this manuscript.

329

330 *Financial support.* This work was supported by National Nature Science Foundation of China (41877307 and 42077322),  
331 Natural Science Foundation of Guangdong Province (2019B151502022), and Guangdong Foundation for Program of Science  
332 and Technology Research (2019B121202002 and 2019B121205006).
