18 **Abstract**

19 After a continuous increase in surface ozone (O_3) level from 2013 to 2019, the overall
20 summertime O_3 concentrations across China showed a significant reduction in 2020. In contrast to
21 this overall reduction in surface O_3 across China, unexpected surface O_3 enhancements of $10.2 \pm$
22 0.8 ppbv (23.4%) were observed in May-June 2020 vs. 2019 over the Sichuan basin (SCB), China.
23 In this study, we use high resolution nested-grid GEOS-Chem simulation, the eXtreme Gradient
24 Boosting (XGBoost) machine learning method, and the exposure-response relationship to
25 determine the drivers and evaluate the health risks of the unexpected surface O_3 enhancements. We
26 first use the XGBoost machine learning method to correct the GEOS-Chem model-to-measurement
27 O_3 discrepancy over the SCB. The relative contributions of meteorology and anthropogenic
28 emissions changes to the unexpected surface O_3 enhancements are then quantified with the
29 combination of GEOS-Chem and XGBoost models. In order to assess the health risks caused by the
30 unexpected O_3 enhancements over the SCB, total premature death mortalities are estimated. The
31 results show that changes in anthropogenic emissions caused 0.9 ± 0.1 ppbv of O_3 reduction and
32 changes in meteorology caused 11.1 ± 0.7 ppbv of O_3 increase in May-June 2020 vs. 2019. The
33 meteorology-induced surface O_3 increase is mainly attributed to an increase in temperature and the
34 decreases in precipitation, specific humidity and cloud fractions over the SCB and surrounding
35 regions in May-June 2020 vs. 2019. These changes in meteorology combined with the complex
36 basin effect enhance biogenic emissions of volatile organic compounds (VOCs) and nitrogen oxides
37 (NO_x), speed up O_3 chemical production, and inhibit the ventilation of O_3 and its precursors, and
38 therefore account for the surface O_3 enhancements over the SCB. The total premature mortality due
39 to the unexpected surface O_3 enhancements over the SCB has increased by 89.8% in May-June 2020
40 vs. 2019.

1 Keywords: Ozone; Health risk; Emissions; Meteorology; Chemical model; Machine learning

2 **1. Introduction**

3 Surface ozone (O_3) is largely generated from its local anthropogenic (fossil fuel and biofuel
4 combustions) and natural (biomass burning (BB), lightning, and biogenic emissions) precursors
5 such as volatile organic compounds (VOCs), nitrogen oxides (NO_x), and carbon monoxide (CO) via
6 a chain of photochemical reactions (Cooper, 2019;Sun et al., 2018). Additional portion of surface
7 O_3 is transported from long-distance regions or from stratosphere (Akimoto et al., 2015;Wang et al.,
8 2020b). Surface O_3 is one of the most harmful air pollutants that threatens human health and corps
9 production (Fleming et al., 2018;Lu et al., 2020;Sun et al., 2018;Van Dingenen et al., 2009).
10 Exposure to ambient O_3 pollution evokes a series of health risks including stroke, respiratory disease
11 (RD), hypertension, cardiovascular disease (CVD), and chronic obstructive pulmonary disease
12 (COPD) (Brauer et al., 2016;Lelieveld et al., 2013;Li et al., 2015;Liu et al., 2018;Lu et al.,
13 2020;Wang et al., 2020c). Lu et al., 2020 estimated that the premature RD mortalities attributable
14 to ambient O_3 exposure in 69 Chinese cities in 2019 reached up to 64,370.

15 Surface O_3 variability is sensitive to both emissions and meteorological changes (Liu and Wang,
16 2020a, b;Lu et al., 2019c). Meteorological conditions affect surface O_3 variability indirectly through
17 changes in natural emissions of its precursors or directly via changes in wet and dry removal,
18 dilution, chemical reaction rates, and transport flux (Li et al., 2019a;Lin et al., 2008;Liu and Wang,
19 2020a;Lu et al., 2019d). A reduction in temperature can lessen O_3 production by slowing down the
20 chemical reaction rates (Fu et al., 2015;Lee et al., 2014;Liu and Wang, 2020a) or reducing the
21 biogenic VOCs and NO_x emissions (Guenther et al., 2006;Im et al., 2011;Tarvainen et al., 2005). A
22 dryer meteorological condition can result in an increase in surface O_3 level (He et al.,
23 2017;Kalabokas et al., 2015;Liu and Wang, 2020a). Depending on which process dominates the
24 influence of planetary boundary layer height (PBLH) on surface pollutants, a higher PBLH can
25 either reduce surface O_3 level by diluting O_3 and its precursors into a larger volume of air (Sanchez-
26 Ccoyollo et al., 2006;Wang et al., 2020d) or increase surface O_3 level by transporting more O_3 from
27 upper troposphere or lessening NO abundance for O_3 titration (He et al., 2017;Liu and Wang,
28 2020a;Sun et al., 2009). Precipitation has been verified to decrease surface O_3 level through the wet
29 removal of its precursors, and clouds reduce surface O_3 level by decreasing the oxidative capacity
30 of the atmosphere and enhancing scavenging of atmospheric oxidants (Lelieveld and Crutzen,
31 1990;Liu and Wang, 2020b;Shan et al., 2008;Steinfeld, 1998). A higher wind speed can decrease
32 surface O_3 level by a fast ventilation of O_3 and its precursors (Lu et al., 2019c;Sanchez-Ccoyollo et
33 al., 2006).

34 Emissions of air pollutants affect surface O_3 variability by perturbing the abundances of
35 hydroperoxyl (HO_2) and alkylperoxyl (RO_2) radicals which are the key atmospheric constituents in
36 formation of O_3 (Liu and Wang, 2020b). Many previous studies have verified a nonlinear
37 relationship between O_3 and its precursors (e.g., (Atkinson, 2000;Liu and Wang, 2020b;Lu et al.,
38 2019d;Sun et al., 2018;Wang et al., 2017). If surface O_3 formation regime lies within the VOCs
39 limited region, reductions in VOCs emissions will result in a reduction in surface O_3 level. Similarly,
40 if surface O_3 formation regime lies within the NO_x limited region, reductions in NO_x emissions will
41 result in a reduction in surface O_3 level (Atkinson, 2000;Wang et al., 2017). If surface O_3 formation
42 regime lies within transitional region, reductions in either VOC or NO_x emissions will result in a

1 reduction in surface O₃ level. Atmospheric aerosols can affect surface O₃ level through either
2 heterogeneous reactions of reactive gases (Li et al., 2018;Lou et al., 2014;Lu et al., 2012;Stadtler et
3 al., 2018) or affecting the solar radiation for gases photolysis and oxidation (Li et al., 2011;Lu et al.,
4 2019c;Lu et al., 2019d;Xing et al., 2017).

5 Understanding the drivers of surface O₃ variability has a strong implication for O₃ mitigation
6 purpose (Chen et al., 2020;Lu et al., 2019c;Sun et al., 2018). China has experienced a continuous
7 increase in surface O₃ level despite the implementation of control measures on NO_x since 2013 (Liu
8 and Wang, 2020a, b;Lu et al., 2018;Lu et al., 2020). Many studies have attempted to determine the
9 drivers of high-O₃ events occurred in specific region and time across China. Most of these studies
10 focus on the most densely populated and highly industrialized areas in eastern China, whereas the
11 studies in the rest part of China are still limited (Liu and Wang, 2020a, b;Lu et al., 2019a;Lu et al.,
12 2019b;Lu et al., 2012;Wang et al., 2020a;Wang and Lu, 2019;Wang et al., 2017). As China has a
13 vast territory with a wide range of emission levels and meteorological conditions, O₃ variability and
14 its drivers may vary both temporally and geographically, so the results from one region are not likely
15 to be applied nationally. In addition, previous studies typically use state-of-the-art chemical
16 transport models (CTMs) with sensitivity simulations to quantify the drivers of O₃ variability, e.g.,
17 fixed meteorology but varied emission levels to quantify the influences of emission changes or vice
18 versa (Liu and Wang, 2020a, b;Lu et al., 2019a). However, uncertainties in local meteorological
19 fields, emission estimates, and model mechanisms can lead to a discrepancy in CTMs that may
20 affect the accuracy of O₃ predictions and their sensitivities to changes in emissions and meteorology
21 (Lu et al., 2019c;Young et al., 2018). This is in particular for the Sichuan basin (SCB), one of the
22 most industrialized and populated cities cluster in western China, where large discrepancies between
23 measured and modelled surface O₃ are found due to the complex terrain (Lu et al., 2019c;Wang et
24 al., 2020d).

25 After a continuous increase in surface O₃ level from 2013 to 2019, the summertime (May–
26 August) O₃ concentration across China showed a significant reduction in 2020 (Figure 1 (d)). In this
27 study, we use high resolution nested-grid GEOS-Chem simulation, the eXtreme Gradient Boosting
28 (XGBoost) machine learning method, and the exposure–response relationship to determine the
29 drivers and evaluate the health risks of the unexpected surface O₃ enhancements. We first use the
30 XGBoost machine learning method to correct the GEOS-Chem model-to-measurement O₃
31 discrepancy over the SCB. The relative contributions of meteorology and anthropogenic emissions
32 changes to the unexpected surface O₃ enhancements are then quantified with the combination of
33 GEOS-Chem and XGBoost models. In order to assess the health risks caused by the unexpected O₃
34 enhancements over the SCB, total premature death mortalities are also estimated.

35 **2. Methods and data**

36 **2.1 Surface O₃ data and auxiliary data over the SCB**

37 China has identified nine city clusters that lead the populations and developments of economy,
38 society, and culture across China. The SCB contains the fourth-largest cities cluster in China after
39 the Yangtze River Delta (YRD), the Pearl River Delta (PRD), and the Beijing-Tianjin-Hebei (BTH)
40 cities clusters. The location of the SCB city cluster is shown in Figure S1. With Chongqing and
41 Chengdu as the dual core cities, more than a dozen cities including Mianyang, Deyang, Yibin,
42 Nanchong, Dazhou, and Luzhou over the SCB have achieved rapid economic development and

1 industrial upgrading. As the region with the strongest economic strength and best economic
2 foundation in western China, the SCB region has many industries such as energy and chemical
3 industry, electronic information, food processing, equipment manufacturing, eco-tourism, and
4 modern finance. As one of the most densely populated and highly industrialized regions in China
5 combined with the basin terrain which is favorable to the accumulation of air pollutants, the SCB is
6 a newly emerging region of severe air pollution in China (Lu et al., 2019b;Lu et al., 2012).

7 Surface O₃ measurements over the SCB are available from the China National Environmental
8 Monitoring Center (CNEMC) network (<http://www.cnemc.cn/en/>, last access: 2 July 2021). The
9 CNEMC network has routinely measured the concentrations of CO, O₃, NO₂, SO₂, PM₁₀, and PM_{2.5}
10 at 122 sites in 22 key cities over the SCB since 2015. The mean geolocation, population, the number
11 of measurement site, and data range of each city are summarized in Table 1. The altitude of these
12 cities ranges from 0.3 to 4.3 km (above sea level, a.s.l.) and the population ranges from 822 to
13 32,054 thousand. The number of measurement site in each city ranges from 2 to 21. Surface O₃
14 measurements at all measurement sites are based on similar differential absorption ultraviolet (UV)
15 analyzers. The hourly mean time series of surface O₃ concentrations have covered the period from
16 January 2015 to present at all measurement sites in the 22 cities. After removing unreliable
17 measurements with the filter criteria used in (Lu et al., 2020) (Section S1), we average the O₃
18 concentrations at all measurement sites in each city to form a city representative O₃ dataset. O₃
19 metric used in this study is on maximum 8-h average (MDA8) basis.

20 Since the vertical distributions of tropospheric HCHO and NO₂ are weighted heavily toward
21 the lower troposphere over polluted regions, many studies have used tropospheric column
22 measurements of these gases to represent near-ground conditions (Streets et al., 2013;Sun et al.,
23 2021b;Sun et al., 2018). In this study, the tropospheric NO₂ and HCHO columns from the
24 TROPOMI Level 3 products are used for investigating the changes in O₃ precursors in May-June
25 2020 vs. 2019. TROPOMI overpasses China at approximately 13:30 local time (LT) with a ground
26 pixel size of 7 km × 7 km. Pixels with quality assurance values of less than 50% for HCHO and 75%
27 for NO₂ are not included in present work.

28 **2.2 GEOS-Chem nested-grid simulation**

29 We use the high resolution nested-grid GEOS-Chem model version 12.2.1 to simulate surface
30 O₃ over the SCB (Bey et al., 2001). Simulations are conducted at a horizontal resolution of 0.25 ° ×
31 0.3125 ° over the nested domain (70 °–140 °E, 15 °–55 °N) covering China and surrounding regions.
32 The boundary conditions for the nested-grid GEOS-Chem simulation are archived from the global
33 simulation at 2 ° × 2.5 ° resolution (Sun et al., 2021a;Sun et al., 2021b;Yin et al., 2020;Yin et al.,
34 2019) We spun up the model for one year to remove the influence of the initial conditions. We first
35 run global simulation at 2 ° × 2.5 ° resolution and then interpolate the restart file on 1 January 2018
36 into high resolution (0.25 ° × 0.3125 °) for the nested domain to initialize the nested model simulation
37 from January 2019 to June 2020.

38 The simulations were driven by GEOS-FP meteorological field at the native resolution of 0.25 °
39 × 0.3125 ° and 47 layers from surface to 0.01 hPa at the top. The PBLH and surface meteorological
40 variables are implemented in 1-hour interval and other meteorological variables are in 3-hour
41 intervals. The time step applied in the model for transport is 5 minutes and for chemistry and
42 emissions is 10 minutes (Philip et al., 2016) The non-local scheme for the boundary layer mixing

1 process is from (Lin and McElroy, 2010), wet deposition is from (Liu et al., 2001), and dry
2 deposition is generated with the resistance-in-series algorithm (Wesely, 1989; Zhang et al., 2001).
3 The photolysis rates are from the FAST-JX v7.0 photolysis scheme (Bian and Prather, 2002).
4 Chemical mechanism follows the universal tropospheric-stratospheric Chemistry (UCX)
5 mechanism (Eastham et al., 2014). The GEOS-Chem simulation outputs 47 layers of O₃ and other
6 atmospheric constituents over China with a temporal resolution of 1 hour.

7 We use the Community Emissions Data System (CEDS) inventory for global anthropogenic
8 emissions at the latest 2017 level, which is overwritten by the Chinese anthropogenic emissions
9 with the Multi-resolution Emission Inventory (MEIC) in 2019 (Hoesly et al., 2018; Li et al.,
10 2017; McDuffie et al., 2020; Zheng et al., 2018). Anthropogenic emissions are fixed for 2019 and
11 2020. Global BB and biogenic emissions were from the Global Fire Emissions Database (GFED v4)
12 inventory (Giglio et al., 2013) and the Model of Emissions of Gases and Aerosols from Nature
13 (MEGAN version 2.1) inventory (Guenther et al., 2012), respectively. Soil NO_x emissions (Hudman
14 et al., 2010; Lu et al., 2021) and lightning NO_x (Murray et al., 2012) emissions are calculated online
15 in the model.

16 2.3 Correction of GEOS-Chem discrepancy with machine learning method

17 We used the XGBoost machine learning method to correct the GEOS-Chem model-to-
18 measurement O₃ discrepancy over the SCB following (Keller et al., 2021). The same methodology
19 has also been applied in our companion study examining ozone changes over the eastern China from
20 2019 to 2020 (Yin et al., 2021). It uses the Gradient Boosting Decision Tree (GBDT) framework to
21 iteratively train the GEOS-Chem model-to-measurement discrepancy to improve the model
22 predictions in a stagewise manner. XGBoost method minimizes the loss function by adding a weak
23 learner for the purpose of optimizing the objective function. The optimization objective function
24 used in XGBoost model is expressed as,

$$25 L^{(t)} \simeq \sum_{i=1}^n [l(y_i, \hat{y}^{(t-1)}) + g_i f_t(x_i) + \frac{1}{2} h_i f_t^2(x_i)] + \Omega(f_t) \quad (1)$$

$$26 g_i = \partial_{\hat{y}^{(t-1)}} l(y_i, \hat{y}^{(t-1)}) \quad (2)$$

$$27 h_i = \partial_{\hat{y}^{(t-1)}}^2 l(y_i, \hat{y}^{(t-1)}) \quad (3)$$

28 where g_i and h_i are first and second order gradients of the loss function, respectively. $L^{(t)}$
29 represents the optimization objective function to be solved at the t -th iteration. $l(y_i, \hat{y}^{(t-1)})$ is the
30 loss function representing the difference between the prediction for the i -th sample at the $(t-1)$ -th
31 iteration and the real values y_i . Function $f(t)$ is the amount of change at the t -th iteration. Overall,
32 the objective function consists of a two-order Taylor approximation expansion of the loss function
33 and the regularization term ($\Omega(f_t)$), which penalizes the complexity of the model and prevents
34 overfitting of the model. Compared to traditional GBDT method, XGBoost method has the
35 following advantages: (1) effectively handles missing values; (2) prevents overfitting; (3) reduces
36 computing time by using parallel and distributed computing methods.

37 Since GEOS-Chem model-to-measurement discrepancy is usually site-specific, we train a
38 separate XGBoost model for each site. Similar to the method of (Keller et al., 2021), we use a full
39 seasonal cycle of hourly measurements in 2019 at each site as the learning samples, and GEOS-

1 Chem input of emissions and meteorological parameters, output concentrations of atmospheric
2 constituents, and time information as training input data. In order to incorporate emissions and
3 meteorological factors that affect O_3 production properly, we have included the GEOS-Chem
4 simulated concentrations of 43 atmospheric chemical constituents, emissions of 21 atmospheric
5 chemical constituents, 10 meteorological parameters, and 4-time parameters (e.g., hour, day, month,
6 and year) into the data training. All these training input data are summarized in Table S1 and have
7 been standardized as equation (2) in section S2. We choose a learning rate of 0.35, maximum tree
8 depth of 6, L1 and L2 regularization terms of 0 and 1, the loss function of mean square, and
9 evaluation metric of root-mean-square error (RMSE) in the data training.

10 We use k -fold cross-validation method to test the performance of the XGBoost model ($k=1 - n$). First, all sample data are randomly and uniformly divided into k groups, where one group is
11 taken as the test dataset and the remaining $k-1$ groups are taken as the training dataset. We then start
12 to train the model and use the test dataset to evaluate the performance of the trained model. We
13 repeated this process for k times by using different groups of datasets as the test data. The training
14 model is finally determined if all the k groups of experiments show similar performances. This
15 method ensures the stability and robustness of XGBoost model and avoid overfitting. In this study,
16 a 10-fold cross-validation method is applied, i.e., we divide the O_3 measurements in 2019 into 10
17 groups of sub data: the training dataset accounts for 90% and the test dataset accounts for the
18 remaining 10% of the total sample data. We also attempted to use 60% and 80% of the sample data
19 as the training dataset and do not find significant influences on the results, indicating the robustness
20 of the XGBoost training model.
21

22 **2.4 Quantifying meteorological and emissions contributions**

23 We have used the GEOS-Chem only and the combination of GEOS-Chem and XGBoost model
24 (hereafter GEOS-Chem-XGBoost) to quantify the contributions of meteorology and anthropogenic
25 emissions to the unexpected surface O_3 enhancements over the SCB in 2020, following (Yin et al.,
26 2021). For the GEOS-Chem method, since the anthropogenic emissions are fixed, the simulated O_3
27 differences between 2020 and 2019 can be attributed to changes in meteorological conditions, which
28 is calculated as,

$$29 \quad G_{Met} = G_{2020} - G_{2019} \quad (4)$$

30 The contribution of anthropogenic emissions changes can then be quantified as,

$$31 \quad G_{Emis} = (Meas_{2020} - Meas_{2019}) - G_{Met} \quad (5)$$

32 where G_{Met} and G_{Emis} represent the meteorology and anthropogenic emissions contributions,
33 respectively. $Meas_{2019}$ and $Meas_{2020}$ represent O_3 measurements in 2019 and 2020, respectively.
34 G_{2019} and G_{2020} represent GEOS-Chem O_3 simulations in 2019 and 2020, respectively.

35 Since the GEOS-Chem-XGBoost model has corrected the GEOS-Chem model-to-
36 measurement discrepancy in 2019, we assume it can provide accurate predictions to the surface O_3
37 measurements in 2020 if the anthropogenic emissions were unchanged. This assumption is valid
38 since the probability density functions (PDFs) of key O_3 precursors and meteorological parameters
39 for the training data within a full seasonal cycle of 2019 cover the variation ranges of these factors
40 in May-June 2020 (Figures S2 and S3). For predicting O_3 evolutions in 2020, all input parameters
41 except anthropogenic emissions fed into each GEOS-Chem-XGBoost model are updated to match
42 the measurements in 2020, while anthropogenic emissions are fixed at the 2019 levels. As a result,

1 the differences between the GEOS-Chem-XGBoost predictions for 2020 and the 2020
 2 measurements are attributed to the changes in anthropogenic emissions (equation (6)). The
 3 meteorology induced contributions are then obtained as equation (7) by subtracting the
 4 anthropogenic emissions induced contributions.

5 $XG_Emis = Meas_{2020} - XG_{2020}$ (6)

6 $XG_Met = (Meas_{2020} - Meas_{2019}) - XG_Emis$ (7)

7 where the acronyms are similar to those in equations (4) and (5) but for GEOS-Chem-XGBoost
 8 method. By correcting the model-to-measurement discrepancy, GEOS-Chem-XGBoost model is
 9 expected to provide a more accurate O_3 sensitivity to changes in both meteorology and
 10 anthropogenic emissions as will be discussed later.

11 2.5 Health risks evaluation

12 We have assessed the total premature mortalities including all nonaccidental causes,
 13 hypertension, CVD, RD, COPD, and stroke attributed to ambient O_3 exposure in all cities over the
 14 SCB in 2019 and 2020. We first calculated the O_3 induced daily premature mortalities based on the
 15 exposure-response relationship described in Cohen et al., 2004, which have been used in many
 16 subsequent studies (Anenberg et al., 2010; Liu et al., 2018; Wang et al., 2021). We then added up the
 17 daily premature mortalities within May-June or the whole year to get the total O_3 induced premature
 18 mortalities in the respective periods. The population data used in this study include all age groups,
 19 which may result in higher daily mortalities than expected (Liu et al., 2018; Wang et al., 2021).
 20 According to (Cohen et al., 2004), the daily premature mortalities attributable to ambient O_3
 21 exposure can be estimated by the following equation (Cohen et al., 2004),

$$\Delta x = \begin{cases} 0, & \text{if } C_{meas} - C_{thres} \leq 0 \\ C_{meas} - C_{thres}, & \text{if } C_{meas} - C_{thres} \geq 0 \end{cases} \quad (8)$$

$$\Delta M = y_0 [1 - \exp(-\beta \Delta x)] \times Pop \quad (9)$$

22 where ΔM represents the daily premature mortalities due to ambient O_3 exposure. The city
 23 representative daily mean O_3 concentration C_{meas} is an average of all measurements in each city.
 24 Variable y_0 is the daily baseline mortality rate for each disease averaged from all ages and genders.
 25 We follow the method of (Wang et al., 2021) and use the daily y_0 value for each disease from the
 26 latest China Health Statistical Yearbook in 2018. β represents the increase in daily mortality as a
 27 result of each $10 \mu\text{g}/\text{cm}^3$ ($\sim 5.1 \text{ ppbv}$) increase in daily O_3 concentration, which is often referred to
 28 as the concentration response function (CRF) in previous studies. We collected the CRF values from
 29 those used in (Yin et al., 2017) and (Wang et al., 2021). Δx represents the incremental O_3
 30 concentration relative to the threshold concentration C_{thres} of 35.1 ppbv , which is obtained from
 31 (Lim et al., 2012) and (Liu et al., 2018). Pop represents the population exposed in the ambient O_3
 32 pollution, which is available from the seventh nationwide population census in 2020 provided by
 33 National Bureau of Statistics of China. The daily y_0 and β values for all non-accidental causes,
 34 hypertension, CVD, RD, COPD, and stroke are summarized in Table S2.

35 3 Unexpected surface O_3 enhancements over the SCB in 2020

36 Figures 1(a)-(b) show the May-June mean MDA8 O_3 concentrations at all measurement sites
 37 over the SCB in 2019 and 2020. The May-June mean MDA8 O_3 concentrations averaged over all

1 cities in the SCB region in 2019 and 2020 are 48.1 ppbv and 58.3 ppbv, which are 11.0 ppbv lower
2 and 1.2 ppbv higher than those averaged over all Chinese cities in the same period, respectively. As
3 the most densely populated and highly industrialized region in western China, the land use,
4 industrialization, infrastructure construction, and urbanization over the SCB have expanded rapidly
5 in recent years, resulting in the highest anthropogenic emissions of O_3 precursors and highest surface
6 O_3 levels in the region (Figure S4). Although the O_3 levels in the SCB cities cluster are lower than
7 those in the three most developed city clusters in eastern China, i.e., the BTH, the Fenwei Plain
8 (FWP), and the YRD city clusters, the SCB region has been classified by the MEE as a newly
9 pollution region for O_3 mitigation (Sun et al., 2021b; Wang et al., 2020a; Wang and Lu, 2019; Zou et
10 al., 2019). Situated in the basin with stationary meteorological fields combined with high
11 anthropogenic emissions, the SCB cities cluster is potential to become a new region with frequent
12 high- O_3 events after BTH, FWP, and YRD.

13 We find significant O_3 enhancements by 10.2 ± 0.8 ppbv (23.4%) (mean $\pm 1\sigma$ standard deviation)
14 averaged over all cities in the SCB in May-June 2020 vs. 2019 levels (Figure 1(c)). The largest
15 enhancements are observed in the most densely populated areas around the megacities Chongqing
16 and Chengdu (11.8 ± 0.6 ppbv (29.9%)). These year-to-year O_3 enhancements over the SCB are
17 record high in the 2015-2020 period, following an increasing change rate of $1.2\% \text{ yr}^{-1}$ from 2015 to
18 2017 and then a decreasing change rate of $-0.7\% \text{ yr}^{-1}$ from 2017 to 2019. These surface O_3
19 enhancements mainly reflect regional emissions and meteorology changes in the SCB and
20 surrounding regions since the lifetimes of surface O_3 and most of its precursors are too short to
21 undergo long range transport.

22 The significant O_3 enhancements over the SCB in May-June 2020 vs. 2019 are opposite to the
23 overall decrease in surface O_3 levels across China in the same period (Figure 1 (d)). After a
24 continuous increase in surface O_3 levels from 2013 to 2019 by approximately $5\% \text{ yr}^{-1}$ (Figure 1(d)),
25 the MDA8 O_3 averaged over all cities outside the SCB across China in May-June 2020 vs. 2019
26 levels showed a significant reduction of 5.3 ± 0.5 ppbv (8.3%). Such O_3 reductions are widespread
27 in the eastern China, especially in the BTH, FWP, and YRD regions, and we have investigated their
28 drivers in a separate study (Yin et al., 2021).

29 **4 Model performance assessment**

30 We use the metrics of normalized root-mean-square error (NRMSE), normalized mean bias
31 (NMB), and Pearson correlation coefficient (R) to assess the performance of the GEOS-Chem-
32 XGBoost model. For each measurement site, we analysed these metrics for both training (blue) and
33 test (red) datasets as shown in Figure S5. We define the NRMSE as the RMSE normalized by the
34 difference between the 95th and 5th percentile concentrations, and NMB as the mean bias
35 normalized by average concentration at the given measurement site. The formulas of above metrics
36 are summarized in Section S2.

37 The GEOS-Chem-XGBoost model predictions for surface O_3 over the SCB show no bias when
38 evaluated against the training data, with NMB of 0.01, NRMSEs of less than 0.1, and R between
39 0.93 – 1.0. Compared to the training data, the performances on the test data show a higher variability,
40 with an average NMB of -0.04 , NRMSE of 0.22, and R of 0.83. We find no significant difference
41 in prediction performance between clean (less than the C_{thres} defined in section 2.5) and polluted
42 measurement sites. A number of factors likely contribute to relatively poorer statistical results at

1 some sites such as Ganzizhou, Leshan, and Suining. First, the training data of these sites may include
2 certain temporal events that are not easily generalizable, such as unusual emissions activity (e.g.,
3 BB, fireworks, closure of nearby point source) or weather patterns that are not properly observed,
4 which might be prone to overfitting. In addition, the differences in surface O₃ variabilities between
5 the training data and the test data at these sites are relative larger than other sites, which can
6 contribute to a relative poorer performance.

7 We use the SHapely Additive exPlanations (SHAP) approach to examine how the GEOS-
8 Chem-XGBoost model uses the input variables to make a prediction. The SHAP approach is based
9 on game-theoretic Shapely values and represents a measure of each predictor's responsibility for a
10 change in the model prediction (Lundberg and Lee, 2017). The SHAP values are computed
11 separately for each model prediction, which offer detailed insight into the importance of each input
12 variable to this prediction while also consider the role of variables interactions (Keller et al.,
13 2021;Lundberg et al., 2020). Figure 2 shows the SHAP value distribution for all the major O₃
14 predictors averaged over all cities in the SCB. The results show that all variables that are expected
15 to be associated with O₃ formation can affect model O₃ prediction. Generally, the temperatures (at
16 the surface, 2 m height, and 10 m height) are the most important predictors for the GEOS-Chem
17 model-to-measurement discrepancy over the SCB, followed by the uncorrected GEOS-Chem
18 simulated O₃, reactive nitrogen (e.g., NO₂, Peroxyacetyl nitrate (PAN)), atmospheric oxidants (O_x,
19 hydrogen peroxide (H₂O₂)), fine aerosols, VOCs (Isoprene, C₃H₈), hour of the day, and
20 meteorological variables including horizontal and vertical wind speeds (u10m, v10m). All of these
21 factors have tight connections to surface O₃ formation over the SCB and it is thus not surprising that
22 the GEOS-Chem model-to-measurement discrepancies are most sensitive to them (Seinfeld and
23 Pandis, 2016).

24 We have compared the performances of GEOS-Chem and GEOS-Chem-XGBoost in capturing
25 the measured surface O₃ levels. Figure 3 (a) shows the time series of measured and model predicted
26 O₃ concentrations averaged over all cities in the SCB region. Figure 3 (b) shows histogram of the
27 differences between the GEOS-Chem-XGBoost predictions and the measurements. The GEOS-
28 Chem simulations generally capture the daily variability of MDA8 O₃ over the SCB, but they show
29 a high bias of 7.8 ± 5.0 ppbv (17.5%) across all measurement sites within the SCB region. The
30 discrepancy can be mainly attributed to uncertainties in the horizontal transport and vertical mixing
31 schemes simulated by the GEOS-Chem model at a relatively coarse spatial resolution compared to
32 the measurements at a single point, and also associated with the errors in emission estimates,
33 chemical mechanism, and the sub-grid-scale local meteorological processes. Especially, errors of
34 O₃ predictors with high SHAP values are more likely to result in large model-to- measurement
35 discrepancy. For example, GEOS-Chem model overestimates the correlations between surface O₃
36 concentration and temperature (Figure S7 (a)), indicating that this overestimation of O₃-to-
37 temperature sensitivity is one of the major factors contributing to higher GEOS-Chem model O₃
38 predictions.

39 By iteratively training and correcting the GEOS-Chem model-to-measurement discrepancy in
40 O₃-to-temperature sensitivity, the correlations between temperature and surface O₃ concentration
41 predicted by the GEOS-Chem-XGBoost model were in good agreement with the measurements
42 (Figure S7 (a)). With respect to the performance of reproducing the sensitivities of O₃ to other
43 meteorological parameters such as humidity, cloud fraction, and precipitation, the GEOS-Chem-
44 XGBoost model is also better than the GEOS-Chem (Figure S7 (b)-(d)). After correcting the errors

1 in all O_3 predictors, the GEOS-Chem-XGBoost model significantly improves the prediction of
2 surface O_3 concentrations in all cities over the SCB compared to the GEOS-Chem (Figure S8). It
3 shows a bias of 0.5 ± 0.3 ppbv for all O_3 measurements in 2019 over the SCB. As a result, the overall
4 GEOS-Chem-XGBoost model performance is acceptable and can support further investigation of
5 the drivers of the unexpected surface O_3 enhancements over the SCB in May-June 2020.

6 **5 Attribution**

7 **5.1 Separation of meteorological and anthropogenic emissions contributions**

8 We quantify the surface O_3 enhancements in May-June 2020 over the SCB to changes in
9 anthropogenic emissions and meteorological conditions according to equations (6) and (7).
10 Differences between the measured and GEOS-Chem-XGBoost predicted O_3 in May-June 2020, as
11 indicated by the shadings in Figure 4(a), represent the anthropogenic emissions-induced O_3 changes
12 in 2020 vs. 2019. Mean contributions driven by changes in anthropogenic emissions and
13 meteorological conditions are summarized in Figure 4(b). Due to the different change rates in
14 anthropogenic emissions in May and June in 2020 (see section 5.3), the changes in anthropogenic
15 emissions caused an overall increase in surface O_3 level in May but a reduction in surface O_3 level
16 in June (Figure 4 (a)). For the May-June mean contributions averaged over all cities in the SCB,
17 changes in anthropogenic emissions caused 0.9 ± 0.1 ppbv of O_3 reduction and changes in
18 meteorology caused 11.1 ± 0.7 ppbv of O_3 increase, which correspond to -8.0% and 108% of
19 relative contributions to the total O_3 enhancement (10.2 ± 0.8 ppbv) over the SCB in May-June 2020,
20 respectively. As a result, the anthropogenic emissions induced O_3 reductions are dominantly
21 overwhelmed by the meteorology induced O_3 increases, leading to the unexpected O_3 enhancements
22 over the SCB in 2020.

23 We compare the meteorology and anthropogenic emissions induced contributions to the
24 unexpected surface O_3 enhancements estimated by the GEOS-Chem-XGBoost model with those by
25 the GEOS-Chem model only (Figure 4 (b)). Both methods show that changes in meteorology
26 contribute significantly to the O_3 enhancements, while the absolute magnitudes differ slightly from
27 each other. For example, the anthropogenic emissions induced O_3 reduction calculated with the
28 GEOS-Chem model only is 0.94 ppbv, while the value for GEOS-Chem-XGBoost model is 1.36
29 ppbv. By taking the subtraction in equation (5) and the average over all cities, the propagation of
30 systematic model discrepancies that are common to all measurements sites was effectively
31 minimized, which can mitigate the difference in attribution results between the GEOS-Chem and
32 GEOS-Chem-XGBoost methods. However, as demonstrated in Figure S8, model discrepancies may
33 differ between regions and time. Therefore, the GEOS-Chem-XGBoost approach is expected to
34 provide a more accurate and consistent estimate on O_3 change attribution than the GEOS-Chem
35 model alone.

36 **5.2 Meteorological contribution**

37 Figure 5 shows the terrain elevations and May-June mean wind fields and surface pressures
38 over the SCB and surrounding regions. The terrain altitudes, at a resolution of 3×3 arc-minute,
39 indicate a rapid change in altitude from the Tibetan Plateau (4.0 – 5.0 km) and Yunan-Kweichou
40 Plateau (2–3 km) to the SCB (0.5 km). The SCB is located in the saddle between the Tibetan and

1 Yunnan-Kweichou Plateau (Chen et al., 2009;Sun et al., 2021c). Figure 5 (b) are the May-June mean
2 wind fields at 500 m overlaid with surface pressure available from GEOS-FP fields at $0.25^{\circ} \times 0.3125^{\circ}$
3 resolution. In May-June, the Tibetan High formed over the middle region of the Tibetan Plateau
4 with the western Pacific Subtropical High shifts westward to the west of the SCB (Chen et al., 2009).
5 The southwesterly East Asian summer monsoon generates a cyclonic pattern over the southeast part
6 of the SCB. Driven by large-scale circulations, southwesterly flow enters the east part of the SCB
7 near the northwest edge of the Yunnan-Kweichou Plateau, while strong northwesterly flow enters
8 the SCB near the east edge of the Tibetan Plateau. The interaction of these two flows results in a
9 convergent zone of northward jet stream over the east part of the SCB due to the westward shift of
10 the Western Pacific Subtropical High and the blocking effect of topography. Furthermore, strong
11 instability of vertical convection could originate over the basin and move toward the east part of the
12 SCB as dry air continuously entered the upper layer over the SCB (Chen et al., 2009). This process
13 makes it a favorable region for trapping air pollutants within the SCB region (Chen et al., 2009;Liu
14 et al., 2003).

15 Figure 6 shows the May-June mean differences in vertical velocity, precipitation, temperature,
16 specific humidity, cloud fraction, and PBLH between 2020 and 2019. In May-June 2020, the
17 northwest, central western and southern China experienced anomalous strong droughts
18 (<https://quotsoft.net/air/>), leading to a significant increase in temperature and decreases in
19 precipitation, specific humidity and cloud fractions compared to the 2019 levels (Figure 6). These
20 changes in meteorological conditions could enhance the natural emissions of O₃ precursors and
21 speed up O₃ chemical production. Meanwhile, the SCB basin effect inhibited the ventilation of O₃
22 and its precursors, which further enhanced the O₃ accumulations over the SCB. As a result, we
23 conclude that the meteorological anomalies combined with the complex basin effect caused the
24 surface O₃ enhancements over the SCB in 2020. Although higher PBLH over the SCB in May-June
25 2020 vs. 2019 may reduce surface O₃ levels by diluting O₃ and its precursors into a larger volume
26 of air, this reduction effect was overwhelmed by the aforementioned enhancement effect. There is
27 no strong evidence for the change in the horizontal transport from other regions (Figure 5(b)) and
28 the vertical transport from the free troposphere to the surface (Figure 6 (a)) over the SCB in May-
29 June 2020 vs. 2019 (Lefohn et al., 2012;Skerlak et al., 2014;Stohl et al., 2003;Wang et al.,
30 2020a;Wang and Lu, 2019;Wang et al., 2020b;Wang et al., 2020c;Wirth and Egger, 1999). It is worth
31 noting that, with similar meteorological anomalies in May-June 2020 vs. 2019, the O₃ enhancements
32 were not observed in the northwest China such as Xinjiang and Inner Mongolia Provinces, and
33 southern China such as the Pearl River Delta (PRD) region, which is also one of the nine well-
34 developed city clusters in China with severe air pollution. This can be partly attributed to low
35 anthropogenic emissions of O₃ precursors in northwest China (Zheng et al., 2018); and that strong
36 exchange between the land and sea in the coastal regions driven by the summer monsoon facilitates
37 the ventilation of O₃ and its precursors in the PRD region. Furthermore, the meteorology induced
38 O₃ enhancements are probably overwhelmed by the anthropogenic emissions induced O₃ reductions
39 in the northwest and southern China.

40 **5.3 Emissions contribution**

41 To suppress the spread of coronavirus pandemic 2019 (COVID-19) across China and above,
42 the Chinese government sealed off several cities starting in January 2020; implementing a few

1 measures such as closing local businesses and halting public transportation at an unprecedented
2 scale (Li et al., 2019b; Steinbrecht et al., 2021; Yin et al., 2021). These prevention measures quickly
3 spread nationwide. Although the COVID-19 lockdowns in all cities have been removed before May,
4 there are still restrictions on public transportation, businesses, social activities and industrial
5 manufactures, which could cause domestic anthropogenic emissions reductions in both HCHO and
6 NO_x. Furthermore, the MEE continues the mitigation of NO_x emissions following the 2018–2020
7 Action Plan on Defending the Blue Sky, and has also implemented The 2020 Action Plan on VOCs
8 Mitigations in 2020. This new Action Plan issues a number of control measures including
9 implementation of stringent VOCs emission standards, replacement of raw and auxiliary materials
10 with low VOCs content, and mitigation of unorganized emissions. Driven by the above factors, the
11 TROPOMI observed tropospheric HCHO and NO₂ over China in May-June 2020 vs. 2019 reduced
12 by $2.0 \pm 0.3\%$ (averaged for all Chinese cities) and $1.1 \pm 0.2\%$, respectively. Due to the relative
13 short lifetime of both HCHO and NO₂ in troposphere, these reductions mostly reflect local emissions
14 changes. These reductions in domestic anthropogenic emissions dominated the significant reduction
15 of summertime MDA8 O₃ across China in 2020 vs 2019.

16 We have used the HCHO/NO₂ ratios following the method of (Sun et al., 2018) to investigate
17 the O₃ production regime over the SCB region. The results show that the satellite observations of
18 HCHO/NO₂ ratios in May-June in most cities over the SCB have indicated a shift toward high values
19 from 2019 to 2020 but the O₃ chemical sensitivity in 2020 still lies within the transitional regime
20 (Jin et al., 2017; Jin and Holloway, 2015; Figure S9). Meanwhile, the O₃ chemical sensitivity in May
21 2020 is similar to that in June, indicating that the O₃ variability in May-June 2020 is sensitive to
22 both NO_x and VOCs. The recently available Chinese anthropogenic emissions statistic data provided
23 by the MEE show that the anthropogenic VOCs over the SCB has decreased by 5.0% and 3.5% in
24 May and June in 2020 relative to the 2019 level, respectively. The anthropogenic NO_x in the same
25 period has increased by 1.5% and decreased by 1.7%, respectively (Zheng et al., 2021). The increase
26 in anthropogenic NO_x in May 2020 vs. 2019 is attributed to an increase in NO_x emission from power
27 plant sector, which was not affected by the post-lockdown restrictions for suppressing the spread of
28 COVID-19 (Table S3). For the May-June aggregation, the anthropogenic VOCs and NO_x over the
29 SCB have decreased by 4.3% and 0.3%, respectively (Zheng et al., 2021). These independent
30 analyses on anthropogenic emissions explain the different predicted O₃ changes due to
31 anthropogenic emissions alone in May (increase) versus June (decrease) in the SCB.

32 In contrast to the widespread reductions in both HCHO and NO₂ across the BTH, FWP, and
33 YRD regions, we find notable increases in both HCHO and NO₂ in the SCB in May-June 2020 vs.
34 2019 levels. The tropospheric HCHO and NO₂ columns averaged over all cities in the SCB region
35 have been increased by $(2.8 \pm 0.3\%)$ and $(5.1 \pm 0.5\%)$ in 2020 vs. 2019 levels, respectively. Since
36 both anthropogenic VOCs and NO_x emissions in the SCB showed decreasing change rates in May-
37 June 2020 vs. 2019, these regional increases in both HCHO and NO₂ could thus be attributed to
38 natural emissions enhancements in both VOCs and NO₂ in the SCB. Indeed, natural emissions of
39 biogenic VOCs and soil NO_x calculated online in the GEOS-Chem model show increasing change
40 rates in May-June 2020 vs. 2019 in the SCB and surrounding regions (Figure 7). These enhanced
41 biogenic VOCs and NO_x emissions are most likely driven by the hotter and dryer meteorological
42 conditions in the SCB and surrounding regions (Figure 7).

43 Finally, we concluded that natural emissions enhancements of both NO_x and VOCs induced by
44 the unexpected meteorological anomalies could be accounted for the O₃ enhancements in May-June

1 2020 over the SCB, and their contributions have been included in the meteorology-driven ozone
2 enhancement as discussed in Section 5.2. In present work, we were not able to determine which
3 specific VOCs species are the most effective for O_3 enhancements and cannot quantify the relative
4 contributions of VOCs and NO_x enhancements to the O_3 enhancements in the SCB. A series of
5 sensitivity studies might be able to address this important issue, but this is beyond the scope of
6 present work.

7 **6 Health risks for the O_3 enhancements over the SCB**

8 Figure 8 presents the total premature mortalities from all non-accidental causes, hypertension,
9 CVD, RD, COPD, and stroke attributable to ambient O_3 exposure in all cities over the SCB during
10 May-June in 2019 and 2020. The statistical results for each city in 2019 and 2020 are summarized
11 in Tables S4 and S5, respectively. The surface O_3 enhancements over the SCB in May-June 2020
12 vs. 2019 results in dramatically higher health risks. The estimated total premature mortalities from
13 all non-accidental causes due to the surface O_3 enhancements in May-June 2020 over the SCB is
14 5455, which is 89.8% higher than that in the same period in 2019 (i.e., 2874). All above O_3 induced
15 diseases over the SCB have significant increases in total mortalities in May-June 2020 vs. 2019.
16 The highest health risk among these diseases is from CVD which is 741 in May-June 2019, followed
17 by RD (236), COPD (231), and hypertension (223). This O_3 induced health risk rank over the SCB
18 is consistent with those in the YRD, BTH, and PRD in previous studies (Liu et al., 2018; Lu et al.,
19 2020; Yin et al., 2017; Wang et al., 2021). In May-June 2020, total mortalities from CVD, RD,
20 COPD, hypertension, and stroke over the SCB reached to 1405, 450, 439, 418, and 46, respectively,
21 due to significant O_3 enhancements. The change rates for these diseases are 89.6, 90.7, 90.1, 87.4,
22 and 91.7%, respectively.

23 From a whole year view, the estimated total premature mortalities from all non-accidental causes
24 due to surface O_3 exposure over the SCB in 2019 and 2020 are 16,772 and 18,301,
25 respectively (Tables S4 and S5). All O_3 induced diseases within May-June 2019 account for about
26 ~17.0% of those in the whole year 2019, and this percentage reaches up to ~30.0% in 2020 (Figure
27 S10). The total premature mortalities from all non-accidental causes due to surface O_3 exposure
28 over the SCB has increased by 1528 in the whole year 2020 vs. 2019 (Figure S11), which is 40.8%
29 lower than that within May-June 2020 vs. 2019 (i.e., 2581). This indicates that the O_3 level over the
30 SCB showed an overall decreasing change rate in all months except May-June in 2020 vs. 2019,
31 which resulted in a decrease (by 1053) in O_3 induced diseases in the period.

32 We further investigated the O_3 induced diseases in the two most densely populated cities over
33 the SCB (i.e., Chengdu and Chongqing) during May-June in 2019 and 2020. The premature
34 mortalities from all O_3 induced diseases in 2020 vs. 2019 in each city are dependent on regional
35 population, surface O_3 level, and enhancement level (equation (9)). With the largest populations and
36 highest O_3 enhancements, the estimated total premature mortalities in Chengdu and Chongqing
37 accounted for 46.9% of total O_3 induced mortalities over the SCB during May-June 2020 (Figure 8
38 (b)-(c)). Since the O_3 levels and enhancement in Chengdu are larger than those in Chongqing, the
39 total O_3 induced mortalities in Chengdu are larger even with smaller population. The change rates
40 for all O_3 induced diseases are about 75% in Chengdu and 160% in Chongqing during May-June
41 2020 vs. 2019, which are much higher than the enhancement of ozone levels in the two cities
42 (29.9 %). In order to reduce the O_3 induced health risk, strident O_3 control policies are necessary in

1 densely populated cities.

2 **7 Conclusions**

3 Understanding the drivers and health risks of surface high O₃ events has a strong implication
4 for O₃ mitigation purpose. After a continuous increase in surface O₃ level from 2013 to 2019, the
5 overall summertime O₃ concentration across China showed a significant reduction in 2020. In
6 contrast to this overall reduction in surface O₃ level across China, unexpected surface O₃
7 enhancements of 10.2 ± 0.8 ppbv (23%) were observed in May-June 2020 vs. 2019 over the Sichuan
8 basin (SCB), China. In this study, we have used high resolution nested-grid GEOS-Chem simulation,
9 the eXtreme Gradient Boosting (XGBoost) machine learning method and the exposure-response
10 relationship to determine the drivers and evaluated the health risks of the unexpected surface O₃
11 enhancements.

12 By iteratively training and correcting the GEOS-Chem model-to-measurement discrepancies,
13 the GEOS-Chem-XGBoost model significantly improves the prediction of surface O₃
14 concentrations compared to the GEOS-Chem. It shows a bias of 0.5 ± 0.3 ppbv against all O₃
15 measurements over the SCB. As a result, the overall GEOS-Chem-XGBoost model performance is
16 acceptable and can support further investigation of the drivers of the unexpected surface O₃
17 enhancements over the SCB in May-June 2020. The results show that changes in anthropogenic
18 emissions caused 0.9 ± 0.1 ppbv of O₃ reduction and changes in meteorology caused 11.1 ± 0.7
19 ppbv of O₃ increase. The meteorology-induced surface O₃ increase is mainly attributed to an
20 increase in temperature and the decreases in precipitation, specific humidity and cloud fractions
21 over the SCB and surrounding regions in 2020 vs. 2019 levels. These changes in meteorology
22 combined with the complex SCB basin effect enhanced biogenic emissions of VOCs and NO_x,
23 speeded up O₃ chemical production, and inhabited the ventilation of O₃ and its precursors, and
24 therefore caused the surface O₃ enhancements over the SCB.

25 The unexpected surface O₃ enhancements over the SCB in May-June 2020 vs. 2019 result in
26 dramatically higher health risks. The estimated total premature mortalities due to the unexpected
27 surface O₃ enhancements over the SCB during May-June 2020 is 5455, which is 89.8% higher than
28 that in the same period in 2019 (i.e., 2874). We further investigated the O₃ induced diseases in the
29 two most densely populated cities over the SCB (i.e., Chengdu and Chongqing) during May-June
30 in 2019 and 2020. With largest populations and highest O₃ enhancements, the estimated total
31 premature mortalities in Chengdu and Chongqing accounted for 46.9% of total O₃ induced
32 mortalities over the SCB. The change rates for all O₃ induced diseases are about 75% in Chengdu
33 and 160% in Chongqing during May-June 2020 vs. 2019, which are much higher than the
34 enhancement of ozone levels in the two cities (29.9 %). In order to reduce the O₃ induced health
35 risks, strident O₃ control policies are necessary in densely populated cities.

36 **Code and data availability.** Surface O₃ measurements over the SCB are from
37 <http://www.cnemc.cn/en/>. All other data are available on request of YS (ywsun@aiofm.ac.cn)

38 **Author contributions.** YS designed the study and wrote the paper. HY carried out the GEOS-Chem
39 simulations and GEOS-Chem-XGBoost training and evaluation. XL designed the concept of health
40 risk evaluation and revised the manuscript. BZ constructed the latest MEIC emission inventory. JN,

1 MP, CL, and YT provided constructive comments.

2 **Competing interests.** None.

1 **Tables**

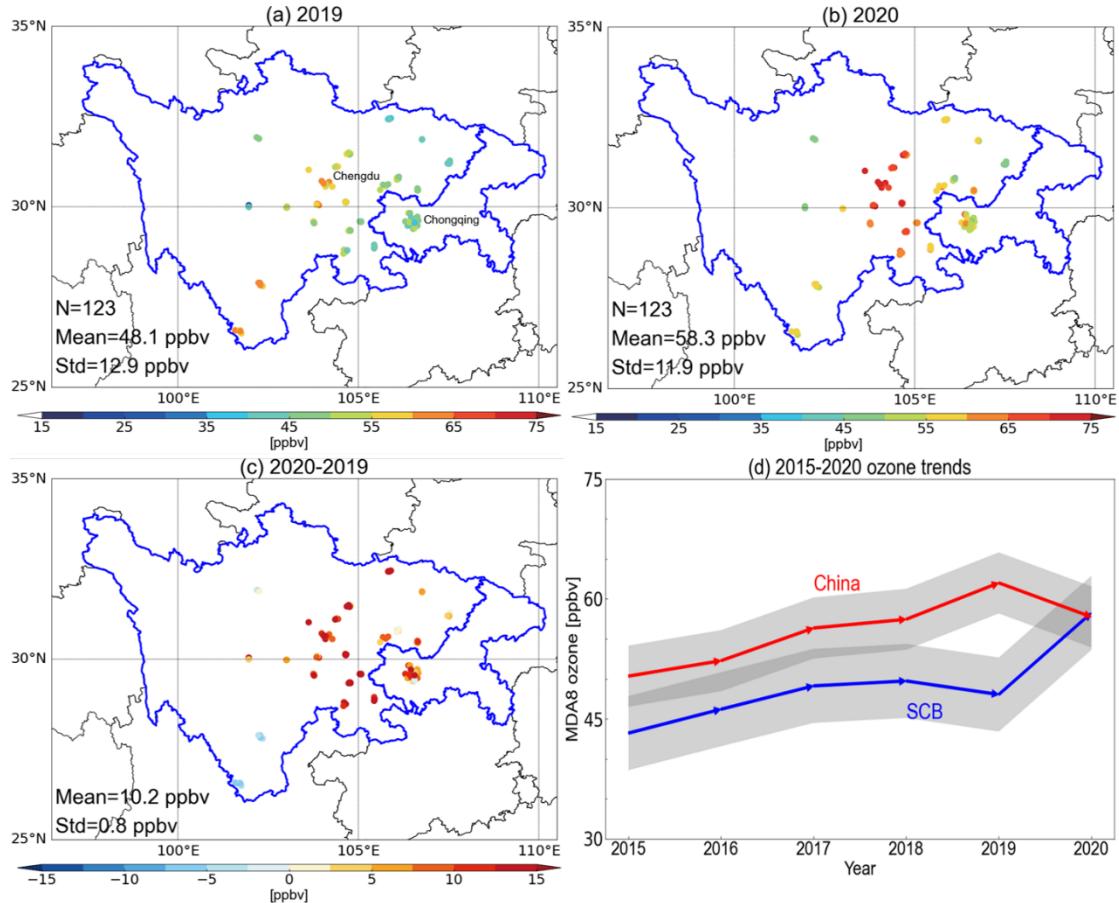

2 **Table 1.** Measurement sites in the SCB city clusters. All sites are organised alphabetically. Population statistics are
 3 based on the seventh nationwide population census in 2020 provided by National Bureau of Statistics of China.

Name	Longitude mean	Latitude mean	Altitude mean (km)	Population	Number of sites	Time period
Abazhou	102.21°E	31.91°N	3.5	822,587	3	2015 - present
Bazhong	106.75°E	31.85°N	0.8	2,712,894	4	2015 - present
Chengdu	104.04°E	30.69°N	0.5	20,938,000	10	2015 - present
Chongqing	106.51°E	29.58°N	0.4	32,054,200	21	2015 - present
Dazhou	107.5°E	31.22°N	1.0	5,385,422	5	2015 - present
Deyang	104.39°E	31.12°N	0.5	3,456,161	4	2015 - present
Ganzizhou	101.96°E	30.05°N	3.5	1,107,431	2	2015 - present
Guangan	106.63°E	30.48°N	1.7	3,254,883	6	2015 - present
Guangyuan	105.85°E	32.44°N	2.1	2,305,657	4	2015 - present
Leshan	103.76°E	29.57°N	0.5	3,160,168	4	2015 - present
Liangshanzhou	102.28°E	27.87°N	2.3	4,858,359	5	2015 - present
Luzhou	105.43°E	28.9°N	0.3	4,254,149	4	2015 - present
Meishan	103.85°E	30.07°N	0.8	2,955,219	6	2015 - present
Mianyang	104.73°E	31.48°N	0.7	4,868,243	4	2015 - present
Nanchong	106.09°E	30.8°N	0.3	5,607,565	6	2015 - present
Neijiang	105.05°E	29.59°N	0.5	3,140,678	4	2015 - present
Panzhihua	101.69°E	26.56°N	2.6	1,212,203	5	2015 - present
Suining	105.71°E	30.58°N	0.5	2,814,196	4	2015 - present
Yaan	103.01°E	29.99°N	3.1	1,434,603	4	2015 - present
Yibin	104.62°E	28.78°N	2.0	4,588,804	6	2015 - present
Zigong	104.75°E	29.35°N	0.3	2,489,256	6	2015 - present

1 **Figures**

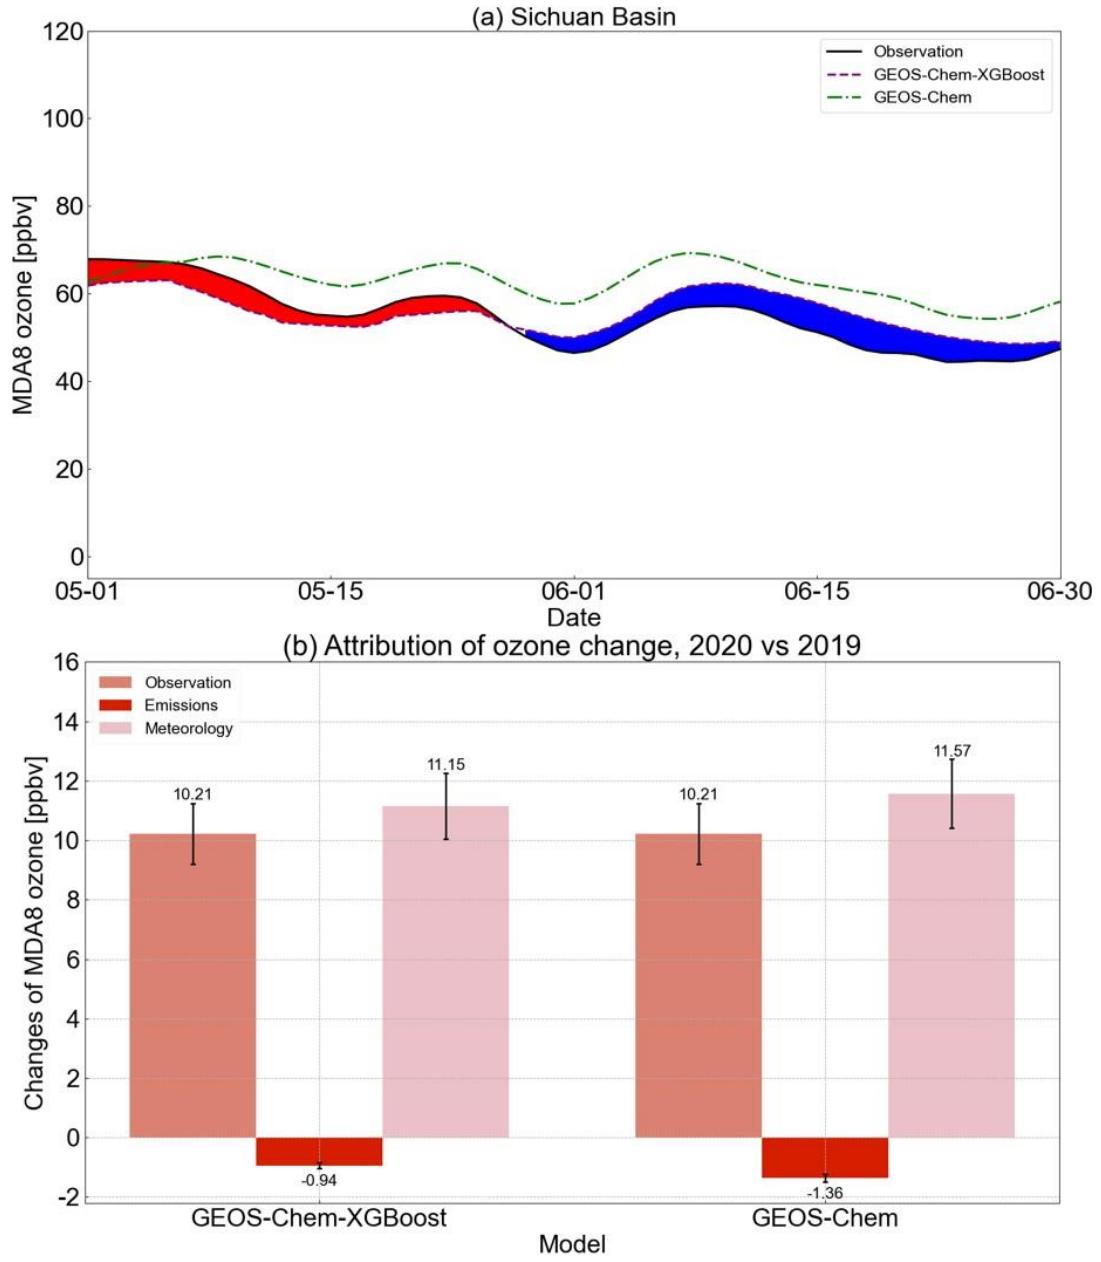

2
3 **Figure 1** Surface O₃ enhancements over the SCB region in May-June 2020 vs. 2019. (a) Spatial distributions of
4 May-June mean O₃ concentrations over the SCB region in 2019. Number (N) denotes available measurement sites
5 for this year. We average the O₃ concentrations at all measurement sites in each city to form a city representative O₃
6 dataset. (b) Same as (a) but for 2020. (c) Differences between 2020 and 2019. (d) Trends in May-June mean ozone
7 concentrations from 2015-2020 averaged for all Chinese cities (red) and for the SCB cities cluster (blue). Grey
8 shadings represent the range of mean value $\pm 1\sigma$ STD across all cities. The base map of the figure is created by the
9 Basemap package of Python.

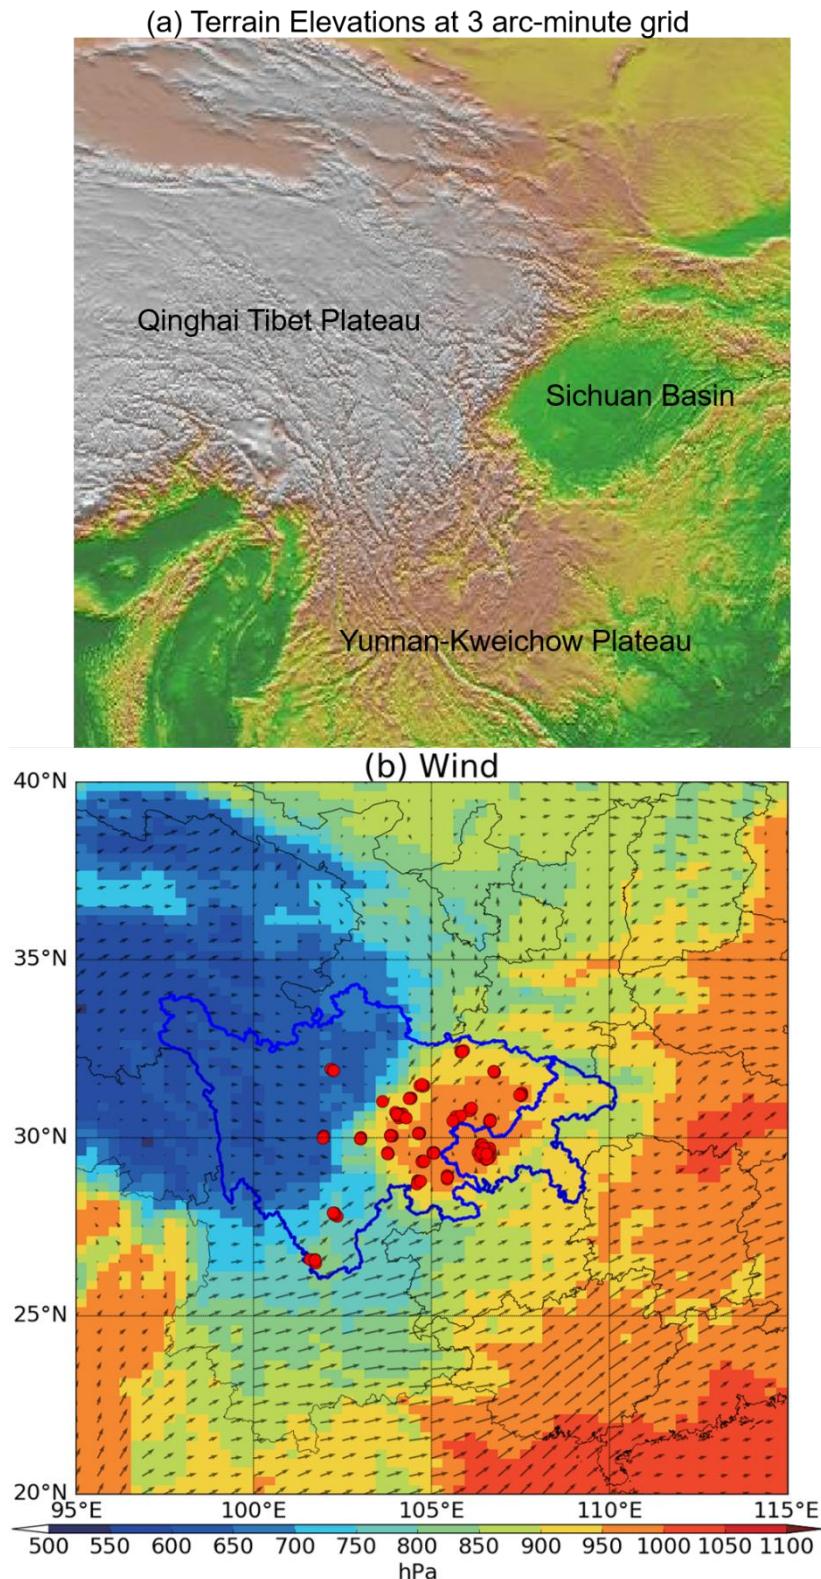

1
2 **Figure 2** Importance of input variables for the XGBoost model trained to correct the GEOS-Chem model-to-
3 measurement O₃ discrepancy over the SCB. Shown are the distribution of the SHAP values for each variable
4 averaged over all cities in the SCB, ranked by the average importance of each feature. Higher SHAP value indicates
5 higher feature importance. Descriptions for all acronyms are listed in Table S1. For clarity, only the top 30 variables
6 are shown. See Figure S6 for importance of all variables.

1 **Figure 3** Measured and modelled O_3 variabilities over the SCB in 2019 (a). Measured, GEOS-Chem, and GEOS-
2 Chem-XGBoost predicted O_3 values are denoted by black solid, grey dashed, and purple dashed lines, respectively.
3 (b) Histogram of the differences between the GEOS-Chem-XGBoost predictions and the measurements.
4

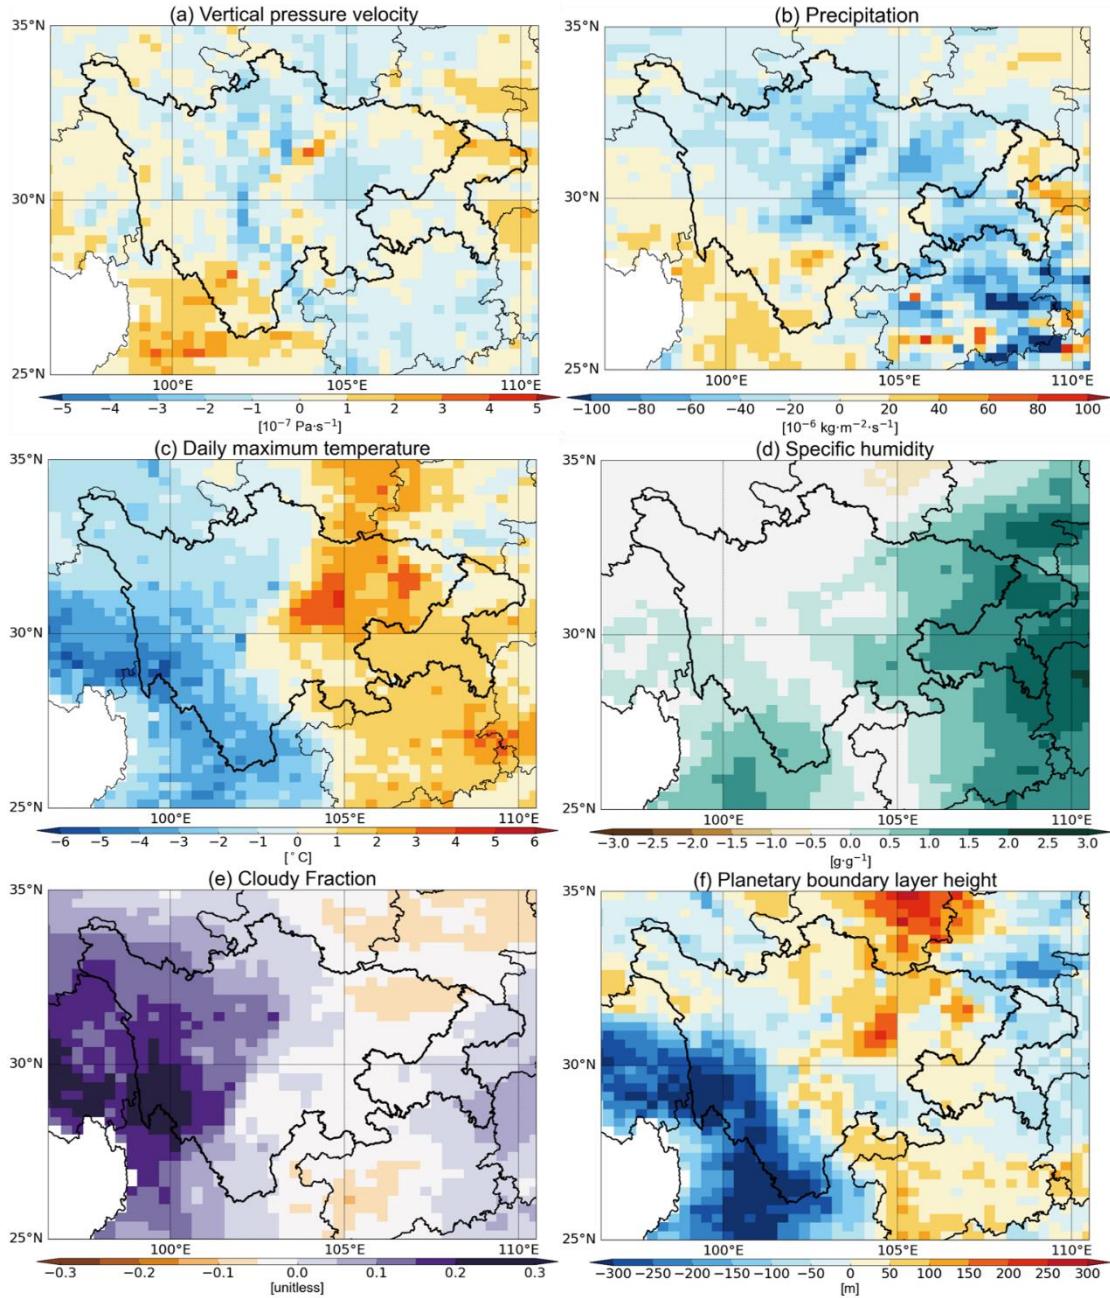

1 **Figure 4** (a) Comparison of the GEOS-Chem-XGBoost O_3 predictions to the 2020 measurements. Red (blue)
2 shadings represent where GEOS-Chem-XGBoost predictions are higher (lower) than the actual measurements in
3 2020, indicating that changes in anthropogenic emission lead to O_3 increase (decrease) in 2020. All values shown
4 are 7-day average for presentation purpose. (b) Attribution of surface O_3 enhancements over the SCB in May-June
5 2020 vs. 2019. Filled colored bars denote O_3 change as seen from measurements, and due to changes in
6 anthropogenic emission and meteorological conditions estimated by the GEOS-Chem-XGBoost model and the
7 GEOS-Chem model. Black vertical bars represent 1σ STD across cities.
8

1

2 **Figure 5** Terrain elevations (a) and surface temperature and wind fields (b) over the SCB and surrounding regions.
 3 The spatial resolutions for (a) and (b) are 3×3 arc-minute and $0.25^\circ \times 0.25^\circ$, respectively. The white area in black
 4 line is Tibetan Plateau (with altitudes of 4–5 km a.s.l.), the yellow area in red line is the Yunnan-Kweichou Plateau
 5 (2–3 km a.s.l.), the green area in circle is the SCB (0.5–1 km a.s.l.). The base map of the figure is created by the
 6 Basemap package of Python.

1

2 **Figure 6** May-June mean differences in vertical pressure velocity (a), precipitation (b), temperature (c), specific
3 humidity (d), cloud fraction (e), and PBLH (f) between 2020 and 2019 over the SCB and surrounding regions. All
4 these meteorological parameters are from the GEOS-FP dataset. The vertical pressure velocity is prescribed at the
5 PBLH and others are at the surface. The base map of the figure is created by the Basemap package of Python.

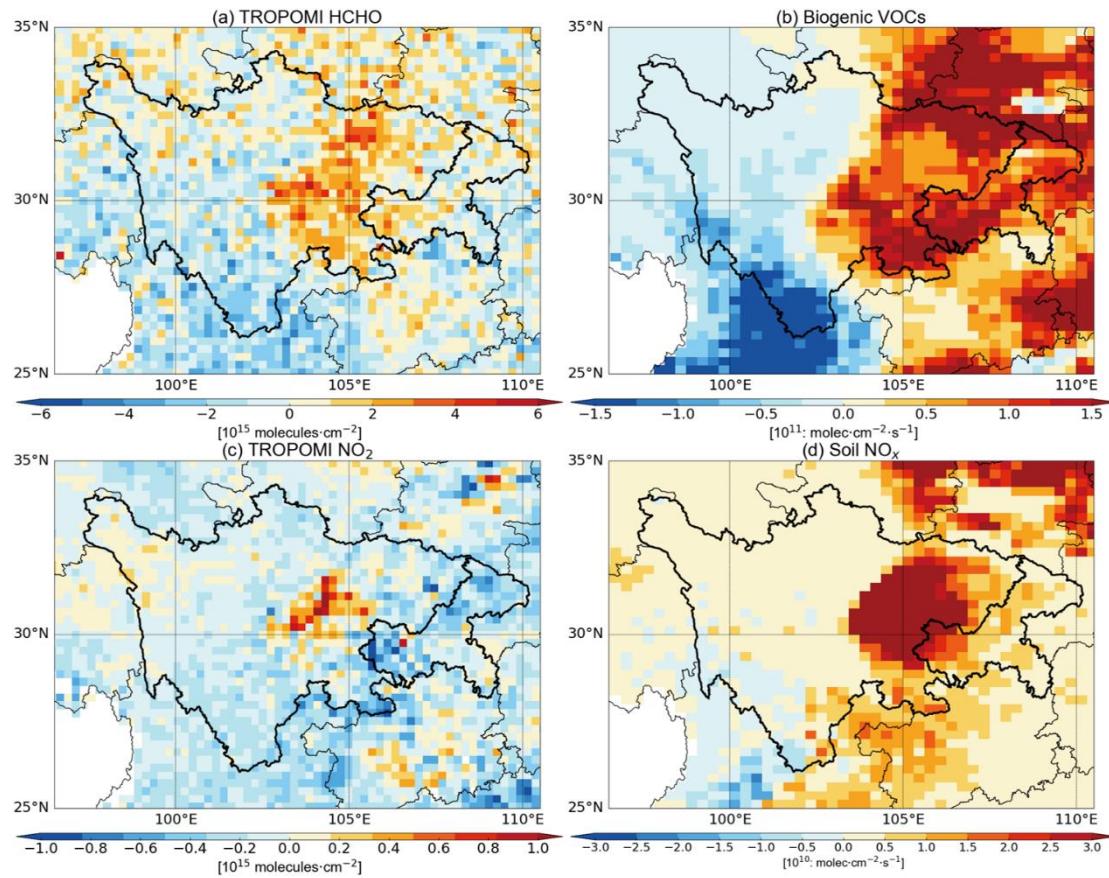

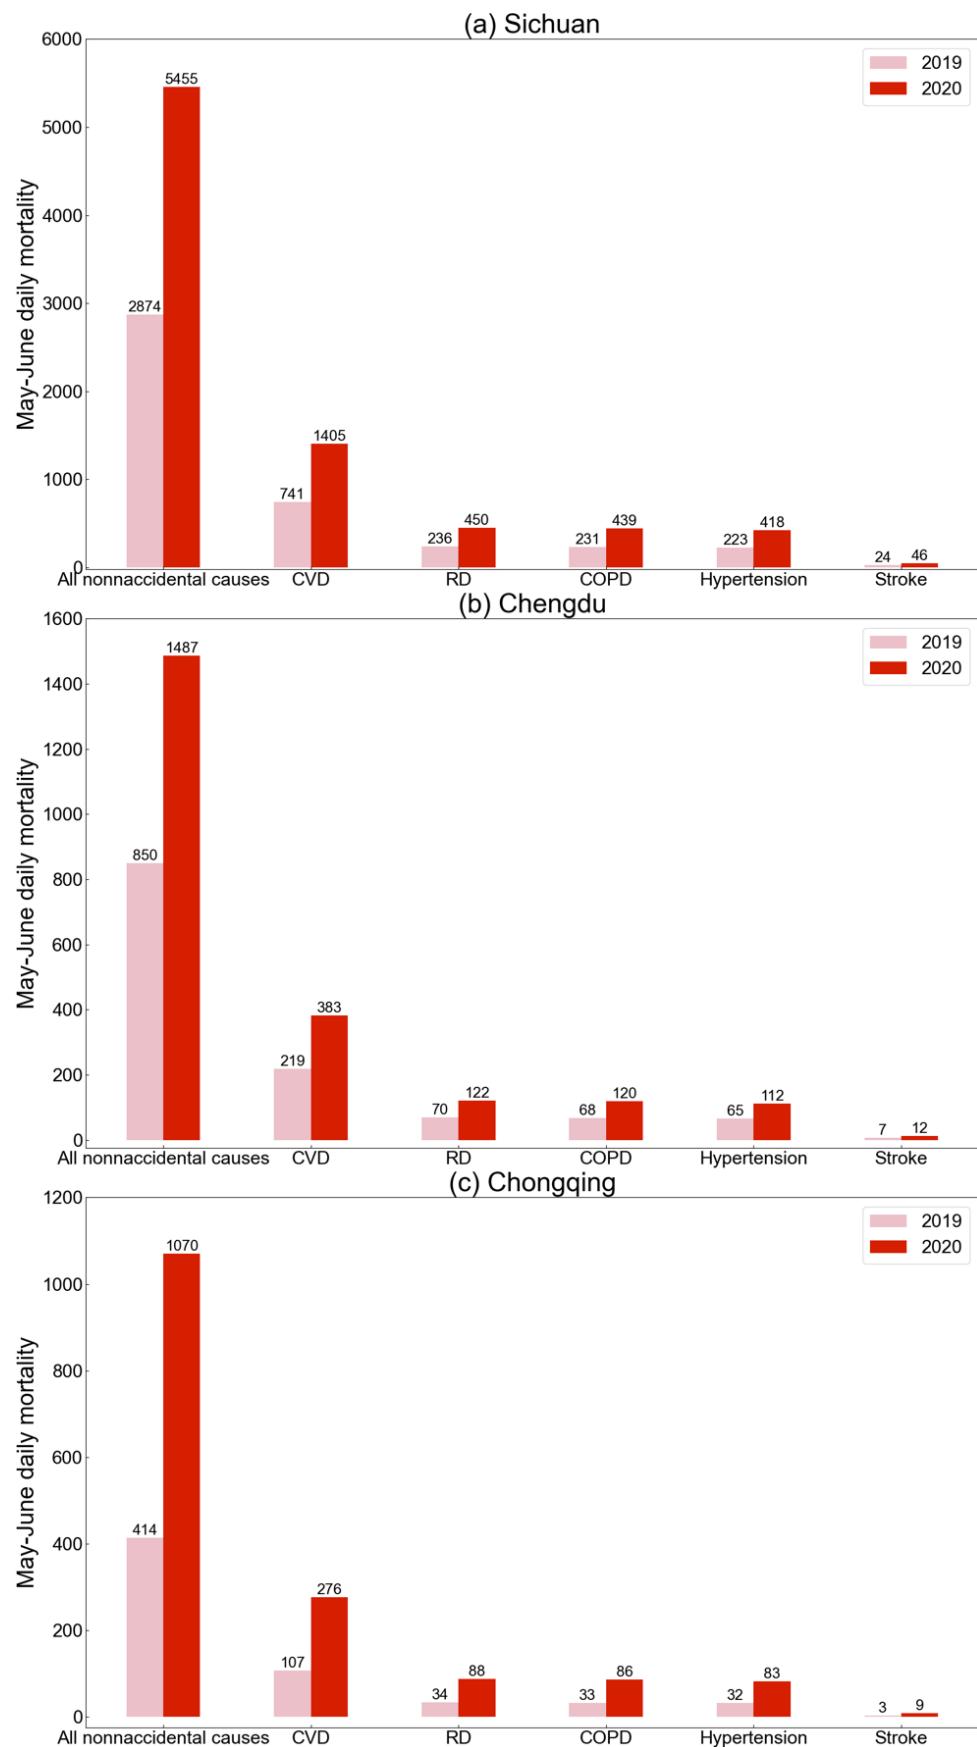

Figure 7 May-June mean differences in O₃ precursors between 2020 and 2019. (a) TROPOMI observed HCHO, (b) biogenic VOCs, (c) TROPOMI observed NO₂, and (d) Soil NO_x. Biogenic VOCs and soil NO_x are available from GEOS-Chem model online calculations. The base map of the figure is created by the Basemap package of Python.

1 **Figure 8** Total daily mortality from all non-accidental causes, CVD, RD, COPD, hypertension, and stroke
2 attributable to ambient O₃ exposure over the SCB during May-June in 2019 and 2020.
3
