18 **Abstract**

19 Aerosols can enhance ecosystem productivity by increasing diffuse radiation. Such  
20 diffuse fertilization effects (DFEs) vary among different aerosol compositions and sky  
21 conditions. Here, we apply a suite of chemical, radiation, and vegetation models in  
22 combination with ground- and satellite-based measurements to assess the impacts of  
23 natural and anthropogenic aerosol species on gross primary productivity (GPP) through  
24 DFE during 2001-2014. Globally, aerosols increase GPP by 8.9 Pg C yr<sup>-1</sup> at clear skies  
25 but only 0.95 Pg C yr<sup>-1</sup> at all skies. Anthropogenic aerosols account for 41% of the total  
26 GPP enhancement though they contribute only 25% to the increment of diffuse  
27 radiation. Sulfate/nitrate aerosols from anthropogenic sources make dominant  
28 contributions of 33% (36%) to aerosol DFE at all (clear) skies, followed by the ratio of  
29 18% (22%) by organic carbon aerosols from natural sources. In contrast to other species,  
30 black carbon aerosols decrease global GPP by 0.28 (0.12) Pg C yr<sup>-1</sup> at all (clear) skies.  
31 Long-term simulations show that aerosol DFE is increasing 2.9% yr<sup>-1</sup> at all skies mainly  
32 because of a downward trend in cloud amount. This study suggests that the impacts of  
33 aerosols and cloud should be considered in projecting future changes of ecosystem  
34 productivity under varied emission scenarios.

37 aerosols, natural aerosols, YIBs model

38

## 39 **1 Introduction**

40 Diffuse light enhances plant photosynthesis more efficiently than direct light (Gu et  
41 al., 2002;Alton et al., 2007;Mercado et al., 2009;Jing et al., 2010;Cirino et al.,  
42 2014;Zhou et al., 2021b;Zhou et al., 2021c). The cause for such difference is that diffuse  
43 light can penetrate into the deep canopy and enhance light use efficiency  
44 ( $LUE=GPP/PAR$ , gross primary production per photosynthetically active radiation) of  
45 shaded leaves (Roderick et al., 2001;Gu et al., 2003;Rap et al., 2015). However, direct  
46 light is absorbed only by sunlit leaves and much of it is wasted because these leaves are  
47 usually at the light saturated conditions (Gu et al., 2002;He et al., 2013). As a result,  
48 increasing the diffuse radiation can help promote canopy photosynthesis through the  
49 diffuse fertilization effect (DFE).

50 Atmospheric aerosols can alter the quality of sunlight reaching Earth's surface by  
51 absorbing and scattering solar insolation (Zhou et al., 2021a). The aerosol-induced  
52 radiative impacts on terrestrial ecosystem productivity have been investigated in both  
53 observational and modeling studies (Table 1). Observations found unexpected decline  
54 of atmospheric carbon dioxide in 1990s, which was attributed to the increase of  
55 vegetation carbon uptake owing to the massive eruption of Mt. Pinatubo in 1991  
56 (Roderick et al., 2001). Sulfate aerosols from volcanic eruption almost doubled diffuse  
57 radiation at the clear sky, leading to the enhancement of plant productivity by 23% at  
58 Harvard forests in 1992 (Gu et al., 2003). With the development of ground-based  
59 instruments and satellite remote sensing, more observational data have been applied to  
60 detect the aerosol DFE. Strada et al. (2015) estimated aerosol DFE on plant productivity

61 using aerosol optical depth (AOD) from satellite cloudless observations at 10 flux sites,  
62 and found that aerosols enhance GPP by 13% in midday hours under high AOD  
63 conditions ( $>0.4$ ) for deciduous and mixed forests. Similarly, Ezhova et al. (2018) found  
64 that aerosols increase clear-day diffuse fraction from 0.11 to 0.27 at five remote sites in  
65 Eurasia, leading to the enhancement of site-level GPP by 6-14%.

66 In contrast to the large benefits at clear days, the aerosol DFE is limited at cloudy  
67 days. Kanniah et al. (2013) explored cloud direct radiative effects on canopy  
68 productivity using observed carbon fluxes and radiation in tropical savannas, and found  
69 that thick cloud masked aerosol DFE and reduced GPP by 26%. Cirino et al. (2014)  
70 also found that aerosol DFE cannot increase plant photosynthesis under cloudy  
71 conditions. These studies indicated that aerosol DFE is subject to sky conditions and  
72 aerosol loading, because the potential benefits from DFE can be offset or even reversed  
73 by simultaneous reductions in direct radiation caused by thick cloud or high aerosol  
74 loading (Alton, 2008; Cirino et al., 2014; Yue and Unger, 2017; Zhou et al., 2021a).

75 Although observational studies directly estimate site-level aerosol DFE, they are not  
76 able to reveal regional or global aerosol DFE due to the limited spatiotemporal coverage.  
77 On the global scale, studies using varied models showed that aerosol DFE enhances  
78 global GPP by  $4.9 \text{ Pg C yr}^{-1}$  (Chen and Zhuang, 2014), 1-2% (Strada and Unger, 2016)  
79 and  $1.0 \pm 0.2 \text{ Pg C yr}^{-1}$  (Yue and Unger, 2018) at different periods. Rap et al. (2018)  
80 specifically explored DFE from biogenic aerosols and found that biogenic aerosols  
81 enhance global NPP by  $1.23 \text{ Pg C yr}^{-1}$ . Regionally, Matsui et al. (2008) applied a land  
82 surface model and estimated that aerosol DFE decreased net primary production (NPP)

83 by 0.09% in 2000 but increased NPP by 0.5% in 2001 over eastern U.S., because the  
84 cloud optical depth was about half in 2001 relative to 2000. At the same region, Keppel-  
85 Aleks and Washenfelder (2016) estimated sulfate aerosol DFE using Community Earth  
86 System Model and found that the reductions of sulfate aerosols by  $3.0 \pm 0.6\% \text{ yr}^{-1}$  led to  
87 reductions of  $0.6\% \text{ yr}^{-1}$  in diffuse radiation and  $0.07\% \text{ yr}^{-1}$  in regional GPP during 1995-  
88 2013. In Amazon, fire aerosols are estimated to play varied DFEs among different  
89 studies (Rap et al., 2015; Moreira et al., 2017; Yue and Unger, 2018; Malavelle et al.,  
90 2019). For example, Rap et al. (2015) found that fire aerosols enhance NPP by 1.4-2.8%  
91 while Moreira et al. (2017) estimated that fire aerosols enhance GPP by 27%. Such  
92 differences are mainly attributed to the high aerosol loading in Moreira et al. (2017) for  
93 September 2010, but much lower loading in Rap et al. (2015) for the 10-year (1998-  
94 2007) averages. Although these studies assessed the DFE of total aerosols or the  
95 specific species (e.g., sulfate, fire, or biogenic), the individual DFEs of natural and  
96 anthropogenic aerosols on global terrestrial productivity remain unclear.

97 In this study, we explore the impacts of natural and anthropogenic aerosol DFE on  
98 global GPP during 2001-2014 using both multi-source observations and a series of well-  
99 validated models. A chemical transport model (CTM) is used to predict changes of  
100 natural and anthropogenic aerosol concentrations. A radiative transfer model is applied  
101 to calculate the perturbations in direct and diffuse PAR caused by aerosols. A global  
102 dynamic vegetation model is used to quantify changes of global GPP caused by aerosol  
103 DFE. The main objectives are (1) to distinguish the DFEs of natural and anthropogenic  
104 aerosols on global GPP and (2) to explore the different characteristics of aerosol DFEs

105 for varied species.

106

## 107 **2 Methods**

### 108 **2.1 Chemical transport model**

109 The Goddard Earth Observing System coupled with Chemistry (GEOS-Chem,  
110 <http://geos-chem.org>) is a three-dimensional (3-D) CTM for simulating atmospheric  
111 compositions and air quality (Bey et al., 2001). Global anthropogenic emissions during  
112 2001-2014 are from the Community Emissions Data System (CEDS) inventory  
113 (<http://www.globalchange.umd.edu/ceds/>). The CEDS inventory has been used as  
114 anthropogenic emissions in the Coupled Model Intercomparison Project Phase 6  
115 (CMIP6), and this emission database relies on existing energy consumption datasets  
116 and regional or country-specific inventories to produce trends over recent decades  
117 (Hoesly et al., 2018). The specific emission species include aerosols (black carbon,  
118 organic carbon), aerosol precursors and reactive compounds (SO<sub>2</sub>, NO<sub>x</sub>, NH<sub>3</sub>, CH<sub>4</sub>, CO,  
119 and non-methane volatile organic compounds (VOCs)) (Supplementary Table 1). To  
120 estimate modeling uncertainties due to emission inventories, the Emissions Database  
121 for Global Atmospheric Research (EDGAR) inventory vision 4.3.1  
122 (<https://edgar.jrc.ec.europa.eu/>) during 2001-2010 is also used as alternative  
123 anthropogenic emissions for GEOS-Chem model. For natural emissions, the Global  
124 Fire Emission Database (GFED) version 4 inventory is used to represent emissions  
125 from open fires (<http://www.globalfiredata.org/>). Biogenic VOC emissions are  
126 calculated using the Model of Emissions of Gases and Aerosols from Nature (MEGAN

127 v2.1) (Guenther et al., 2012). Natural emissions of sea salt (Jaeglé et al., 2011), dimethyl  
128 sulfate (Breider et al., 2017), volcanic SO<sub>2</sub> (Fisher et al., 2011) and NH<sub>3</sub> are from the  
129 Global Emissions Initiative (GEIA, <http://www.geiacenter.org/>). In this study, GEOS-  
130 Chem version 12.0.0 is used to simulate concentrations of natural and anthropogenic  
131 aerosols at a horizontal resolution of 4°×5° and 47 vertical layers. The CTM is driven  
132 with assimilated meteorology from the Modern-Era Retrospective analysis for  
133 Research and Applications, version 2 (MERRA2).

134

## 135 **2.2 Radiative transfer model**

136 The Column Radiation Model (CRM) is the standalone version of the radiative  
137 transfer module used by the NCAR Community Climate Model  
138 (<http://www.cesm.ucar.edu/models/>). In this model, aerosol direct radiative effects  
139 including absorbing and scattering processes are calculated at 20 vertical layers from  
140 surface to 0.5 hPa at hourly intervals (Yue and Unger, 2017). The CRM utilizes aerosol  
141 profiles of all species simulated by GEOS-Chem, including sulfate, nitrate, black  
142 carbon (BC), organic carbon (OC), dust (clay and silt) and sea salt (coarse and  
143 accumulation modes). Aerosol optical parameters (e.g. single scattering albedo,  
144 extinction coefficients, and asymmetric parameters) are adopted from Yue and Liao  
145 (2012) for sea salt, Yue et al. (2010) for mineral dust, and the RegCM4 model for other  
146 species (Giorgi et al., 2012). In this study, the CRM is used to simulate aerosol-induced  
147 perturbations in surface radiative fluxes including diffuse and direct PAR. The model  
148 is driven with hourly 1°×1° meteorology from MERRA-2 reanalyses, and 3-hourly

149 cloud cover and liquid water path from CERES SYN1deg (<http://ceres.larc.nasa.gov>).

150

### 151 **2.3 Dynamic vegetation model**

152 The Yale Interactive terrestrial Biosphere (YIBs) model is a process-based vegetation  
153 model that dynamically simulates tree growth and leaf area changes (Yue and Unger,  
154 2015). The model uses the well-established leaf photosynthesis (Farquhar et al., 1980)  
155 and stomatal conductance schemes (Ball et al., 1987). The canopy is divided into sunlit  
156 and shaded portions to separate photosynthetic responses to diffuse and direct light  
157 (Spitters et al., 1986). We distinguish light absorption between sunlit (receiving both  
158 diffuse and direct light) and shaded leaves (receiving only diffuse light), and derive  
159 canopy photosynthesis as the sum of that from sunlit and shaded leaves:

$$160 \quad A_{total} = A_{sunlit} \times F_{sunlit} + A_{shaded} \times (1 - F_{sunlit}) \quad (1)$$

161 where  $A_{sunlit}$  and  $A_{shaded}$  are the photosynthesis of sunlit and shaded leaves,  
162 respectively. The fraction of sunlit leaf area  $F_{sunlit}$  is calculated as:

$$163 \quad F_{sunlit} = e^{-kL} \quad (2)$$

164 Here,  $L$  is leaf area index (LAI) at one canopy layer and  $k$  is extinction coefficient  
165 defined as  $0.5/\cos\alpha$  (solar zenith  $\alpha$ ).

166 Simulated GPP by YIBs model were validated using ground-based observations at  
167 145 sites and yielded an average correlation coefficient of 0.76 for all sites (Yue and  
168 Unger, 2015). The simulated global GPP also shows reasonable spatiotemporal  
169 variations compared with satellite retrievals (Yue et al., 2015). Recently, the model  
170 joined the multi-model ensemble project of TRENDY to provide the estimates of global

171 carbon budget (Friedlingstein et al., 2020). In this study, the YIBs is used to isolate  
172 impacts of aerosol-induced PAR changes on GPP on the global scale. The model is  
173 driven with  $1^{\circ}\times 1^{\circ}$  meteorological forcing from MERRA-2 reanalyses and PAR (both  
174 diffuse and direct) simulated by CRM model.

175

#### 176 **2.4 Model simulations**

177 We perform 2 GEOS-Chem runs, as well as 22 CRM and YIBs runs to isolate aerosol  
178 direct radiative impacts on GPP at different sky conditions (Supplementary Table 2).  
179 The GEOS-Chem runs GC\_ALL and GC\_NAT are driven with the same meteorology  
180 and emissions except that the former includes all source of emissions while the latter  
181 excludes anthropogenic emissions. The differences between GC\_ALL and GC\_NAT  
182 represent aerosol concentrations contributed by anthropogenic sources. Both GC\_ALL  
183 and GC\_NAT runs provide 3-D concentrations of different aerosol types including  
184 sulfate, nitrate, OC, BC, dust and sea salt. The CRM runs aim to calculate aerosol-  
185 induced PAR changes using aerosol profiles simulated by GEOS-Chem. These runs can  
186 be divided into two groups, with CLD runs (all-sky conditions) forced with observed  
187 cloud profiles while CLR runs (clear-sky conditions) forced without any cloud coverage.  
188 CRM\_ALL and CRM\_NAT are driven with aerosol profiles of all species from  
189 GC\_ALL and GC\_NAT, respectively. The impacts of individual aerosol species on PAR  
190 are isolated with individual aerosol profiles from either GC\_ALL or GC\_NAT. For  
191 example, OC from GC\_ALL and cloud amounts from CERES SYN1deg are used to  
192 drive CRM (CRM\_ALL\_OCCLD) so as to isolate the impacts of OC aerosols on PAR

193 at all-sky conditions. For each of CRM runs, the predicted diffuse and direct PAR are  
194 used as input for YIBs model to simulate GPP changes caused by aerosol DFEs.

195

## 196 **2.5 Observations for model evaluations**

197 We use site-level measurements of carbon fluxes from the FLUXNET2015 product  
198 (<http://fluxnet.fluxdata.org/>) to validate model GPP and its responses to diffuse/direct  
199 radiation. We select 10 sites providing simultaneous observations of diffuse radiation  
200 and GPP at half-hourly time interval for at least 8 years. On the global scale, observed  
201 AOD is retrieved from the Moderate Resolution Imaging Spectroradiometer (MODIS,  
202 <https://modis.gsfc.nasa.gov>) and GPP is derived using global OCO-2-based SIF product  
203 (Li and Xiao, 2019). The all-sky and clear-sky shortwave radiation are adopted from  
204 CERES SYN1deg (<http://ceres.larc.nasa.gov>) to validate the CRM radiative transfer  
205 model.

206

## 207 **3 Results**

### 208 **3.1 Model evaluations**

209 The YIBs model simulates reasonable spatial pattern of GPP compared to  
210 observations (Figure S1) with a high correlation coefficient (R) of 0.88 ( $p < 0.01$ ) and a  
211 low normalized mean bias (NMB) of -2.3%. Similarly, modeled AOD from GEOS-Chem  
212 model reproduces the observed spatial pattern from MODIS product with high R of  
213 0.78 ( $p < 0.01$ ), though overestimates the mean AOD by 21.7% in eastern China and  
214 37.9% in southern Africa while underestimates AOD by 35.7% in Amazon, 25.2% in

215 Central Africa and 53.4% in southeast Asia, leading to a global NMB of -25.8%.

216 The CRM model driven with aerosol concentrations from GEOS-Chem shows  
217 similar patterns of shortwave radiation to the satellite observations (Figure S2). The  
218 simulations match observations well with high R of 0.98 and low NMB of 4.1% at all-  
219 sky conditions, and show even better performance with R of 1 and NMB of 3.7% at  
220 clear skies. Moreover, the CRM model simulates reasonable aerosol direct radiative  
221 effects compared to multiple radiative transfer models as shown in Yue and Unger  
222 (2018).

223 We then compared the simulated and observed GPP responses to direct (diffuse  
224 fraction <0.2) and diffuse radiation (diffuse fraction >0.8) (Figure 1). Observations and  
225 simulations show that diffuse light can increase GPP more efficiently than direct  
226 radiation as shown by the higher GPP-PAR slopes at diffuse conditions. Similar results  
227 were achieved by Mercado et al. (2009) and Yue and Unger (2018) using the same  
228 methods. The diffuse fertilization efficiency, percentage changes in GPP per unit diffuse  
229 PAR, is estimated to be 0.45-0.7%  $W^{-1} m^2$  for observations and 0.3-0.69%  $W^{-1} m^2$  for  
230 simulations. As a result, the YIBs model can reasonably reproduce varied light-response  
231 curves so as to isolate GPP responses to direct and diffuse radiation.

232

### 233 **3.2 Changes of PAR by aerosols**

234 Appearance of aerosols on average decreases total surface PAR by  $1.52 W m^{-2}$  at all  
235 skies and  $2.73 W m^{-2}$  at clear skies on the global scale. Under all-sky conditions,  
236 aerosols increase diffuse PAR by  $1.26 W m^{-2}$  (Figure 2a) but decrease direct PAR by

237  $2.78 \text{ W m}^{-2}$  (Figure S3a). These changes are larger in clear-sky conditions with increase  
238 of diffuse PAR by  $4.98 \text{ W m}^{-2}$  (Figure 2d) and decrease of direct PAR by  $7.71 \text{ W m}^{-2}$   
239 (Figure S3d). The cause of smaller PAR changes at all skies is that cloud tends to  
240 weaken aerosol radiative forcing by amplifying absorption and diminishing scattering  
241 (Paulot et al., 2018).

242 At all-sky conditions, natural aerosols dominate aerosol-induced PAR changes by  
243 increasing diffuse PAR of  $0.93 \text{ W m}^{-2}$  (Figure 2b) and decreasing direct PAR of  $2.05 \text{ W}$   
244  $\text{m}^{-2}$  (Figure S3b). As a comparison, anthropogenic aerosols induce much smaller  
245 changes of diffuse radiation by  $0.33 \text{ W m}^{-2}$  and direct radiation of  $-0.72 \text{ W m}^{-2}$  (Figures  
246 2c and S3c). Natural aerosols mainly influence PAR fluxes in northern Africa owing to  
247 large amount of dust aerosols, while anthropogenic aerosols dominate PAR changes in  
248 eastern China, India, and eastern U.S due to the large anthropogenic emissions. At clear-  
249 sky conditions, natural aerosols increase diffuse PAR by  $3.79 \text{ W m}^{-2}$  (Figure 2e) and  
250 decrease direct PAR by  $5.84 \text{ W m}^{-2}$  (Figure S3e), and anthropogenic aerosols on average  
251 increase diffuse PAR by  $1.19 \text{ W m}^{-2}$  and decrease direct PAR by  $1.88 \text{ W m}^{-2}$ .

252 We further explore the contributions of individual aerosol species to the changes of  
253 diffuse and direct PAR at all skies (Figures S4 and S5). On the global scale, sulfate and  
254 nitrate aerosols increase diffuse PAR by  $0.57 \text{ W m}^{-2}$ , accounting for 51% of aerosol-  
255 induced diffuse PAR changes. Meanwhile, diffuse PAR is increased  $0.05 \text{ W m}^{-2}$ ,  $0.37$   
256  $\text{W m}^{-2}$  and  $0.25 \text{ W m}^{-2}$  by the scattering effects of OC, dust, and sea salt aerosols.  
257 However, BC aerosols reduce diffuse PAR by  $0.06 \text{ W m}^{-2}$  due to the strong absorption.  
258 The changes of direct PAR caused by all aerosol species are negative, especially that

259 by sulfate and nitrate ( $-0.97 \text{ W m}^{-2}$ ), dust ( $-0.86 \text{ W m}^{-2}$ ), and sea salt ( $-0.5 \text{ W m}^{-2}$ ).  
260 Generally, natural aerosols dominate changes of diffuse and direct PAR owing to the  
261 large contributions from dust and sea salt aerosols. However, sulfate, nitrate, and BC  
262 aerosols from anthropogenic sources dominate the changes of diffuse and direct PAR  
263 over eastern China, Indian and eastern U.S.

264

### 265 **3.3 DFE by natural and anthropogenic aerosols**

266 We quantify the percentage changes of global GPP caused by aerosol DFE. On the  
267 global scale, aerosol DFE increases GPP by 0.65 % ( $0.95 \pm 0.13 \text{ Pg C yr}^{-1}$ ) at all skies  
268 (Figure 3a). Relatively high enhancements ( $>2\%$ ) in GPP are found over middle  
269 latitudes ( $20\text{-}50^\circ\text{N}$ ) following the changes of diffuse PAR (Figure 2a). The DFE of  
270 natural aerosols increases global GPP by 0.38% ( $0.56 \pm 0.1 \text{ Pg C yr}^{-1}$ ), mainly over  
271 Middle East and northern Africa due to dust aerosols (Figure S6a and S7g). The DFE  
272 of anthropogenic aerosols increases global GPP up to 0.27 % ( $0.39 \pm 0.04 \text{ Pg C yr}^{-1}$ ),  
273 especially over populous regions including northeast China, Middle East and  
274 contiguous U.S (Figure S6b).

275 At clear skies, aerosol DFE increases global GPP up to 7.8% ( $8.91 \pm 0.26 \text{ Pg C yr}^{-1}$ )  
276 (Figure 3c), which is around 9.5 times of that at all skies (Figure 3a). In most regions,  
277 aerosol DFE increases GPP by more than 4%, with the maximum enhancement of 22.7%  
278 in East Asia. The DFE of natural aerosols enhances global GPP by 4.6%, with large  
279 changes over Amazon, center Africa, boreal Asia, and North America (Figure S6c).  
280 Meanwhile, anthropogenic aerosols increase GPP by 3.2%, mainly located at eastern

281 U.S, Europe, boreal Asia, India and East Asia (Figure S6d).

282 We further quantify the contributions of anthropogenic aerosols to the total aerosol  
283 DFE. Although cloud masks aerosol DFE and significantly reduces GPP enhancement,  
284 the contributions of anthropogenic aerosols remain similar between all-sky (Figure 3b)  
285 and clear-sky (Figure 3d) conditions. Relatively high contributions (>50%) are located  
286 at low-mid latitudes including North America, Europe, and eastern China. Low  
287 contributions (<50%) are found at other regions such as Africa, South America, and  
288 Australia. On the global scale, anthropogenic aerosols on average contribute to 41% of  
289 the total aerosol DFE at all-sky conditions (Figure S6a and S6b). Anthropogenic  
290 aerosols dominate DFE over 30.5% of land grids at all skies, but only 19.5% at clear  
291 skies (Figure 3b and 3d). The most significant differences are located at boreal Europe  
292 where the anthropogenic aerosols make dominant contributions to DFE at clear skies  
293 while the natural species dominate at all skies.

294

### 295 **3.4 DFE by individual aerosol species**

296 We isolate the DFE of individual aerosol species on global GPP (Figures S7 and  
297 S8). At all-sky conditions, sulfate and nitrate aerosols averagely increase GPP by 0.79  
298 Pg C yr<sup>-1</sup>, to which anthropogenic sources contribute 0.58 Pg C yr<sup>-1</sup> (Figure S7f). OC  
299 aerosols increase global GPP by 0.47 Pg C yr<sup>-1</sup>, to which natural sources contribute 0.32  
300 Pg C yr<sup>-1</sup> (Figure S7c). As the dominant natural species, dust and sea salt are generated  
301 from non-vegetated areas. They can increase GPP of downwind land regions by 0.17  
302 Pg C yr<sup>-1</sup> (Figure S7g) and 0.06 Pg C yr<sup>-1</sup> (Figure S7h), respectively. Different from the

303 above species, BC aerosols lead to negative impacts on GPP up to  $-0.28 \text{ Pg C yr}^{-1}$   
304 globally due to the strong absorbing radiative effects. Regionally, such negative effects  
305 are prominent over center Africa from biomass burning (Figure S7a) and eastern China  
306 from anthropogenic emissions (Figure S7b).

307 At clear-sky conditions, scattering aerosols show larger DFE compared to the all-  
308 sky conditions. sulfate and nitrate aerosols increase global GPP by  $5.18 \text{ Pg C yr}^{-1}$ , which  
309 is 6.6 times of that at all skies. The DFE of OC aerosols also largely increase to  $2.89 \text{ Pg}$   
310  $\text{C yr}^{-1}$ , in which  $2.21 \text{ Pg C yr}^{-1}$  is from natural sources. Dust and sea salt aerosols lead  
311 to positive impacts on global GPP by  $1.32 \text{ Pg C yr}^{-1}$  and  $0.48 \text{ Pg C yr}^{-1}$ , respectively. In  
312 contrast, BC aerosols reduce global GPP by  $0.12 \text{ Pg C yr}^{-1}$ , much weaker than the  
313 magnitude of  $0.28 \text{ Pg C yr}^{-1}$  at all skies. Such change mainly follows the larger diffuse  
314 absorption by BC aerosols at all skies ( $0.06 \text{ W m}^{-2}$ ) than that at clear skies ( $0.02 \text{ W m}^{-2}$ ).  
315

316 We then identify the aerosol species making the dominant contributions to the total  
317 aerosol DFE (Figure 4). At all-sky conditions, sulfate and nitrate aerosols lead the DFE  
318 at 65% grids (Figure 4a) and account for 44.7% of the total absolute GPP changes  
319 (Figure 4c). The secondary contribution is from OC aerosols, which account for 26.7%  
320 of the total DFE. Dust and sea salt aerosols contribute to the total DFE by 9.5% and  
321 3.4%, respectively (Figure 4c). BC aerosols exert negative DFE, the absolute value of  
322 which is equivalent to 15.8% of the total DFE. Regionally, sulfate and nitrate aerosols  
323 lead DFE in eastern China, India, eastern U.S., and Europe, while dust aerosols  
324 dominate DFE at Middle East (Figures 4e and 4f). At clear-sky conditions, the

325 percentage contributions of sulfate and nitrate aerosols to the total DFE further increase  
326 to 51.8% on the global scale (Figure 4d). OC, dust, and sea salt aerosols show  
327 comparable contributions to DFE as that at all skies. However, the absolute ratios by  
328 BC aerosols significantly reduce to 1.2%, because BC-induced DFE is limited while  
329 DFE of other species is significantly strengthened at clear skies (Figure S8).

330 We further explore the interannual variations of GPP changes caused by aerosol  
331 DFE from natural and anthropogenic sources (Figure 5). At all-sky conditions, aerosol  
332 DFE significantly ( $p < 0.05$ ) increases by 2.89% yr<sup>-1</sup> (24.6 Tg C yr<sup>-2</sup>) on the global scale  
333 (Figure S9a). Such enhancement is mainly located in northeastern China, India, central  
334 Africa, and Europe (Figure S10a). Natural aerosols lead to a positive trend of 4.7% yr<sup>-1</sup>  
335 in the global GPP (22 Tg C yr<sup>-2</sup>), which is six times of the trend of 0.67% yr<sup>-1</sup> (2.6 Tg  
336 C yr<sup>-2</sup>) from anthropogenic aerosols (Figure 5a). At clear-sky conditions, aerosol DFE  
337 increases by only 0.4% yr<sup>-1</sup> (Figure S9b), much lower than that at all skies (Figure S9a).  
338 Both the DFE trends from natural and anthropogenic aerosols are limited (Figure 5b).  
339 The contrast of DFE trends between different sky conditions is related to the changes  
340 of cloud amount, which shows a significant reduction trend of 0.38% yr<sup>-1</sup> in 2001-2014  
341 (Figure S9c), especially over Amazon and eastern U.S. (Figure S10d). The reduction of  
342 cloud helps increase or maintain aerosol DFE at all-sky conditions (Figure S10c). The  
343 trend of all-sky aerosol DFE is mainly contributed by dust aerosols from natural sources,  
344 which increases by 4.75% yr<sup>-1</sup> during 2001-2014 (Figure 5c). The trend of clear-sky  
345 aerosol DFE is mainly attributed to sulfate and nitrate aerosols, which increase by 0.44%  
346 yr<sup>-1</sup> during 2001-2014 (Figure 5d).

347

## 348 **4 Discussion**

### 349 4.1 Factors influencing aerosol DFE

350 We quantified the impacts of sky conditions, emission sources, and aerosol species  
351 on terrestrial ecosystem productivity through aerosol DFE. In our simulations, aerosols  
352 increase global GPP by 8.91 Pg C yr<sup>-1</sup> at clear skies but only 0.95 Pg C yr<sup>-1</sup> at all skies.  
353 Similarly, Cohan et al. (2002) and Yue and Unger (2017) found aerosol DFE was limited  
354 at cloudy skies. Cloud can mask aerosol DFE by modifying both the quantity and  
355 quality of aerosol radiative perturbations (Yu et al., 2006). First, cloud weakens the  
356 impacts of aerosols on both direct and diffuse radiation (Figure 2 and S3) by reducing  
357 the total sunlight available for the extinction by aerosols (Kinne, 2019). Therefore, the  
358 smaller changes in diffuse PAR by aerosols at all skies (Figure 2) result in lower DFE  
359 than that at clear skies. Second, cloud significantly reduces direct radiation and limits  
360 the potential of increasing GPP by diffuse radiation. Observations have shown an  
361 optimal diffuse fraction of 0.4-0.6 to enhance GPP for most plant types (Zhou et al.,  
362 2021c). A further increase of diffuse fraction above the optimal range will dampen GPP  
363 due to the reduced photosynthesis of sunlit leaves. Appearance of cloud has provided  
364 an environment with high diffuse fraction that aerosols may have limited benefits or  
365 even negative effects for GPP (Yue and Unger, 2017). Such relationship also explains  
366 why the decreasing trend of global cloud amount contributes to an increased aerosol  
367 DFE (Figure 5a).

368 Anthropogenic aerosols account for ~25% of the total aerosol-induced

369 enhancement of diffuse radiation (Figure 2), while they contribute 41% to the total  
370 aerosol DFE at both all and clear sky conditions (Figure 3). The higher efficiency of  
371 anthropogenic aerosols in increasing GPP is partly associated with their geographic  
372 distribution. Regionally, anthropogenic aerosols take a leading role in DFE over North  
373 America, Europe, India, and eastern China, consistent with the estimations by Strada  
374 and Unger (2016). On the other hand, natural aerosols dominate DFE at the tropical  
375 regions. Observations have revealed higher optimal diffuse fraction at higher latitudes,  
376 where the higher solar zenith angle induces larger fraction of shading leaves (Zhou et  
377 al., 2021c). As a result, the same amount of diffuse radiation increased by anthropogenic  
378 aerosols results in higher GPP enhancement at the middle latitudes than natural aerosols  
379 at low latitudes. Furthermore, a dominant fraction of natural aerosols is contributed by  
380 dust and sea salt, which increase diffuse radiation over the barren land or open ocean  
381 with little forest coverage (Figure 2). In contrast, most anthropogenic aerosols locate at  
382 populous regions covered with dense vegetation. Consequently, the diffuse radiation by  
383 anthropogenic aerosols has more interactions with ecosystems than that from natural  
384 sources.

385 Different aerosol species induce varied DFEs to global GPP. Sulfate and nitrate  
386 dominate the aerosols-induced GPP changes (Figure 4) because their strong scattering  
387 effects (Gu et al., 2003) largely increase diffuse radiation (Figure S7 and S8). Keppel-  
388 Aleks and Washenfelder (2016) estimated that the regional reductions of sulfate  
389 aerosols decreased diffuse radiation by  $0.6\% \text{ yr}^{-1}$  and GPP by  $0.07\% \text{ yr}^{-1}$  in eastern U.S.  
390 during 1995-2013. Such negative trends of GPP can also be found over the same region

391 in our clear-sky simulations (Figure S10b). However, the global  $\Delta$ GPP shows limited  
392 trends at clear skies (Figure 5b) because the enhanced  $\text{SO}_2$  emissions in China at the  
393 same period (Hoesly et al., 2018) increased sulfate loading, promoted local GPP (Figure  
394 S10b), and offset the negative  $\Delta$ GPP in eastern U.S. In our simulations, OC aerosols  
395 promote global GPP by  $0.47 \text{ Pg C yr}^{-1}$ . Such magnitude is much lower than the estimates  
396 of  $0.76\text{-}1.61 \text{ Pg C yr}^{-1}$  for the same aerosol species by Rap et al. (2018). The main cause  
397 of such discrepancy is related to the predicted aerosol concentrations and radiative  
398 effects in two studies (Zhou et al., 2021a). Dust and sea salt aerosols increase regional  
399 GPP over arid and coastal regions due to the large local emissions (Yue et al., 2010; Yue  
400 and Liao, 2012). At all skies, dust exerts a large DFE over North Africa and Middle  
401 East (Figure 3a) because of the low cloud coverage (Figure S11). However, such high  
402 GPP ratio shows limited contributions (Figure 4) to global total  $\Delta$ GPP because of the  
403 extremely low baseline GPP in arid regions. Different from above species, BC exerts  
404 negative impacts on direct and diffuse PAR owing to strong absorbing properties  
405 (Kvalevåg and Myhre, 2007). As a result, BC aerosols always decrease GPP with  
406 stronger dampening effects at all skies (Figures 4c and 4d) when the light availability  
407 is much smaller than that at clear skies.

408

#### 409 4.2 Uncertainties

410 Our simulations are subject to limitations and uncertainties. First, biases in aerosol  
411 profiles may influence the derived aerosol DFE. We used the chemical transport model  
412 GEOS-Chem to predict aerosol concentrations and identify contributions from natural

413 and anthropogenic sources. Evaluations showed that GEOS-Chem underestimated  
414 global AOD by 25.8%, especially over Amazon, central Africa, and boreal Asia (Figure  
415 S1) where natural aerosols dominate. Such bias in part explains why Rap et al. (2018)  
416 estimated that biogenic aerosols increased global NPP by  $1.23 \text{ Pg C yr}^{-1}$  with hotspots  
417 over Amazon and central Africa, while our study derived only a moderate enhancement  
418 of  $0.32 \text{ Pg C yr}^{-1}$  by natural OC aerosols. In contrast, simulated AOD is overestimated  
419 in eastern China where anthropogenic sources dominate. In this study, CEDS emission  
420 inventory is used for anthropogenic emissions. Here, we used another emission  
421 database (EDGAR) to assess the uncertainties of DFE from anthropogenic aerosols.  
422 The new simulations showed that anthropogenic aerosols increased global GPP by  $0.31$   
423  $\text{Pg C yr}^{-1}$  (Figures S12-S13), lower than the value of  $0.39 \text{ Pg C yr}^{-1}$  predicted with  
424 CEDS inventory (Figure 3). The spatial patterns of dominant species for aerosol DFE  
425 (Figure S14) remain similar to that from CEDS under both sky conditions.

426       Second, uncertainties in the radiative transfer may cause biases to aerosol DFE.  
427 Although the CRM was fully validated with observations (Figure S2), simulated aerosol  
428 radiative effects showed large differences compared to other studies. For example, Chen  
429 and Zhuang (2014) found that aerosols increased surface diffuse PAR by  $5.2 \text{ W m}^{-2}$   
430 using another radiative transfer model. In our simulations, we estimated that aerosols  
431 increased diffuse PAR by only  $1.26 \text{ W m}^{-2}$ . As a result, the GPP enhancement by aerosol  
432 DFE is  $0.95 \pm 0.13 \text{ Pg C yr}^{-1}$  in our study, much lower than the value of  $4.9 \text{ Pg C yr}^{-1}$   
433 in Chen and Zhuang (2014) though the latter study also considered aerosol-induced  
434 changes in temperature and soil moisture. However, the aerosol radiative effects are

435 likely overestimated in Chen and Zhuang (2014), which predicted total (direct + diffuse)  
436 reductions of  $21.9 \text{ W m}^{-2}$  in surface solar radiation by aerosols; such magnitude is much  
437 higher than the multi-model ensemble estimate of  $-6.3 \text{ W m}^{-2}$  at clear skies (Yu et al.,  
438 2006). As a comparison, our simulations showed a reduction of  $5.8 \text{ W m}^{-2}$  in surface  
439 shortwave radiation, much closer to the ensemble estimates by Yu et al. (2006).

440 Third, we neglected the climatic responses to aerosol radiative effects. Surface  
441 temperature and relative humidity is altered in response to radiative changes caused by  
442 aerosols (Jing et al., 2010; Cirino et al., 2014). The increase of relative humidity can  
443 increase plant photosynthesis owing to the enhancement of water use efficiency (Lu et  
444 al., 2017; Wang et al., 2021), but the impacts of cooling on photosynthesis are dependent  
445 on whether local background temperature is over the optimal temperature (Farquhar et  
446 al., 1980). Moreover, the changes in cloud from aerosol indirect effects were not  
447 considered in this study. Cloud can significantly influence aerosol DFE because of its  
448 strong scattering effects (Figure 3). The perturbations in cloud can further influence  
449 surface temperature, precipitation, and radiation (Zhu et al., 2019), leading to more  
450 complex impacts on terrestrial ecosystem productivity. However, these interactive  
451 effects by aerosols need to be resolved using earth system models that implement fully  
452 coupled atmospheric chemistry, radiation, land biosphere, and climate feedbacks.

453

#### 454 4.3 Implications

455 Our study reveals that aerosol DFE can enhance global GPP by  $0.95 \text{ Pg C yr}^{-1}$  at  
456 all skies and as high as  $8.91 \text{ Pg C yr}^{-1}$  at clear skies. The natural and anthropogenic

457 aerosols make comparable contributions globally but with distinct spatial patterns. The  
458 DFE, as well as the climatic effects, suggests that aerosols play important roles in  
459 mitigating global warming through direct (cooling) and indirect (more carbon  
460 assimilation) processes. Although the reductions of aerosols may weaken the DFE, the  
461 associated reductions of cloud amount due to reduced aerosol-cloud interactions may  
462 induce more benefits to ecosystems. Furthermore, reductions of black carbon aerosols  
463 help relieve both climate warming and GPP inhibitions. Our results suggest that aerosol  
464 DFE should be considered in projecting future changes in terrestrial ecosystem  
465 productivity especially for different emission scenarios.

**Table 1** Summary of previous studies about aerosol DFE

Period	Region	Method	Species	Results <sup>a</sup>	References
2000-2001	Eastern United States	Model	Aerosols	Aerosol DFE decreases NPP by 0.71 g C m <sup>-2</sup> (-0.09%) in 2000 but increases NPP by 5 g C m <sup>-2</sup> (0.5%) in 2001	Matsui et al. (2008)
1960-1999	Global	Model	Cloud and aerosols	DFE enhances the land carbon sink by approximately one quarter during 1960-1999	Mercado et al. (2009)
2002-2003	Amazon	Flux.obs	Smoke aerosols	The increase of CO <sub>2</sub> uptake under high AOD is due to DFE (80%) and decreased temperature (20%)	Doughty et al. (2010)
2007 July–August	Northwest China	Flux.obs	Cloud and aerosols	Cloud dominates DFE, but aerosols lead to negative carbon uptake	Jing et al. (2010)
2003-2010	Global	Model	Aerosols	Aerosol DFE enhances GPP by 4.9 Pg C yr <sup>-2</sup> , NPP by 3.8 Pg C yr <sup>-2</sup> , and NEP by 3.9 Pg C yr <sup>-2</sup>	Chen and Zhuang (2014)
1999-2009	Amazon	Flux.obs	Cloud and fire aerosols	Low AOD and cloud cover lead to relatively larger photosynthetic efficiency than high aerosol loading and thick cloud	Cirino et al. (2014)
1998-2007	Amazon	Model	Fire aerosols	Fire aerosols enhance diffuse radiation by 3.4-6.8% and NPP by 1.4-2.8%	Rap et al. (2015)
2003-2012	Eastern United States	Flux.obs	Aerosols	High AOD (>0.6) enhances plant productivity for forests, but causes negative effects for croplands and grasslands.	Strada et al. (2015)
2000	Global	Model	Aerosols	Aerosol DFE increases global GPP by 1-2%	Strada and Unger (2016)
1995-2013	United States	Model	Sulfate aerosols	The reductions of sulfate aerosols lead to decreased diffuse light by 0.6% yr <sup>-1</sup> and GPP by 0.07% yr <sup>-1</sup>	Keppel-Aleks and Washenfelder (2016)
2010	Amazon	Model	Fire aerosols	Fire aerosols increase GPP by 27%, plant respiration by 10% and decrease soil respiration by 3%	Moreira et al. (2017)
2010-2050	Boreal North America	Model	Fire aerosols	Fire aerosols increase NPP by 8 Tg C yr <sup>-1</sup> at 2010s and 14 Tg C yr <sup>-1</sup> at 2050s due to increased diffuse radiation of 2.6 W m <sup>-2</sup> (1.7%) and 4.0 W m <sup>-2</sup> (2.3%)	Yue et al. (2017)
2009-2011	China	Model	Aerosols	Aerosols increase NPP by 1.6±0.5% at all-sky and 35±0.9% at clear-sky	Yue and Unger (2017)

2008-2017	Eurasia	Flux.obs	Aerosols	High aerosol loading increases GPP by 6-14% at all sites.	Ezhova et al. (2018)
2000	Global	Model	Biogenic aerosols	Biogenic aerosols enhance global NPP by 1.23 Pg C yr <sup>-1</sup> due to DFE	Rap et al. (2018)
2001-2011	Global	Model	All and fire aerosols	All (fire) aerosols increase global GPP by 1.0±0.2 (0.05±0.3) Pg C yr <sup>-1</sup> due to DFE	Yue and Unger (2018)
2014-2015	China	Flux.obs	Aerosols	Photosynthesis of sunlit and shaded leaves increases by 0.56% and 10.71% due to the increase AOD of 0.1	Wang et al. (2018)
2000	Amazon	Model	Fire aerosols	Fire aerosols increase NPP by 5-13 Tg C yr <sup>-1</sup> due to radiative effects	Malavelle et al. (2019)
2018	Western North America	Flux.obs	Wildfire-smoke aerosols	Aerosols lead to GPP enhancement of 1.2-4.1% compared to the previous growing season	Hemes et al. (2020)
2006-2015	China	Model	Aerosols	Aerosols enhance GPP by 0.36 Pg C yr <sup>-1</sup> (5%), and DFE makes the dominant contribution (59-62%)	Xie et al. (2020)

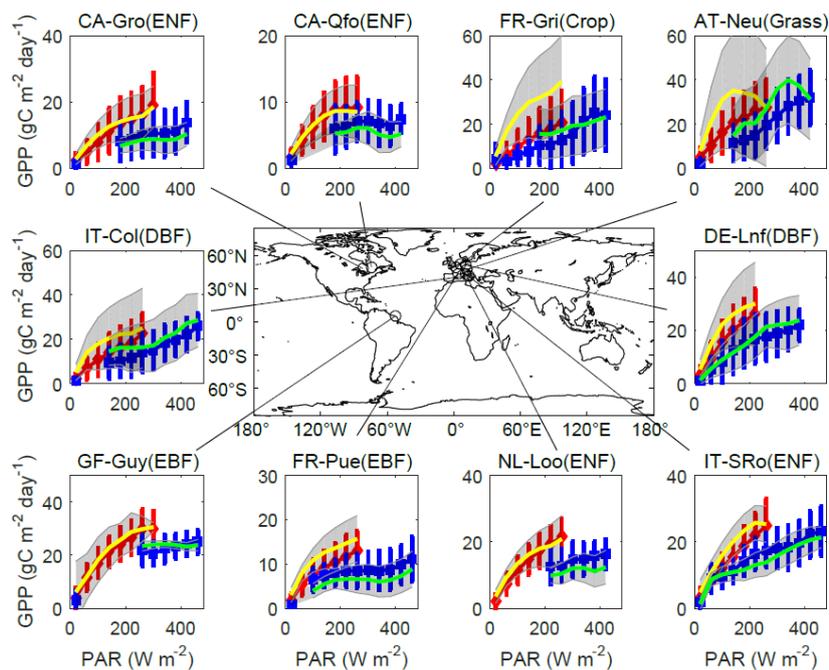

672 <sup>a</sup> Carbon metrics include net primary productivity (NPP), net ecosystem productivity (NEP) and  
 673 gross primary productivity (GPP)

674

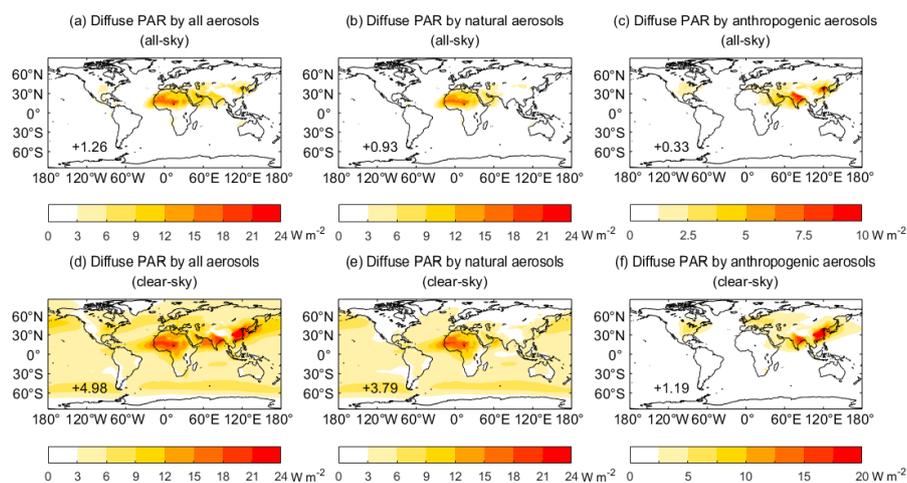

675

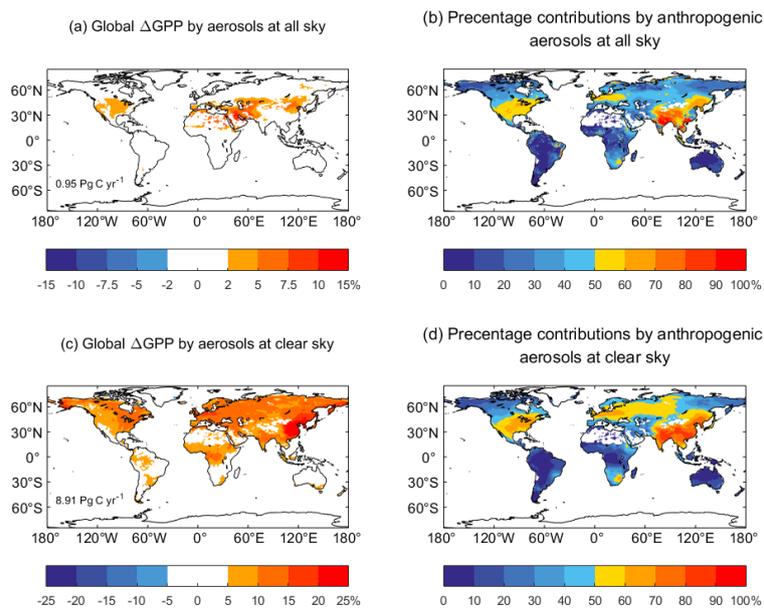

676  
677

678  
679 **Figure 1** Simulated and observed GPP responses to direct and diffuse radiation. The comparisons  
680 are performed at 10 FLUXNET sites where more than 8 years of observations are available. For  
681 each site, hourly observations are divided into direct and diffuse conditions if diffuse fraction is <0.2  
682 (blue squares) and >0.8 (red diamonds), respectively. The classified observations are averaged over  
683 PAR bins of 40 W m<sup>-2</sup> with errorbars indicating one standard deviation of GPP for each bin.  
684 Similarly, simulations are also divided into direct (green) and diffuse (yellow) bins of PAR with  
685 gray shading indicating one standard deviation. The plant function types include evergreen  
686 broadleaf forest (EBF), evergreen needleleaf forest (ENF), deciduous broadleaf forest (DBF),  
687 grassland (Grass), and cropland (Crop). The site name and vegetation type are listed on the title of  
688 each panel.  
689

690  
691 **Figure 2** Global changes of diffuse PAR at surface by all, natural, and anthropogenic aerosols at all  
692 skies (a, b, c) and clear skies (d, e, f). The aerosol species include natural (BC, OC, dust, sea salt,  
693 sulfate, and nitrate) and anthropogenic (BC, OC, sulfate, and nitrate) aerosols. The total changes in  
694 PAR caused by different aerosol sources are shown on corresponding panels. Changes of diffuse  
695 PAR caused by individual aerosol species can be seen in Fig. S4. The units are  $\text{W m}^{-2}$ .  
696

697

698

699

700

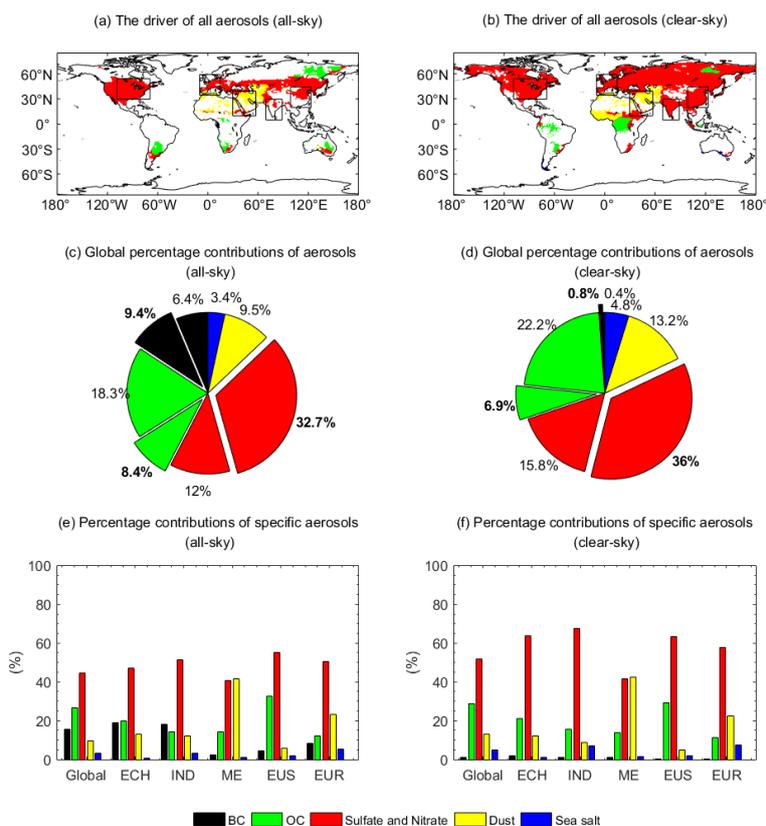

701

702

**Figure 3** Percentage changes in GPP caused by aerosol diffuse fertilization effect and percentage contributions by anthropogenic aerosols at (a, b) all skies and (c, d) clear skies. The DFE of all aerosols (natural + anthropogenic) are shown on the left, and the contributions by anthropogenic aerosols alone are shown on the right.

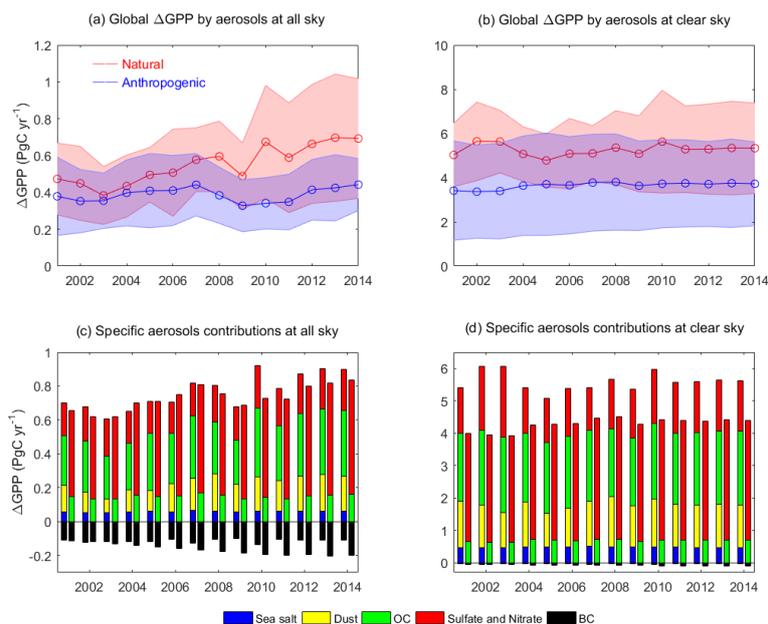

703

704

705 **Figure 4** (a, b) Dominant aerosol species contributing to the simulated changes in GPP and the  
 706 percentage contributions of aerosol species for global (c, d) and specific regions (e, f) at (a, c, e) all  
 707 skies and (b, d, f) clear skies. The contributions in (c, e) and (d, f) are calculated as the ratios of  
 708 absolute DFE, as BC aerosols induce negative DFE. The normal (bold) fonts in (c) and (d) represent  
 709 aerosol species from natural (anthropogenic) sources. Regions with relatively high percentage  
 710 changes in GPP (>1% for all-sky and >5% for clear-sky) by aerosols are shown in Figure (a) and  
 711 (b). The regions include eastern China (ECH), India (INA), Middle East (ME), eastern U.S. (EUS),  
 712 and Europe (EUR), which are marked as black boxes in (a) and (b). The black, green, red, yellow,  
 713 and blue represent the effects of BC, OC, sulfate and nitrate, dust, and sea salt aerosols, respectively.  
 714

715

716 **Figure 5** Interannual variations of GPP changes induced by the DFE of natural and anthropogenic  
717 aerosols at (a, c) all skies and (b, d) clear skies during 2001-2014. The left and right bars at each  
718 year in (c) and (d) represent the effects of natural and anthropogenic aerosol species, respectively.  
719 The hollow circles and shadings in (a) and (b) represent annual mean and standard deviation of  
720 aerosol-induced GPP changes. The black, green, red, yellow, and blue bars indicate the effects of  
721 BC, OC, sulfate and nitrate, dust, and sea salt aerosols, respectively.

722
