9  
10 **Abstract**

11 Nitrogen-containing organic compounds, which may be directly emitted to the  
12 atmosphere or may form via reactions with prevalent reactive nitrogen species (e.g., NH<sub>3</sub>, NO<sub>x</sub>,  
13 NO<sub>3</sub>), have important but uncertain effects on climate and human health. Using gas and liquid  
14 chromatography with soft ionization and high-resolution mass spectrometry, we performed a  
15 molecular-level speciation of functionalized organic compounds at a coastal site on the Long  
16 Island Sound in summer (during the LISTOS 2018 campaign) and winter. This region often  
17 experiences poor air quality due to the emissions of reactive anthropogenic, biogenic, and  
18 marine-derived compounds and their chemical transformation products. We observed a range of  
19 functionalized compounds containing oxygen, nitrogen, and/or sulfur atoms resulting from these  
20 direct emissions and chemical transformations, including photochemical and aqueous-phase  
21 processing that were more pronounced in summer and winter, respectively. In both summer and  
22 winter, nitrogen-containing organic aerosols dominated the observed distribution of  
23 functionalized particle-phase species ionized by our analytical techniques, with 85% and 68% of

30 total measured ion abundance containing a nitrogen atom, respectively. Nitrogen-containing  
31 particles included reduced nitrogen functional groups (e.g., amines, imines, azoles) and common  
32 NO<sub>2</sub> contributors (e.g., organonitrates). The prevalence of reduced nitrogen functional groups  
33 observed in the particle-phase, while frequently paired with oxygen-containing groups elsewhere  
34 on the molecule, often rivaled that of oxidized nitrogen groups detected by our methods.  
35 Supplemental gas-phase measurements, collected on adsorptive samplers and analyzed with a  
36 novel liquid chromatography-based method, suggest that gas-phase reduced nitrogen compounds  
37 are possible contributing precursors to the observed nitrogen-containing particles. Altogether,  
38 this work highlights the prevalence of reduced nitrogen-containing compounds in the less-  
39 studied Northeastern U.S., and potentially in other regions with similar anthropogenic, biogenic,  
40 and marine source signatures.

## 42 1. Introduction

43 Coastal regions near the Long Island Sound often experience poor air quality due to a  
44 combination of biogenic and anthropogenic emissions from upwind metropolitan areas along the  
45 East Coast of the U.S. It is well established that these emissions undergo chemical  
46 transformations to form secondary pollutants during hours to days of over-water transport to  
47 downwind locations, including the states of Connecticut, Rhode Island, and Massachusetts (e.g.,  
48 Cleveland et al., 1976). Emissions of gas-phase organic compounds (e.g., volatile, intermediate,  
49 and semi-volatile organic compounds (VOCs, IVOCs, SVOCs)) and primary organic aerosols  
50 (POA) are oxidized via numerous pathways in the atmosphere to yield ozone (O<sub>3</sub>) and secondary  
51 organic aerosol (SOA) (Hallquist et al., 2009). SOA constitutes a variable but significant fraction  
52 of particulate matter with a diameter of 2.5 μm or less (i.e., PM<sub>2.5</sub>). Both O<sub>3</sub> and PM<sub>2.5</sub> are of

54 particular concern for human health and climate; O<sub>3</sub> is known to cause an increase in respiratory-  
55 related illnesses (Di et al., 2017; Jerrett et al., 2009), while PM<sub>2.5</sub> is known to cause adverse  
56 cardiovascular, respiratory, and cognitive effects and to impact climate forcings (Di et al., 2017;  
57 Hallquist et al., 2009; Kilian and Kitazawa, 2018; Pope and Dockery, 2006). Coupled with local  
58 emissions and chemistry, these incoming aged air parcels from coastal metropolitan areas  
59 contribute to the Long Island Sound region often entering nonattainment for O<sub>3</sub> (United States  
60 Environmental Protection Agency, 2020), especially in the summer.

61 The chemistry and composition of organic compound emissions and secondary  
62 transformation products in the Long Island Sound area is historically understudied, though some  
63 past work has advanced our understanding of important sources and chemical pathways in the  
64 region. For example, VOC and sub-micron particulate matter composition were investigated  
65 during the 2002 New England Air Quality Study (de Gouw et al., 2005), with further VOC  
66 speciation in 2004 during the New England Air Quality Study – Intercontinental Transport and  
67 Chemical Transformation campaign (Warneke et al., 2007). More recently, a 2015 aircraft  
68 campaign in the Northeast U.S. called WINTER characterized wintertime chemistry in the region  
69 and also investigated organic aerosol formation via aerosol mass spectrometry (Schroder et al.,  
70 2018). Finally, the LISTOS campaign in 2018 focused on measuring and modeling O<sub>3</sub> mixing  
71 ratios over the Sound to investigate the dynamics of O<sub>3</sub> formation linked to large metropolitan  
72 areas along the coast and associated downwind impacts (Zhang et al., 2020).

73 However, little is known about the molecular-level chemical composition of the gas-  
74 phase I/SVOCs and functionalized organic aerosol formed in the Northeastern U.S. This  
75 molecular-level speciation is key to understanding the physical/chemical properties of these  
76 compounds in the atmosphere and their chemical transformations, especially for classes of

77 compounds containing reduced and oxidized nitrogen functional groups, whose emissions,  
78 lifetime, and ultimate impacts are generally poorly understood. For example, nitrogen-containing  
79 compounds that serve as reservoir species for nitrogen oxides may increase the overall lifetime  
80 of nitrogen oxides in the atmosphere via renoxification mechanisms (e.g., the photolysis of  
81 particulate nitrates, which has been studied in the marine boundary layer (Ye et al., 2016)); some  
82 may act as light absorbing chromophores (e.g., the brown carbon studied from a methylglyoxal  
83 and ammonium sulfate system, which yielded mostly N-containing chromophores (Lin et al.,  
84 2015)); and some may have adverse, but uncertain, effects on human health (e.g., impacts on  
85 immune response to allergens (Ng et al., 2017)).

86 [There have been a wide range of measurements of organic nitrogen in the atmosphere,](#)  
87 [and many past studies have emphasized enhancements in the contribution of this organic](#)  
88 [nitrogen in various forms of water in the atmosphere such as cloud water, fog water, rain water,](#)  
89 [and aerosol liquid water. For example, in cloud water, observations of important contributions](#)  
90 [from nitrogen- and oxygen-containing organic compounds have been made using Fourier-](#)  
91 [transform ion cyclotron resonance mass spectrometry \(FT ICR-MS\) \(Zhao et al., 2013\). Across](#)  
92 [all the oxygenates \(i.e., CHO\), oxygen- and nitrogen-containing compounds \(CHON\), oxygen-](#)  
93 [and sulfur-containing compounds \(CHOS\), and oxygen-, nitrogen-, and sulfur-containing](#)  
94 [compounds \(CHONS\) that Zhao et al. \(2013\) observed in cloud water, roughly 65% of ions \(by](#)  
95 [number count\) contained a nitrogen atom. Roughly half of all species observed were CHON](#)  
96 [compounds. Also, roughly half of the CHON species had low O/C \(<0.7\), and were hypothesized](#)  
97 [to contain reduced nitrogen functional groups. Another example from a study in the Southeastern](#)  
98 [U.S. by Boone et al. \(2015\) showed that cloud water samples contained a large fraction of](#)  
99 [nitrogenated species relative to aerosol-phase samples. From a combination of direct infusion](#)

100 [electrospray ionization and nanospray desorption electrospray ionization measurements with](#)  
101 [high resolution mass spectrometry](#). Boone et al. (2015) observed roughly four times more CHON  
102 [molecular formulas in cloud water than in particle-phase samples, representing ~20% of all ions,](#)  
103 [by number count, in cloud water. They also suggested an important role for aqueous-phase](#)  
104 [reactions occurring between water-soluble oxygenated organic compounds and a diversity of](#)  
105 [nitrogen-containing species such as ammonium, nitrate, small amines, among others \(Boone et](#)  
106 [al., 2015\).](#)

107 [Similar observations have been made in fog water samples. For example, LeClair et al.](#)  
108 [\(2012\) discussed the importance of water-soluble organic nitrogen-containing compounds in fog](#)  
109 [water using FT ICR-MS. Roughly half of their observed compounds contained a nitrogen atom,](#)  
110 [and by tracking neutral losses, they identified that 50-83% of their observed CHON species](#)  
111 [showed a neutral loss of HNO<sub>3</sub> and thus likely contained a nitrate group. They noted that in the](#)  
112 [absence of HNO<sub>3</sub>, CH<sub>3</sub>NO<sub>3</sub>, NO, or NO<sub>2</sub> losses, the remaining nitrogen-containing ions observed](#)  
113 [likely contained reduced nitrogen groups such as amine, amino, or imine structures \(LeClair et](#)  
114 [al., 2012\). Another study of fog droplets with aerosol mass spectrometry by Kim et al. \(2019\)](#)  
115 [showed an enrichment of organic nitrogen in fog droplets, including observations of reduced](#)  
116 [nitrogen groups such as imidazoles and pyrazines \(Kim et al., 2019\). They observed fog water's](#)  
117 [N/C ratio to be roughly 4 times greater than the N/C ratio in oxygenated organic aerosol samples.](#)

118 [These trends extend to rain water as well; FT ICR-MS measurements of rainwater in the](#)  
119 [Northeastern U.S. by Altieri et al. \(2009\) showed large contributions of nitrogen-containing](#)  
120 [organic compounds \(Altieri et al., 2009\). Approximately 70% of their observed nitrogen-](#)  
121 [containing species were CHON species from positive mode ionization, which they suggested](#)  
122 [consisted largely of reduced nitrogen functional groups based on their detection in positive](#)

123 ionization mode and based on their elemental ratios. Similar enhancements in bulk organic  
124 nitrogen, made by measuring total nitrogen content and subtracting the contribution from  
125 inorganic nitrogen, were noted in both rain water and aerosols collected on the Mediterranean  
126 coast (Mace et al., 2003a), and in both rain and cloud water in a Caribbean background marine  
127 environment (Gioda et al., 2011).

128 While Boone et al. (2015) showed enhanced nitrogen content in cloud water relative to  
129 aerosol particles, aerosol-phase samples have also been observed in other studies across the  
130 globe to contain high organic nitrogen content. For example, at another location in the  
131 Southeastern U.S. with strong marine and continental air influence, Lin et al. (2010) observed  
132 that organic nitrogen in PM<sub>2.5</sub> contributed roughly 33% of total PM<sub>2.5</sub> nitrogen mass, which they  
133 computed by subtracting inorganic nitrogen contributions from total nitrogen content, as  
134 mentioned above (Lin et al., 2010). Similarly, 61% of primary marine aerosols (magnitude-  
135 weighted) collected from a ship in the Atlantic ocean and analyzed by FT ICR-MS were shown  
136 to contain nitrogen, and 54% of these primary marine aerosol species were CHON compounds,  
137 with the remaining 7% of nitrogen content distributed across CHONS and CHONP species  
138 (Wozniak et al., 2014). These primary marine aerosols typically had O/C ratios less than 0.5 and  
139 were also likely reduced nitrogen-containing, consistent with Zhao et al. (2013). Other examples  
140 include bulk organic nitrogen measurements from aerosols collected inland during both the wet  
141 and dry seasons in the Amazon basin (Mace et al., 2003b), from aerosols sampled in Davis,  
142 California (Zhang et al., 2002), and from aerosols (and fog) in the Po Valley in Italy (Montero-  
143 Martinez et al., 2014).

144 Finally, a recent study of aerosols collected in a forest in Tokyo highlighted the role of  
145 aerosol liquid water as another important medium for the formation of water soluble organic

146 [nitrogen-containing species, and showed a positive correlation between the concentration of](#)  
147 [aerosol liquid water and water-soluble organic nitrogen \(Xu et al., 2020\).](#)

148 [Considering the coastal nature of our Long Island Sound site and general prevalence of](#)  
149 [water in the local/regional atmosphere \(e.g., as cloud water, fog water, rain water, and aerosol](#)  
150 [liquid water\), the overall goal of this study was to examine](#) the composition and contributions of  
151 nitrogen-containing organic compounds from mixed anthropogenic, biogenic, and marine  
152 sources, [as well as the possible roles of secondary product formation via aqueous-phase](#)  
153 [chemistry. We collected samples of organic gases and particles for detailed chemical speciation](#)  
154 on the coast of the Long Island Sound in Guilford, Connecticut. We note that we used this site as  
155 a case study, but our observations of emissions and chemistry at this site are likely informative  
156 for other coastal urban and downwind regions due to the ubiquity of nitrogen-containing  
157 emissions from [anthropogenic, biogenic, and marine sources](#).

158 Samples were collected during the summer and winter, and analyzed via high resolution  
159 mass spectrometry to speciate the complex mixture of emissions and chemical transformation  
160 products. These samples were taken alongside several targeted pollutant measurements including  
161 O<sub>3</sub>, nitrogen oxides (NO<sub>x</sub>), particulate matter with a diameter of ≤ 2.5 μm (PM<sub>2.5</sub>), and black  
162 carbon (BC), all to inform our chemically-speciated analyses, and to contribute to a longer-term  
163 characterization of this coastal area.

164 The [specific](#) objectives of this study were to: (1) investigate compositional [differences](#)  
165 and possible chemical pathways contributing to measured summer and winter functionalized  
166 organic aerosols at this site; (2) examine the relative contributions of reduced and oxidized  
167 nitrogen groups to functionalized organic aerosol; and (3) use a novel sampling and liquid  
168 chromatography-based analytical approach to probe the molecular-level composition of

175 functionalized gas-phase organic compounds and investigate possible nitrogen-containing gas-  
176 phase precursors to the observed reduced nitrogen-containing particles.

177

## 178 2. Materials and Methods

179 We collected measurements at the Yale Coastal Field Station (YCFS) in Guilford,  
180 Connecticut (41.26°N, 72.73°W) (Rogers et al., 2020). Inlets were positioned facing the Long  
181 Island Sound (i.e., South-Southeast) to capture onshore flow. The YCFS often received aged  
182 urban incoming air from East Coast metropolitan areas, similar to known common air parcel  
183 trajectories in the region (Figure S1). However, due to extensive mixing in the Northeast corridor  
184 and over the Long Island Sound, along with extended collection times for offline gas- and  
185 particle-phase samples, we also observed considerable biogenic and anthropogenic influence  
186 from other areas of the Northeastern U.S.

187

### 188 2.1. Offline Samples of Organic Particles and Gases Analyzed via Liquid and Gas

#### 189 Chromatography with Mass Spectrometry

190 We discuss three types of sampling and quadrupole time-of-flight mass spectrometry-  
191 based analyses here: particles collected on Teflon filters and analyzed using liquid  
192 chromatography with electrospray ionization, gases collected on packed adsorbent tubes and  
193 analyzed using gas chromatography with atmospheric pressure chemical ionization, and  
194 functionalized gases collected on cooled polyether ether ketone (PEEK) samplers and analyzed  
195 using liquid chromatography with electrospray ionization. Teflon filter and adsorbent tube  
196 measurements were collected at the YCFS during the summer as part of the 2018 Long Island  
197 Sound Tropospheric Ozone Study (LISTOS), from July 9 to August 29, 2018. Additional filter

Deleted:

199 and adsorbent tube samples were collected during the following winter from February 25 to  
200 March 5, 2019. Supplemental wintertime gas-phase samples on PEEK tubing were collected  
201 briefly from March 5-6 2020, prior to the COVID-19 shutdown. [These sampling periods are](#)  
202 [discussed here as summer and winter case studies but longer campaigns are warranted to assess](#)  
203 [full seasonal trends.](#)

204 [A custom filter and adsorbent tube housing was constructed](#) to simultaneously collect  
205 particle- and gas-phase organic compounds, respectively (Sheu et al., 2018). The filter was  
206 positioned immediately upstream of the adsorbent tube to collect particles for analysis and to  
207 prevent particles from reaching the gas-phase [adsorbent tube](#) sample. The housing was designed  
208 to minimize spacing between the filter and adsorbent tube to reduce gas-phase losses to upstream  
209 surfaces, and was built out of a modified passivated stainless steel filter holder ([Pall](#)) and an  
210 aluminum block with sealed 6.34 mm (1/4") holes for adsorbent tubes (Sheu et al., 2018).

211 [For filter and adsorbent tube collection, we used a short inlet \(0.9 m long, 5/8" OD](#)  
212 [stainless steel tubing, positioned 2.5 m above the ground\) upstream of the custom sampler to](#)  
213 [allow the sampling media to be housed in an air-conditioned trailer. A stainless steel mesh screen](#)  
214 [\(84 mesh\) was used at the opening of the inlet to limit particle size to ~PM<sub>10</sub> and to prevent large](#)  
215 [particles from entering the sampler \(Ditto et al., 2018\). Penetration efficiency through the mesh](#)  
216 [screen was computed for the 20 L/min flow rate using the screen thickness, mesh size \(84 mesh\),](#)  
217 [wire diameter, and accounting for the effects of diffusion, impaction, and interception. Based on](#)  
218 [this modeling, we expect roughly 50% penetration efficiency at PM<sub>10</sub> and 0% at PM<sub>11</sub> and larger.](#)

**Deleted:** ¶

For filter and adsorbent tube collection, we used a short inlet (0.9 m long, 5/8" OD stainless steel tubing, positioned 2.5 m above the ground) upstream of the custom the sampler to allow the sampling media to be housed in an air-conditioned trailer. A stainless steel mesh screen (84 mesh) was used at the opening of the inlet to limit particle size to ~PM<sub>10</sub> and to prevent large particles from entering the sampler (Ditto et al., 2018). P.

**Deleted:** connected to the inlet

232 [2.1.1. Filter sampling, analysis, and data QA/QC](#)

233 Teflon filters (47 mm, 2.0  $\mu\text{m}$  pores, Tisch Scientific) were used for particle-phase  
234 sampling. Filters were collected at 20 L/min for 8 hours, during the day (9:00am-5:00pm) and at  
235 night (9:00pm-5:00am). Samples were extracted in methanol and analyzed via liquid  
236 chromatography (LC) using an Agilent 1260 Infinity LC and an Agilent Poroshell 120 SB-Aq  
237 reverse phase column (2.1 x 50 mm, 2.7  $\mu\text{m}$  particle size). The LC was coupled to an  
238 electrospray ionization (ESI) source and a high-resolution mass spectrometer (Agilent 6550 Q-  
239 TOF), and operated following previously described methods (Ditto et al., 2018, 2020). [The mass  
240 resolution \(M/ \$\Delta\$ M\) of the Q-TOF used in this work was  \$\geq 25,000\$ -40,000, and the mass accuracy  
241 was 1-2 ppm. Our use of LC \(or GC\) to separate compounds prior to their ionization and  
242 detection by the mass spectrometer reduced mass spectral interferences and thus enabled  
243 accurate molecular formula assignments beyond what would be possible by relying on the Q-  
244 TOF's mass resolution alone.](#)

245 Filter extracts were run with MS (i.e., TOF-only, to identify molecular formulas) and  
246 MS/MS (i.e., tandem mass spectrometry, to identify functional groups) data acquisition, using  
247 both positive and negative mode electrospray ionization. These methods are hereafter referred to  
248 as “LC-ESI-MS” and “LC-ESI-MS/MS”, respectively. Acquisition and non-targeted analysis  
249 methods, including data [quality assurance and quality control \(QA/QC\)](#), are discussed in past  
250 work (Ditto et al., 2018, 2020). [Briefly, for LC-ESI-MS analyses, any ion mass appearing in both  
251 a sample and its corresponding blank \(matching ion mass with a tolerance of 5 ppm, and  
252 matching ion retention time with a tolerance of 0.25 min—both tolerances were chosen to be  
253 quite conservative\) was removed if its abundance in the sample was less than 5 times its  
254 abundance in the blank. Ions with greater sample:blank ratios were retained, and the abundance](#)

255 of the blank peaks were subtracted from the sample peaks. Positive and negative ionization mode  
256 data were combined and any ions appearing in both modes were flagged; abundances were  
257 averaged and the compound was only counted once. Ions from m/z 50-600 were assigned  
258 formulas assuming hydrogen or sodium adducts in positive mode and acetate adducts or  
259 deprotonation in negative mode. We also allowed for the neutral loss of water. Only peaks that  
260 well-surpassed instrument noise and that had strong peak quality scores (based on both liquid  
261 chromatography and mass spectrometry data) were selected for formula identification according  
262 to thresholds detailed in Ditto et al. 2018. Formulas were assigned with the following elemental  
263 constraints in Agilent's Mass Hunter software:  $C_{3-60}H_{4-122}O_{0-20}N_{0-3}S_{0-3}$ , minimizing the ppm  
264 mass difference between the observed and proposed ion mass and accounting for isotope  
265 distribution. Prior to non-targeted analysis, further QA/QC was performed on these formula  
266 identifications using custom R code. As discussed by Kind and Fiehn (2007), the number of  
267 elements was further constrained to 39 carbons and 72 hydrogens, and H/C ratios were checked  
268 to ensure they fell within expected limits ( $0.2 < H/C < 3.1$ ) (Kind and Fiehn, 2007). Formulas  
269 were then screened to ensure they agreed with the Nitrogen rule, to ensure that all double bond  
270 equivalent values were integers, and to flag any large mass differences ( $>7$  ppm) between the  
271 observed and proposed mass for a given molecular formula.

272 For MS/MS, any ions from the LC-ESI-MS analyses that passed these QA/QC steps were  
273 targeted for MS/MS fragmentation at 5, 10, 20, 30 and 40 V. We used SIRIUS with  
274 CSI:FingerID for functional group identification with a subset of compounds from MS analysis  
275 (Dührkop et al., 2015, 2019), as detailed in past work (Ditto et al., 2020). We assumed the same  
276 ionization behavior as discussed above, with the same elemental composition constraints and a  
277 conservative 7 ppm mass tolerance. Functional groups for the top-scoring candidate structure for

278 [each ion were tallied with APRL Substructure Search Program](#) (Ruggeri and Takahama, 2016).  
279 [The exact position of each functional group was not considered, as the focus of our work was](#)  
280 [instead to assess the presence or absence of atmospherically relevant functional groups and their](#)  
281 [combinations across a large number of multifunctional compounds.](#)

282 After stringent QA/QC for peak shape and accurate molecular formula determination,  
283 non-targeted compound identification from LC-ESI-MS [identified](#) an average of  $200 \pm 56$  and  
284  $167 \pm 47$  compounds per sample analyzed in summer and winter, respectively, across 34 samples  
285 in summer and 15 in winter. [v](#)

286 We note that filter ion abundance data is presented as combined positive and negative  
287 ionization mode data, [which treats the compounds equally without corrections for](#) ionization  
288 efficiency. [As mentioned above, compounds were not double counted; any ion appearing in both](#)  
289 [positive and negative mode was flagged, its average abundance computed, and it was tallied only](#)  
290 [once.](#) While ionization efficiency differences between compound types exist, their [exact](#) effects  
291 for multifunctional compounds present in a complex mixture are uncertain. Thus, similar to other  
292 studies and to our past work, we treat the intercomparison across compounds [without adjusting](#)  
293 [for ionization efficiency differences](#) (Ditto et al., 2018). [We note that the figures in the main text](#)  
294 [are displayed as fractions of total observed ion abundance, to consider variations in atmospheric](#)  
295 [abundance across the complex mixture of functionalized species. However, due to uncertainty in](#)  
296 [exact ionization efficiency, these are not intended to directly represent mass concentration. For](#)  
297 [comparison, identical figures represented by occurrence \(i.e., unweighted by abundance\) are](#)  
298 [presented in the SI \(Figures S4-S6, S8-S9, S11, S13\); general observations remain similar](#)  
299 [between abundance weighted and occurrence results.](#)

Deleted: examined

Deleted: For MS/MS, we used SIRIUS with CSI:FingerID for functional group identification with a subset of compounds from MS analysis (Dührkop et al., 2015, 2019), as detailed in past work (Ditto et al., 2020).

Deleted: ies

307 [2.1.2. Adsorbent tube sampling, analysis, and data QA/QC](#)

308 Gas-phase samples were collected on glass adsorbent tubes (6.35 mm OD, 88.9 mm long)  
309 packed with quartz wool, glass beads, Tenax TA, and Carboxen 100 (Sheu et al., 2018). Samples  
310 were collected at 200 mL/min for 2 hours, [sub-sampling off of the 20 L/min filter flow](#), during  
311 the day (2:00-4:00pm) and at night (2:00-4:00am). Adsorbent tubes were analyzed using a  
312 GERSTEL TD3.5+ thermal desorption unit and an Agilent 7890B gas chromatograph (GC) with  
313 a DB5-MS UI column (30 m x 320  $\mu$ m x 0.25  $\mu$ m). The GC was coupled to an atmospheric  
314 pressure chemical ionization (APCI) source and the same Q-TOF as above, operated with MS  
315 (i.e., TOF-only) data acquisition and positive ionization mode only. These methods are hereafter  
316 called “GC-APCI-MS” and acquisition and analysis methods are discussed in past work (Ditto et  
317 al., 2021; Khare et al., 2019). After QA/QC ([as detailed in Section 2.1.1](#)), this non-targeted  
318 analysis yielded an average of 388 $\pm$ 201 and 612 $\pm$ 133 compounds per sample in summer and  
319 winter, respectively, across 34 samples in summer and 14 samples in winter.

320  
321 [2.1.1. PEEK collector sampling, analysis, and data QA/QC](#)

322 Finally, as a supplemental analysis to probe the composition of functionalized gases that  
323 were not GC amenable and thus not measured using the adsorbent tube and thermal desorption-  
324 gas chromatography techniques mentioned above, we used PEEK-based sample collectors and  
325 liquid chromatography to trap and speciate oxygen-, nitrogen-, and/or sulfur-containing gases  
326 without thermal desorption. This method was designed to target functionalized gases, which  
327 represent important precursors, intermediates, and by-products in the atmospheric processing of  
328 emitted organic compounds but are often challenging to speciate with traditional GC techniques  
329 due to their chemical functionality, reactivity, and/or thermal lability. Additionally, in many gas-

330 phase measurement systems, primary emissions (i.e., hydrocarbons) can overwhelm the signal of  
331 more functionalized analytes, adding to the challenge of speciating these lower abundance  
332 compounds.

333 Thus, to probe the chemical composition of these functionalized gases, we used a  
334 sampling approach, desorption method, separation method, and ionization technique that  
335 leveraged their relatively lower volatility and higher polarity. This included adsorptive sampling  
336 onto cooled PEEK tubing followed by direct inline desorption into the LC mobile phase for LC-  
337 ESI-MS analysis. ESI was specifically chosen here because it is sensitive to functionalized  
338 compounds. Testing was performed in positive and negative ionization mode, but field samples

339 were run in positive mode only. [Further details and discussion of this method, including method](#)  
340 [development and evaluation](#), can be found in Section S1 and Tables S1-3. [Briefly](#), PEEK tubing

341 was cooled to 2°C and used as an adsorptive collector, with a Teflon filter positioned upstream  
342 of the PEEK tubing to remove particles. PEEK was selected due to its inert behavior, thus  
343 reducing the possibility for surface-analyte interactions that might inhibit effective inline solvent  
344 desorption and dissolution. PEEK is also compatible with the solvents used in the LC system,  
345 and is frequently used in LC instruments. Field samples were collected on cooled PEEK tubing  
346 during the subsequent winter (March 5-6, 2020), for 2 hours each between 8:00am-2:00pm. For  
347 these 2 hour (~2.6 L) field samples, functionalized gases in a typical 100-250 g/mol molecular  
348 weight range were resolvable at ~25-60 ppt in the atmosphere, based on instrument detection  
349 limits (Ditto et al., 2018). For analysis, each PEEK collector was installed in the LC system flow  
350 path, and analytes were directly desorbed using the LC mobile phase solvents then trapped and  
351 focused on the LC column for 20 minutes, before being analyzed using the same LC-ESI-MS  
352 system in positive ionization mode (Figure 1). This inline mobile phase desorption step gently

Deleted: While

Deleted: f

Deleted: , b

356 mobilized potentially fragile analytes from the PEEK collector and trapped and focused them on  
357 the LC column prior to chromatographic separation and mass spectral analysis. Additionally, this  
358 preconcentration step allows for the detection and characterization of lower concentration  
359 species. [Data were processed and QA/QC were performed as detailed in Section 2.1.1.](#)

360 We note that there are other existing approaches for offline collection of highly-  
361 functionalized organic gases and particles that are compatible with LC analysis such as spray  
362 chambers, particle into liquid samplers, coated denuders, PUF sampling, and more. This PEEK  
363 sampling method with inline desorption into the LC mobile phase was pursued to reduce sample  
364 preparation steps and thus possibilities for losses (e.g., during solvent extraction or evaporative  
365 preconcentration), as well as for its direct similarity to the filter-based particle-phase LC-ESI-MS  
366 analysis.

367 We also note that for all [filter collection and LC analyses \(filters and PEEK collectors\)](#), it  
368 is possible that some functional groups of interest [may have undergone hydrolysis on the filter](#)  
369 [during 8-hour filter collection periods or](#) in the LC mobile phase, which was primarily water at  
370 the beginning of the LC solvent gradient. [For example, organonitrates may be susceptible to](#)  
371 [hydrolysis depending on their structure; tertiary organonitrates can undergo hydrolysis on the](#)  
372 [timescale of minutes-hours depending on pH, while primary/secondary organonitrates are](#)  
373 [relatively stable. Hydrolysis occurs more quickly at low pH. The pH of the LC mobile phase \(pH](#)  
374 [~ 2\) and the pH of the sampled aerosol \(pH < ~5, \(Pye et al., 2020\)\) are both acidic; alpha-](#)  
375 [pinene-derived organonitrates, for example, could have a lifetime of as low as of roughly 8](#)  
376 [minutes to 1.5 hours across this pH range](#) (Rindelaub et al., 2016). [If hydrolysis occurred, some](#)  
377 of the observed compounds could be byproducts of other functionalized species. While we did

383 not observe any of our nitrogen-containing test standards to hydrolyze over these timescales,  
384 standards were not available to reflect every functional group observed in these datasets.

385

## 386 2.2. Supporting Measurements

387 O<sub>3</sub>, NO<sub>x</sub>, PM<sub>2.5</sub>, and BC concentrations were recorded concurrently during both summer  
388 and winter sampling periods. O<sub>3</sub> was measured with a 2B Tech Model 202 Ozone Monitor, NO<sub>x</sub>  
389 with a Thermo Scientific Model 42i-TL Analyzer, PM<sub>2.5</sub> with a MetOne BAM-1020 instrument,  
390 and BC with a Magee Scientific AE33 Aethalometer. O<sub>3</sub> and NO<sub>x</sub> inlets were constructed of FEP  
391 tubing (1/4" OD), with a Teflon filter housed in a PFA filter holder upstream to remove particles.  
392 The PM<sub>2.5</sub> inlet was made of stainless steel tubing (1 1/4" OD) and the BC inlet was made of  
393 copper tubing (3/8" OD). Both particle inlets were outfitted with a PM<sub>2.5</sub> cyclone to limit particle  
394 size to 2.5 μm and below.

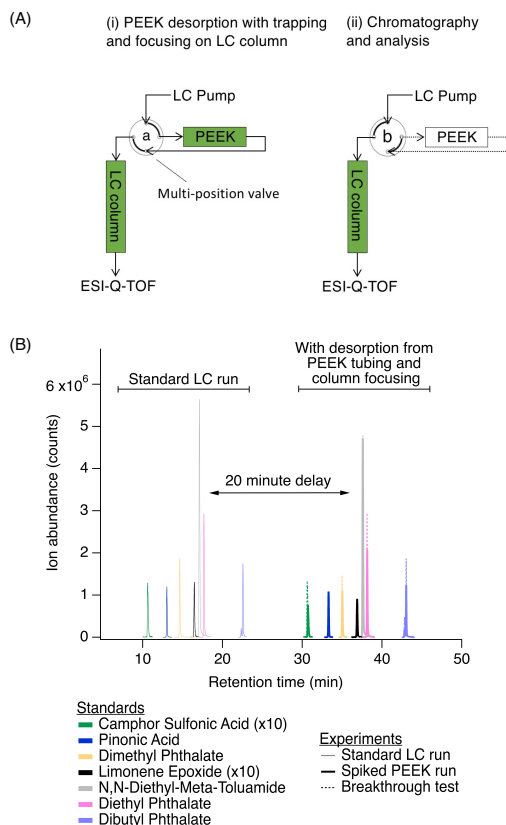

395 All inlets were mounted 3 m above the ground. Instrument flow rates were calibrated  
396 with an external mass flow controller. O<sub>3</sub> and NO<sub>x</sub> monitors were zeroed with laboratory-  
397 generated zero air. The O<sub>3</sub> monitor was calibrated against Connecticut Department of Energy and  
398 Environmental Protection instrumentation and further confirmed with an O<sub>3</sub> generator in the lab.  
399 The NO<sub>x</sub> monitor was calibrated using a NO standard (AirGas, 2 ppm NO in nitrogen, ± 5%)  
400 diluted to 25 ppb with laboratory-generated nitrogen gas. The BC instrument was programmed to  
401 conduct an automatic performance check using particle-free air and the PM<sub>2.5</sub> instrument was  
402 zeroed following MetOne protocols with particle-free air. O<sub>3</sub> and NO<sub>x</sub> data were collected at 1-  
403 second intervals, BC data were collected at 1-minute intervals, and PM<sub>2.5</sub> data were collected at  
404 1-hour intervals. BC data were saved directly from the instrument, while O<sub>3</sub>, NO<sub>x</sub>, and PM<sub>2.5</sub>  
405 data were recorded with a LabJack T7 datalogger and custom LabView code. In addition, hourly

406 weather data (temperature, relative humidity, wind speed, wind direction) were collected with a  
407 WeatherHawk weather station on top of the 3 m tower.

408 During the summer, we also collected a small number of size-resolved particle samples  
409 on quartz filters using an eight-stage cascade impactor (Thermo Scientific [Andersen Non-Viable](#)  
410 [Cascade Impactor](#)). Sizes ranged from 0.43-10.0  $\mu\text{m}$  (stage 0: 9.0-10.0  $\mu\text{m}$ , stage 1: 5.8-9.0  $\mu\text{m}$ ,  
411 [stage 2: 4.7-5.8  \$\mu\text{m}\$ , stage 3: 3.3-4.7  \$\mu\text{m}\$ , stage 4: 2.1-3.3  \$\mu\text{m}\$ , stage 5: 1.1-2.2  \$\mu\text{m}\$ , stage 6: 0.65-](#)  
412 [1.1  \$\mu\text{m}\$ , stage 7: 0.43-0.65  \$\mu\text{m}\$ \). Quartz filters were extracted and analyzed following the same  
413 procedure as the Teflon filters discussed above, with the addition of a syringe filtration step to  
414 remove insoluble fibers. The cascade impactor was positioned on the roof of the trailer and  
415 pulled 28.3 L/min \(\[GAST 1531-107B-G557X pump\]\(#\)\) through the inlet for periods of 8 hours  
416 during the day and at night \(same timing as above\).](#)

417 Finally, we computed 48-hour backward trajectories for every hour during each offline  
418 sample collection period with the HYSPLIT Backward Trajectory Model (accessed online at  
419 <https://www.ready.noaa.gov/HYSPLIT.php>), using GDAS1.0 meteorological data, the field site's  
420 coordinates as each trajectory's end point, and a final trajectory height of 50 m above the  
421 ground. [We selected 48 hours trajectories to focus on regional influence at the site, and we](#)  
422 [selected a final height of 50 m to be high enough to focus on the overall 48-hour dynamics and](#)  
423 [reduce the possible influence of surface topography. Contributions from air parcels extending](#)  
424 [beyond 48 hours likely exist, but are outside of the regional scope of our study.](#)

425

426 **Figure 1.** (A) Simplified analytical system setup for functionalized gas-phase compounds,  
 427 showing (i) desorption from the PEEK collector and trapping on the LC column in order to focus  
 428 analytes prior to chromatographic separation, and (ii) subsequent chromatographic separation  
 429 and analysis (discussed in detail in Section S1). Green shading indicates active solvent flow  
 430 through PEEK collector and/or LC column. A multi-position valve was switched from position  
 431 “a” (panel (A)i)) to position “b” (panel (A)ii)) to remove the PEEK collector from the flow path  
 432 for chromatography and analysis. Table S1 describes the flow rates and solvents used in each of  
 433 these steps. (B) Comparison of select peaks from a typical LC run (solid traces from 10-23 min)  
 434 to that from a PEEK collector spiked with a standard (bold traces from 30-43 min) demonstrates  
 435 desorption, trapping/focusing, and similar chromatography. Comparable results from a 2-hour  
 436 breakthrough test at 2°C with 22 mL/min air flow are also shown (overlaid dotted traces from  
 437 30-43 min). Spiked PEEK and breakthrough tests were performed to validate this sampling and  
 438 analysis methods, and are discussed further in Section S1. Test analytes were used across a range  
 439 of functionality, with examples shown here and the full list in Table S2.

440 **3. Results and Discussion**

441 3.1. Characteristics of the Urban Regional Site

442 Backward trajectories for summertime and wintertime samples showed a strong urban  
443 influence. Summertime trajectories ranged from the northwest, west, and especially the  
444 southwest (i.e., New York City and other coastal metropolitan areas, similar to well-established  
445 and expected air flow patterns near the Long Island Sound). In contrast, trajectories were almost  
446 exclusively from the northwest in the winter (Figure S1). These air parcels brought a range of  
447 compounds from a mixture of anthropogenic, biogenic, and marine sources to the site, all with  
448 differences in gas- and particle-phase source profiles. However, due to the varied backward  
449 trajectories, dynamic variations in wind direction over the long duration filter samples (Figure  
450 S2), and a high degree of mixing over the Sound, our 8-hour samples are representative of mixed  
451 regional conditions in summer and winter, and are thus discussed in this context. Further detailed  
452 site characterization can be found in Section S2 and Figures S1-S3.

453

454 3.2. ~~Summer and Winter~~ Comparisons of Functionalized Organic Aerosols

Deleted: Seasonal

455 3.2.1. *Summertime composition and the influence of photochemistry and NO<sub>x</sub>*

456 During this period of active photochemistry, the observed distribution of particle-phase  
457 compounds in summertime samples spanned across the intermediate volatility (IVOC) to  
458 ultralow volatility organic compound (ULVOC) range, with a predominance of semivolatile  
459 (SVOC), low volatility (LVOC), ~~and~~ extremely low volatility organic compounds (ELVOC) ~~as~~  
460 ~~shown in Figure 2A as a function of compound class. To assess differences in summer and~~  
461 ~~winter volatility distributions, we used individual molecular formulas and the Li et al. (2016)~~  
462 ~~parameterization to estimate the saturation mass concentration (log(C<sub>0</sub>)) of each observed~~

Deleted: and

465 [compound](#) (Li et al., 2016). [Compounds were then classified into volatility bins following these](#)  
466 [definitions: VOC > 3\\*10<sup>6</sup> µg/m<sup>3</sup>; 3\\*10<sup>6</sup> µg/m<sup>3</sup> > IVOC > 300 µg/m<sup>3</sup>; 300 µg/m<sup>3</sup> > SVOC > 0.3](#)  
467 [µg/m<sup>3</sup>; 0.3 µg/m<sup>3</sup> > LVOC > 3\\*10<sup>-5</sup> µg/m<sup>3</sup>; 3\\*10<sup>-5</sup> µg/m<sup>3</sup> > ELVOC > 3\\*10<sup>-9</sup> µg/m<sup>3</sup>; 3\\*10<sup>-9</sup>](#)  
468 [µg/m<sup>3</sup> > ULVOC](#) (Donahue et al., 2011; Schervish and Donahue, 2020).

469 Due to elevated summertime O<sub>3</sub> mixing ratios at the site (shown in Figure S3, 8-hour  
470 maximum mixing ratio in summer: 57 ± 20 ppb, vs. winter: 46 ± 5 ppb, including day and night  
471 sampling periods), O<sub>3</sub> may have influenced the photochemical processing of emitted volatile  
472 species, especially unsaturated biogenic VOCs which readily undergo ozonolysis due to their  
473 chemical structure. However, we did not observe a correlation between 8-hour maximum (or 8-  
474 hour average) O<sub>3</sub> mixing ratios with average particle-phase volatility ([as saturation mass](#)  
475 [concentration](#)), carbon number, or O/C (nor did we observe such relationships for gas-phase  
476 organic compounds). There were, however, weak relationships between NO<sub>x</sub> mixing ratios and  
477 each of these particle-phase characteristics in the summer. While average NO<sub>x</sub> mixing ratios  
478 were slightly lower during the summer (as shown in Figure S3, 2.3 ± 1.5 ppb in summer vs. 3.7 ±  
479 2.7 ppb in winter), NO<sub>x</sub> mixing ratios trended weakly with particle-phase O/C (r ~ 0.45),  
480 volatility (as saturation mass concentration, r ~ 0.49), and inversely with carbon number (r ~ -  
481 0.56) in summer.

482 While our correlations and conclusions are somewhat limited by the 8-hour filter  
483 sampling duration and the resulting highly regionally-mixed samples, one possible hypothesis is  
484 that the presence of NO<sub>x</sub> could have promoted more fragmentation reactions in the gas-phase  
485 (Loza et al., 2014) that decreased average carbon number, and correspondingly increased  
486 volatility and O/C. In fact, we observed highly oxidized C<sub>3</sub>-C<sub>6</sub> compounds in the gas-phase (from  
487 adsorbent tube measurements with GC-APCI (Section S2)) that were possibly products of these

Deleted: 2

Deleted: , p < 0.05,

Deleted: S2

Deleted: , p < 0.05

Deleted: log(C<sub>0</sub>),

493 fragmentation reactions of larger compounds. These trends of NO<sub>x</sub> mixing ratios with O/C,  
494 volatility, and carbon number were not apparent for the observed complex mixture of gas-phase  
495 organic compounds. However, these highly oxidized gases may not have persisted in the gas-  
496 phase and could have been taken up by the condensed/aqueous phase due to their water  
497 solubility, where they would have instead contributed to the observed trends of NO<sub>x</sub> with carbon  
498 number, volatility, and O/C in the particle-phase. We note that if there was significant uptake of  
499 gas-phase NO<sub>z</sub> to the particle-phase, this may have in part contributed to the particle-phase  
500 correlations with NO<sub>x</sub> given that the chemiluminescence NO<sub>x</sub> analyzer used in this study is  
501 known to also respond to gas-phase NO<sub>z</sub> (Dunlea et al., 2007).

502 Additionally, NO<sub>x</sub> could have been involved in heterogeneous chemistry, promoting  
503 oxidation and/or nitrogen addition reactions, such as interaction with NO<sub>3</sub><sup>\*</sup> to yield organonitrates  
504 (Lim et al., 2016), formation and interaction with HONO to yield nitrophenols (Vidović et al.,  
505 2018), or other pathways.

506

### 507 3.2.2. Comparison to wintertime composition and the role of aqueous-phase chemistry

508 In the winter, these same relationships between NO<sub>x</sub> and particle-phase characteristics  
509 were not observed. This is possibly due to the decreased role of photochemistry in the winter and  
510 the increased role of other competing physical and chemical processes, such as aqueous-phase  
511 chemistry. [In the discussion of our results, we note that aqueous-phase chemistry is meant to be  
512 inclusive of aqueous processing in aerosols, in cloud water, and/or in fog water, all of which may  
513 have occurred upwind of the site during the 8 hour sampling periods under variable local and  
514 regional weather conditions.](#)

Deleted: with variations in weather conditions

516 In the winter, we observed a generally higher average saturation mass concentration  
 517 (summer:  $\log(C_0) = -3.7 \pm 3.9 \mu\text{g}/\text{m}^3$ , vs. winter:  $\log(C_0) = -0.7 \pm 4.0 \mu\text{g}/\text{m}^3$ ). We note that this  
 518 comparison of saturation mass concentrations was performed at a reference temperature of 300  
 519 K, and we discuss the expected wintertime volatility shift below. The wintertime O/C was also  
 520 slightly lower than summer (summer:  $O/C = 0.5 \pm 0.4$  vs. winter:  $O/C = 0.4 \pm 0.4$ ). In the winter,  
 521 the observed chemical composition of the particle phase—both in terms of volatility and  
 522 functional group distribution—suggests a relatively greater role for aqueous-phase processing.  
 523 Our observations were similar to those made in past studies of higher volatility products from  
 524 fragmentation reactions in the aqueous phase (e.g., Brege et al., where they observed that aged  
 525 fog-water samples contained organic compounds with smaller carbon backbone structures than  
 526 non-aqueous aged particles, and linked this difference to aqueous-phase fragmentation reactions,  
 527 the uptake of smaller water-soluble gases to the aqueous-phase, and/or less oligomerization  
 528 (Brege et al., 2018); Yu et al., which discussed the role of fragmentation in aging aqueous  
 529 phenolic secondary organic aerosol (Yu et al., 2016); and Schurman et al., which discussed the  
 530 role of fragmentation and evaporation in cloud water (Schurman et al., 2018)). Similarly, here we  
 531 observed a shifted compound distribution that included smaller molecular weight and generally  
 532 higher volatility particle-phase species in winter compared to summer, along with notably  
 533 different functional group distribution, both of which could be attributed to aqueous chemistry.  
 534 We note that for direct comparison, volatility bins in Figure 2A-B were defined for the  
 535 same reference temperature (i.e., 300 K, the average summertime sampling period temperature),  
 536 though wintertime saturation mass concentrations for the observed compounds would shift  
 537 approximately 2 orders of magnitude lower due to lower temperatures (i.e., 270 K). The dotted  
 538 black line in Figure 2B shows the shift in bins expected at 270 K. In the winter, compounds

**Formatted:** Font color: Text 1

**Formatted:** Indent: First line: 0.5"

**Deleted:** In contrast, there was a larger proportion of LVOCs, ELVOCs, and ULVOCs in summer, which decreased the average summertime volatility of the functionalized organic aerosol components. This was likely driven by increased photochemical processing in summer, leading to lower saturation mass concentrations (summer:  $\log(C_0) = -. \pm . \mu\text{g}/\text{m}^3$ , vs. winter:  $\log(C_0) = -. \pm 4. \mu\text{g}/\text{m}^3$ ,  $p < 0.05$ ) and higher O/C (summer:  $O/C = 0.5 \pm 0.4$  vs. winter:  $O/C = 0.4 \pm 0.4$ ,  $p < 0.05$ ).

565 [defined IVOCs or SVOCs at 300 K will expectedly exhibit a greater degree of partitioning to the](#)  
566 [particle phase, though the effect of this temperature shift on partitioning was likely more](#)  
567 [pronounced for the SVOCs than IVOCs \(Table S4\). Even when accounting for this shift, the](#)  
568 [mean saturation mass concentration of wintertime samples was  \$\log\(C\_0\) = -2.7 \pm 3.9 \mu\text{g}/\text{m}^3\$ ,](#)  
569 [which is still higher than the mean summertime saturation mass concentration of  \$\log\(C\_0\) = 3.7 \pm\$](#)   
570 [3.9  \$\mu\text{g}/\text{m}^3\$  and thus still demonstrates a volatility difference between summer and winter, with](#)  
571 [higher volatility species in winter. This shift is also reflected in the carbon number distribution](#)  
572 [observed via the LC-ESI-MS/MS analysis of this sample set shown in Ditto et al., \(2020\), Figure](#)  
573 [S5. In addition to this shift in molecular size and volatility, there was a distinct change functional](#)  
574 [group composition from summer to winter, discussed below.](#)

575 To assess the potential contribution of aqueous-phase chemistry, we also estimated  
576 aerosol liquid water concentrations based on available data in Section S2.1. [We estimated a](#)  
577 [lower but still appreciable aerosol liquid water content in winter relative to summer, but with](#)  
578 [fewer photochemical processes in winter along with generally cloudier/foggier local weather](#)  
579 [\(i.e., 44% of summer sampling periods with partly cloudy or cloudy weather conditions vs. 67%](#)  
580 [of winter sampling periods, from Weather Underground archive\), aqueous-phase processing](#)  
581 [likely remains an important pathway. We note that the compounds discussed here could have](#)  
582 [been formed locally or regionally, and thus the role of conditions at the site \(aerosol liquid water,](#)  
583 [cloud cover, fog cover\) is just as important as the conditions in the surrounding upwind region.](#)  
584 [As a result, it is challenging to pinpoint the exact contributions of aerosol liquid water, in-cloud,](#)  
585 [or in-fog processing, and we consider that all three may be occurring upwind or near the site.](#)

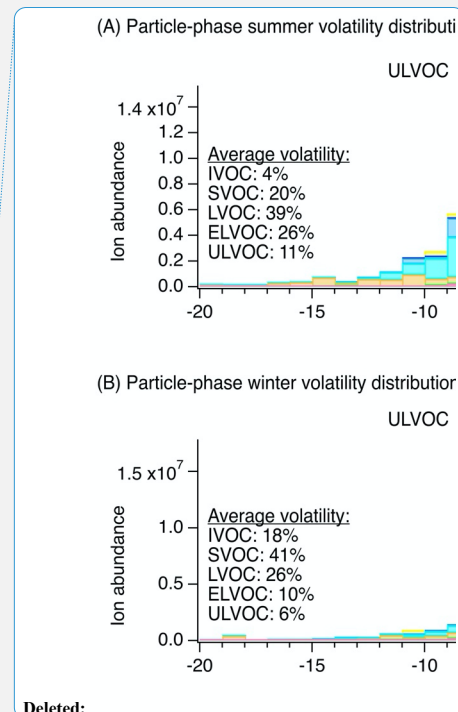

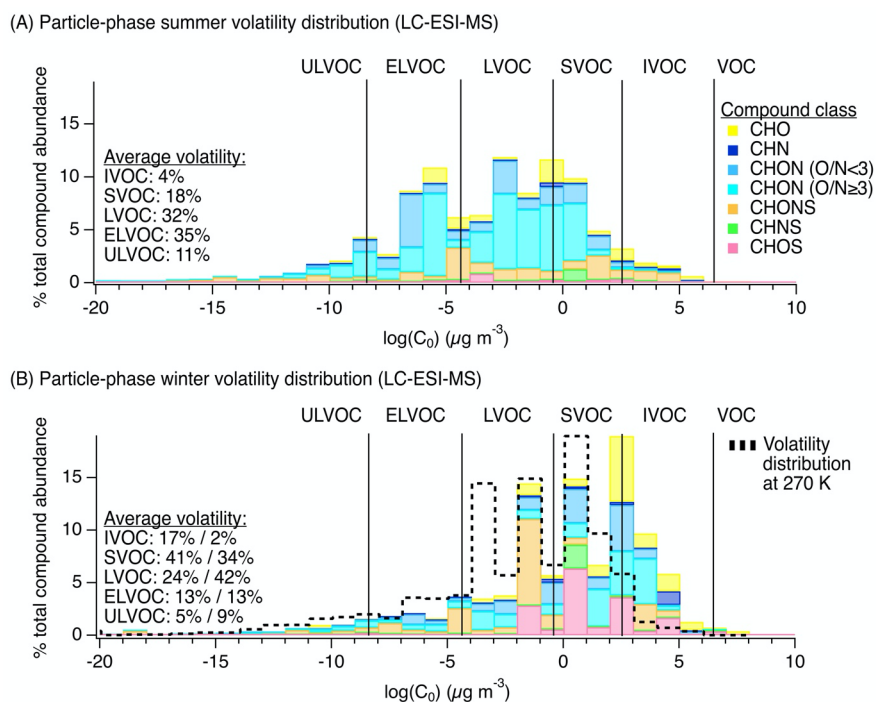

586 Furthermore, from MS/MS analysis, we observed functional groups that were possible  
587 indicators of aqueous-phase processing, including the presence of nitrophenols during the winter,

588 which may have formed via dark aqueous-phase reactions with HONO (Vidović et al., 2018),  
589 and relatively low contributions from carbonyls across seasons, possibly linked to carbonyl  
590 hydrolysis (Ditto et al., 2020). Based on laboratory studies, the presence of azole functional  
591 groups and other heterocyclic nitrogen species could also indicate aqueous phase processing, and  
592 may be formed from small carbonyl precursors such as glyoxal (DeHaan et al., 2009; Grace et  
593 al., 2019) and biacetyl (Grace et al., 2020) reacting with atmospheric ammonia or small amines.  
594 Many of the N-only containing azoles observed here had similar substructures to those formed in  
595 the aqueous-phase reactions of small carbonyls with ammonia/amines (DeHaan et al., 2009;  
596 Grace et al., 2019). In addition, as discussed above, we observed many small gas-phase C<sub>3</sub>-C<sub>6</sub>  
597 compounds at the site in the summer, which likely included multifunctional isoprene oxidation  
598 products (e.g., glycoaldehyde, hydroxyacetone, and isomers); these potential precursors could  
599 have reacted with atmospheric ammonia or species containing amino groups to form the  
600 observed azole-containing reaction products. We observed more azoles during the summer (Ditto  
601 et al., 2020), perhaps due to the increased prevalence of the C<sub>3</sub>-C<sub>6</sub> precursors and overall  
602 prominence of [atmospheric water \(e.g., aerosol liquid water, cloud water, fog water\)](#).

Deleted: aerosol liquid

603       Lastly, the role of aqueous-phase chemistry in the region is further supported by prior  
604 summertime observations at Brookhaven National Laboratory (on the opposite side of the Long  
605 Island Sound), which examined a low-volatility oxygenated organic aerosol factor in the source  
606 apportionment of aerosol mass spectrometry measurements, and showed a strong contribution  
607 from carboxylic acids and other ELVOCs that were attributed to aqueous-phase processing  
608 (Zhou et al., 2016).

Deleted: Compound volatility was estimated and grouped following approaches in the literature (Li et al., 2016; Schervish and Donahue, 2020).

Deleted: Thus, in the winter, a larger fraction of I/SVOCs would have partitioned to the particle phase, though this effect was likely more pronounced for SVOCs than IVOCs (see Table S4).

610

611 **Figure 2.** Chemical composition of particle-phase organic compound mixtures at the YCFS from  
 612 LC-ESI-MS measurements. (A) and (B) show particle-phase volatility distributions by  
 613 compound class in the summer (N=34) and winter (N=15), respectively, [weighted by ion](#)  
 614 [abundance](#). [The same data tallied by occurrence are shown in Figure S4 for comparison.](#) For  
 615 direct comparison, volatility bins were defined for the same reference temperature in (A) and (B)  
 616 (i.e., 300 K, the average summertime sampling period temperature), though wintertime saturation  
 617 mass concentrations for the observed compounds would shift approximately 2 orders of  
 618 magnitude lower due to lower temperatures (i.e., 270K). [The dotted black line in \(B\) shows the](#)  
 619 [shift in bins expected at 270 K, described further in Table S4.](#) The average volatility distributions  
 620 listed in (B) are shown at 300 K (%) followed by the estimate at 270 K (%).

621  
 622 [3.2.3. Comparison to other sites using the same sampling and analytical methods](#)

623 The distribution of compound classes observed at the YCFS was significantly different  
 624 from observations at a range of field sites discussed in past studies (Figure 3), including a remote  
 625 forested site (i.e., the PROPHET site in Northern Michigan), an urban inland site (i.e., near

634 downtown Atlanta) across two seasons, and in New York City (Ditto et al., 2018, 2019). [We](#)  
635 [perform a direct comparison to our past studies here, because the same sampling and analytical](#)  
636 [methods were used, thus we can compare the distribution of ions observed without any biases](#)  
637 [due to differences and uncertainties resulting from variations in sampling or ionization chemistry](#)  
638 [between instruments.](#) While a [more](#) detailed site-to-site comparison is outside the scope of this  
639 work, the proximity of the YCFS to the ocean and thus the impact of marine emissions and over-  
640 water chemistry likely contributed to the differences between the YCFS and inland locations. In  
641 particular, at the YCFS, we observed notably smaller relative contributions from compounds  
642 containing carbon, hydrogen, and oxygen (i.e., CHO, 11-16% of observed functionalized  
643 compounds here vs. 34-50% at other sites), and the contributions from nitrogen-containing  
644 particle-phase compounds at the YCFS were in stark contrast to other sites. Here, 85% of  
645 compounds (by ion abundance) in summer and 68% of compounds in winter contained at least  
646 one nitrogen atom, compared to 38-51% at the other previously studied sites (Figure 3). These  
647 nitrogen-containing species were comprised of compounds with various reduced and oxidized  
648 nitrogen-containing functional groups with varying oxygen-to-nitrogen ratios (O/N), which are  
649 broadly classified and discussed below as compounds containing carbon, hydrogen, and nitrogen  
650 (i.e., CHN), and compounds containing carbon, hydrogen, oxygen, and nitrogen (i.e., CHON  
651 (O/N ratio < 3), and CHON (O/N ratio ≥ 3)). There were notably greater contributions at the site  
652 from nitrogen-containing compounds that also contained at least one oxygen atom, including  
653 CHON compounds with O/N < 3 (19-20% here vs. 10-15% at other sites), CHON compounds  
654 with O/N ≥ 3 (24-44% here vs. 14-19% at other sites), as well as compounds containing oxygen,  
655 nitrogen, and sulfur (i.e., CHONS, 20-21% here vs. 9-10% at other sites) (Ditto et al., 2018).

**Deleted:** See Section S3 and Figure S4 for discussion of additional compound classes.

658 We note that while these [measurements were of PM<sub>10</sub> aerosols](#), the observations of high  
659 nitrogen content were not biased by the inclusion of larger, [primary \(possibly biological\)](#)  
660 particles. Quartz filter samples collected with a cascade impactor at the site during the summer  
661 and analyzed with the same LC-ESI-MS methods did not show any [significant differences](#)  
662 between any of these nitrogen-containing compound classes as a function of particle size, across  
663 particles ranging from 0.4 to 10  $\mu\text{m}$  [\(i.e., 69%-71% of ion abundance for PM  \$\leq\$  2.2  \$\mu\text{m}\$  and 69%-](#)  
664 [73% of ion abundance for PM ranging from 2.2-10  \$\mu\text{m}\$  were nitrogen-containing species,](#)  
665 [summarized in Table S5\)](#). This is consistent with past studies which have demonstrated that  
666 amines, [as one example of a prominent nitrogen-containing functional group](#), are ubiquitous in  
667 size-resolved aerosol samples in urban and rural locations (VandenBoer et al., 2011).

668 The prevalence of nitrogen-containing species at the YCFS is consistent with the study at  
669 Brookhaven National Laboratory discussed above, where a dedicated nitrogen-enriched aerosol  
670 mass spectrometry factor was identified, and contained prevalent signal from aliphatic amines  
671 and amides. However, in the Brookhaven study, the nitrogen-enriched factor was associated with  
672 industrial amine emissions that were enhanced during periods of south/southwestern backward  
673 trajectory influence, and that had correlations with tracers linked to industrial processes. In our  
674 study, there was no correlation between backward trajectory direction and the contribution of  
675 nitrogen-containing species. Also, wintertime air parcels arrived predominantly from directions  
676 other than south/southwest, suggesting that the nitrogen-containing species observed in our study  
677 were the result of mixed anthropogenic, biogenic, and marine precursors and their transformation  
678 products. [This high nitrogen content at the YCFS, where aqueous-phase chemistry is expected to](#)  
679 [be important, is also consistent with the cloud water composition discussed in Zhao et al. \(2013\),](#)  
680 [which reported roughly 65% of detected ions in their cloud water samples to contain a nitrogen](#)

687 [atom, and the primary marine aerosol composition discussed in Wozniak et al. \(2014\), where](#)  
 688 [61% of their observed compounds contained nitrogen and 54% were CHON species.](#)

689 **Figure 3.** Particle-phase compound class distributions shown as fractions of total detected ion  
 690 signal in the (A) summer and (B) winter at the YCFS, weighted by compound abundance, in  
 691 contrast with (C) the average compound class distribution from previously studied forested,  
 692 urban inland, and urban coastal sites. The sites selected for comparison in (C) were chosen  
 693 because the same sampling and analysis methods were used. Nitrogen-containing compound  
 694 class contributions are outlined in black, and are notably larger at the coastal site compared to  
 695 other sites studied with these same filter collection and analysis methods. We note that while a  
 696 significant fraction of species contained nitrogen, individual compounds contained 1-3 nitrogen  
 697 atoms and the majority of the ion's molecular mass consisted of carbon and hydrogen atoms  
 698 (mean N/C in summer: 0.13±0.1, mean N/C in winter: 0.22±0.19 for all N-containing ions).  
 699 Note: CH and CHS species have poor ESI ionization efficiencies and are thus excluded here.  
 700 Data tallied by occurrence are shown in Figure S5 for comparison.

**Deleted:** (A)

**Deleted:** (B)

**Deleted:** (C).

708 3.3. Speciating Particle-Phase Multifunctional Nitrogen-Containing Compounds

709 The observed particle-phase species were highly functionalized, often multi-functional,  
710 and contained combinations of oxygen, nitrogen, and/or sulfur heteroatoms. Here, we discuss the  
711 functional groups present, broken up by the nitrogen-containing compound classes shown in  
712 Figures 2-3, with additional discussion of other relevant compound classes in Section S3.

714 3.3.1. CHN compounds

715 While nitrogen-containing compounds in general were very prominent at the site (Figure  
716 3A-B), CHN compounds were relatively less abundant in these samples of functionalized  
717 organic aerosol. Particle-phase CHN compounds represented just 1% and 3% of observed  
718 functionalized organic aerosol abundance in summer and winter, respectively, which was similar  
719 to observations at other ambient sites (~5% CHN) (Ditto et al., 2018).

720 In the summertime LC-ESI-MS/MS measurements, CHN particle-phase compounds were  
721 comprised primarily of amines (72% of CHN species contained an amine group) and nitriles  
722 (28% of CHN species contained a nitrile group), as shown in Figure 4. In the winter, these  
723 compounds were nearly exclusively amines (present in 99% of CHN species). Amines have  
724 many primary land-based sources (e.g., biogenic emissions (Kieloaho et al., 2013), agricultural  
725 activity (Ge et al., 2011), emissions from decomposing organic matter (Ge et al., 2011;  
726 Sintermann and Neftel, 2015), biomass burning (Ge et al., 2011), emissions from port activity  
727 (Gaston et al., 2013), chemical products (Khare and Gentner, 2018), and vehicle exhaust  
728 (Sodeman et al., 2005)), but their presence on the coast could also indicate marine contributions.  
729 Amines have been detected both in bulk ocean water, the surface microlayer, and in sea spray  
730 aerosol, and their emissions and chemical transformations in the marine environment have been

731 the topic of many recent studies (e.g., Brean et al., 2021; Dall'Osto et al., 2019; Decesari et al.,  
732 2020; Di Lorenzo et al., 2018; van Pinxteren et al., 2012, 2019; Quinn et al., 2015; Wu et al.,  
733 2020). [In the summer, biogenic and marine sources likely dominated the amine distribution,](#)  
734 [while in the winter, anthropogenic amine sources likely became more important.](#)

735 Recent studies have also evaluated amine phase partitioning or formation in cloud/fog  
736 water (e.g., Chen et al., 2018; Youn et al., 2015), as well as condensed-phase or aqueous-phase  
737 pathways that may transform emitted amines (e.g., Ge et al., 2016; Lim et al., 2019; Tao et al.,  
738 2021). Interestingly, the observed amines at this site, as well as other reduced nitrogen groups  
739 like nitriles, imines, and enamines, were not present exclusively in CHN species and thus were a  
740 mix of both direct emissions and chemically processed compounds. Reduced nitrogen groups  
741 were often paired with hydroxyl groups, carboxylic acids, carbonyls, ethers, and esters as part of  
742 nitrogen and oxygen containing compounds with a range of O/N ratios. [This is consistent with](#)  
743 [other studies observing reduced-nitrogen contributions to CHON compound classes, such as](#)  
744 [Zhao et al. \(2013\), LeClair et al. \(2012\), and Altieri et al \(2009\), discussed above.](#) As such, we  
745 discuss CHON species as a function of O/N ratio to focus on differences between less-  
746 oxygenated ( $O/N < 3$ ) and more-oxygenated ( $O/N \geq 3$ , e.g., organonitrates) species, using a ratio  
747 of 3 to distinguish between the two as informed by the O/N ratio of the organonitrate functional  
748 group.

#### 749 3.3.2. CHON ( $O/N < 3$ ) compounds

751 CHON ( $O/N < 3$ ) compounds were notably more important at this site than other sites,  
752 representing 20% and 19% of observed functionalized organic aerosol abundance in summer and  
753 winter, respectively (Figure 3A-B), compared to ~13% at other sites (from predominantly

754 summer measurements). These CHON compounds included some functional groups that  
755 contained both oxygen and nitrogen, such as amide groups (12% of this compound class's  
756 nitrogen content in summer, vs. 1% in winter, Figure 4) and nitro groups (15% of this nitrogen  
757 content in summer, vs. 6% in winter, Figure 4). However, most CHON (O/N < 3) compounds  
758 were comprised of a combination of nitrogen- *or* oxygen-containing groups, rather than a  
759 functional group containing both nitrogen and oxygen. This included large contributions from  
760 hydroxyls and ethers across both seasons, as well as important contributions from amines,  
761 isocyanates, and heterocyclic nitrogen, [as shown in Ditto et al., 2020 \(Figure 1\)](#). The presence of  
762 these functional groups in the winter could be indicative of wood burning emissions in the  
763 region, which has been observed in the wintertime in past ambient sampling in the Northeast  
764 U.S. (Sullivan et al., 2019). Isocyanates contributed notably to this compound class during the  
765 winter, which could similarly be linked to burning wood, other biomass, building materials  
766 (Leslie et al., 2019; Priestley et al., 2018; Roberts et al., 2014), or could be photochemically  
767 produced via the oxidation of amines and amides (Borduas et al., 2015; Leslie et al., 2019).  
768 Importantly, levoglucosan, a common biomass burning tracer, was observed across nearly all  
769 daytime and nighttime winter particle-phase samples (verified with an authentic standard),  
770 supporting the influence of biomass burning compounds at the site. Together, the overall high  
771 prevalence of reduced nitrogen at this site could be influenced by the mixing of aged biomass  
772 burning plumes with marine air, which is consistent with past observations of very high  
773 alkylamine concentrations in biomass burning particles that mixed with marine air prior to  
774 sampling (Di Lorenzo et al., 2018).

Deleted: (Ditto et al., 2020).

775  
776

778 3.3.3. CHON (O/N ≥ 3) compounds

779 CHON (O/N ≥ 3) compounds were the dominant compound class in the observed  
780 summertime distribution and played an important role in the wintertime distribution as well,  
781 comprising 44% of observed functionalized organic aerosol abundance in summer vs. 24% in  
782 winter (Figure 3A-B). These contributions were far greater than the contributions of CHON (O/N  
783 ≥ 3) species at other sites, which typically ranged from 14-19% (predominantly from  
784 summertime measurement, Figure 3C).

785 Similar to CHON (O/N < 3), we observed some CHON (O/N ≥ 3) compounds with  
786 functional groups containing 3 oxygen atoms and 1 nitrogen atom, e.g., nitrophenols and  
787 organonitrates (Figure 4), but also contributions from nitrogen-only functional groups paired  
788 with oxygen-containing groups. Notably, in the summer, there were important contributions from  
789 amines (47% of this compound class's nitrogen content), imines (19%), organonitrates (10%),  
790 and azoles (16%) (Figure 4). In contrast, in the winter, nitrogen content in the CHON (O/N ≥ 3)  
791 compound class was dominated by I/SVOC nitrophenols, comprising 64% of the CHON (O/N ≥  
792 3) ion abundance.

793 NO<sub>x</sub> mixing ratios were typically low in both summer and winter ( $2.3 \pm 1.5$  ppb in  
794 summer vs.  $3.7 \pm 2.7$  ppb in winter), but were slightly higher during winter. In the winter, CHON  
795 (O/N ≥ 3) compounds showed a weak positive relationship with NO<sub>x</sub> mixing ratios ( $r \sim 0.58$ ) and  
796 a stronger correlation with NO mixing ratios ( $r \sim 0.81$ ). This relationship between CHON (O/N ≥  
797 3) and NO (and NO<sub>x</sub>) suggests that many of these oxidized nitrogen species were products of  
798 NO<sub>x</sub>-related chemistry (i.e., NO<sub>2</sub> compounds). The enhancements in nitrophenols serves as one  
799 example of this, as NO mixing ratios also correlated with the contribution of nitrophenols in the  
800 winter ( $r \sim 0.69$ ).

801 In past work, we discussed nitrophenol nighttime enhancements during winter, and noted  
802 their reported aqueous formation pathways mentioned in prior laboratory studies (Ditto et al.,  
803 2020). Here, we demonstrate that nitrophenols were important contributors to the CHON (O/N  $\geq$   
804 3) compound class, and highlight their role as examples of NO<sub>2</sub> due to their possible formation  
805 via dark aqueous-phase nitration pathways of oxygenated aromatics with ambient nitrous acid  
806 (HONO) (Vidović et al., 2018). While nitrophenols may have other sources (e.g., diesel exhaust),  
807 our observations of a clear nighttime enhancement during the winter suggest that these functional  
808 groups were most likely formed by secondary chemistry related to NO<sub>x</sub> oxidation, as this field  
809 site was removed from major roadways. Our wintertime observations suggest that HONO could  
810 have been derived from local wood burning, and could have reacted away as the smoke plume  
811 aged to form stable products like nitrophenols, similar to HONO transformation chemistry into  
812 other forms of oxidized nitrogen (e.g., particulate nitrates, PANs, organic nitrates) that has  
813 recently been observed in wildfire smoke (Juncosa Calahorrano et al., 2021).

814 Furthermore, the correlation between NO and CHON (O/N  $\geq$  3) could also be influenced  
815 by the daytime formation of organonitrates via reaction with OH<sup>•</sup> and NO (i.e., RO<sub>2</sub><sup>•</sup> + NO)  
816 (Liebmann et al., 2019; Ng et al., 2017; Perring et al., 2013; Takeuchi and Ng, 2018), though  
817 organonitrates contributed to a smaller fraction of CHON (O/N  $\geq$  3) species (i.e., 10% of this  
818 compound class's nitrogen content across seasons).

819

#### 820 3.3.4. Overall contributions of reduced and oxidized nitrogen groups

821 In the summer and winter, contributions from reduced nitrogen groups (e.g., groups  
822 shown in black/grey in Figure 4) rivaled that of oxidized nitrogen groups in CHON compounds  
823 across a range of O/N ratios. In the summer, reduced nitrogen groups contributed to 50% of all

824 detected CHON ( $O/N < 3$ ) compounds by ion abundance, while in the winter they contributed  
825 47% (Figure 4). For CHON compounds with  $O/N \geq 3$ , reduced nitrogen groups contributed to  
826 68% of compound ion abundance in the summer (possibly related to marine influences (Wozniak  
827 et al., 2014)), while in the winter they contributed just 13%. Interestingly, 90% of the dominant  
828 reduced nitrogen functional groups observed (amines and imines) were present in acyclic rather  
829 than cyclic structures, which may have been the result of either direct emissions or formation via  
830 reactions with ammonia or other small amines.

831 In contrast, possible  $NO_x$  products (e.g., groups shown in blue in Figure 4) were present  
832 in 18% and 7% of CHON ( $O/N < 3$ ) compounds in the summer and winter, respectively. For  
833 CHON ( $O/N \geq 3$ ) compounds, they were present in 18% and 86% in the summer and winter,  
834 respectively, with the latter wintertime increase in oxidized N-groups largely driven by the  
835 presence of nitrophenols at night (Ditto et al., 2020). The remaining fraction of nitrogen-  
836 containing groups also contained oxygen, but with a reduced nitrogen atom (e.g., amide,  
837 isocyanate, nitrogen/oxygen-containing azole, shown in brown in Figure 4). We note that  
838 CHONS compounds also represented a sizable fraction of observed organic nitrogen (Figure 3),  
839 and contained a mix of reduced and oxidized functional groups (Section S3 and Figures S7-8).

840 The importance of reduced nitrogen functional groups in CHON compounds highlights  
841 that not all oxygen- and nitrogen-containing species in the CHON ( $O/N \geq 3$ ) compound class  
842 were  $NO_x$ , despite their apparent molecular formulas and the observed correlation observed  
843 between CHON ( $O/N \geq 3$ ) species with NO and  $NO_x$  mixing ratios. For instance, many of the  
844 observed reduced nitrogen-containing functional groups co-occurred with several oxygen-  
845 containing groups like hydroxyls, carboxylic acids, esters, ethers, and carbonyls, and thus had

Deleted:

Deleted: 4

848 molecular formulas with  $O/N \geq 3$ , which could incorrectly be assumed to be an organonitrate or  
849 similar structure based on molecular formula alone.

850 We note that the relative distribution of reduced and oxidized nitrogen-containing groups  
851 shown here is subject to sampling and ionization conditions. While the electrospray ionization  
852 source used for the particle-phase analysis discussed here effectively ionized these nitrogen-  
853 containing groups, their relative sensitivity may differ because many of these functional groups  
854 were present in multifunctional compounds whose other features may also contribute to  
855 ionization behavior. Also, other aspects of the sample collection and extraction process could  
856 cause variability in observed signal (e.g., PM size cut, organonitrate stability over long duration  
857 samples). Thus, we emphasize that the observed relative abundances here are valuable because  
858 they suggest that fully reduced nitrogen-containing groups are important contributors to  
859 multifunctional CHON species, but their exact mass contributions remain uncertain.

860

861 **Figure 4.** The distribution of functional groups in particle-phase nitrogen-containing compounds  
 862 measured via LC-ESI-MS/MS. The breakdown of CHN, CHON (O/N < 3), and CHON (O/N ≥  
 863 3) compounds is shown as a function of contributions of each functional group to ion abundance,  
 864 with possible NO<sub>2</sub> species shown in blue shades, fully-reduced nitrogen-containing groups  
 865 shown in black/grey shades, and groups containing both oxygen and nitrogen where the nitrogen  
 866 atom itself is not oxidized shown in brown shades. [The same data tallied by occurrence are](#)  
 867 [shown in Figure S6 for comparison. Figures S7 and S8 show the functional group distribution for](#)  
 868 [CHNS and CHONS compound classes tallied by abundance and by occurrence, respectively.](#)

869

870

871 3.4. Probing Possible Nitrogen-Containing Gas-Phase Precursors to Observed Nitrogen-

872 Containing Particles with Adsorptive Sampling and LC-ESI-MS

873 The particle-phase volatility distribution in the winter [ranged from IVOC-ULVOC](#). Of

874 the observed compounds in winter, 68% contained nitrogen; these likely included contributions

875 from functionalized gas-phase precursors and likely were influenced by the active multiphase

876 partitioning of these precursors, and their gas- or particle-phase reaction products, with changes

Deleted: consisted of 18% IVOCs and 41% SVOCs (Figure 2B)...

879 in organic aerosol loading, atmospheric liquid water concentrations, and temperature (Donahue  
880 et al., 2011; Ervens et al., 2011). This emphasizes the need to measure a broader range of these  
881 functionalized gas-phase compounds, which have known limitations with GC transmission, but  
882 represent uncertain and important-to-measure SOA precursors.

883 However, despite evidence of [higher volatility particle-phase compounds with](#) diverse  
884 nitrogen-containing functionalities that could dynamically partition between phases (Figure 2A-  
885 B), the observed compound class distribution from gas-phase adsorbent tube measurements  
886 analyzed via GC-APCI-MS was dominated by hydrocarbons (i.e., CH, 24% of detected ion  
887 abundance in summer vs. 18% in winter) and oxygenates (i.e., CHO, 66% in summer vs. 69% in  
888 winter) (Figure [S10-11](#)). These gas-phase species appeared to be lightly functionalized  
889 oxygenates (average O/C:  $0.12 \pm 0.13$ ), showing minimal contributions from nitrogen (or sulfur)  
890 heteroatoms; only 9% of detected ion abundance from gas-phase adsorbent tubes in summer and  
891 11% in winter contained a nitrogen heteroatom. This is likely due to measurement limitations;  
892 while GC-APCI techniques are extremely well-suited for the analysis of less functionalized  
893 organic compounds from both instrument transmission and ionization efficiency perspectives,  
894 these techniques are not as effective for more polar, more functionalized, more thermally-labile,  
895 or otherwise less-GC-amenable species. Thus, to examine a broader range of functionalized gas-  
896 phase compounds, we used an offline adsorptive sampling method on cooled PEEK tubing  
897 collectors and inline mobile phase desorption for LC-ESI-MS analysis (Figure 1). CH and CHS  
898 compound classes were excluded from this gas-phase LC-ESI-MS analysis due to their poor ESI  
899 ionization efficiency.

900 Due to variations in trapping and desorption effectiveness (Section S1), this method was  
901 not intended to be used as a quantitative measurement of concentration, but rather a relative

Deleted: substantial contributions from particle-phase I/SVOCs with

Deleted: S5

905 assessment of the distribution of nitrogen-containing gas-phase organic compounds. The  
906 variation between analytes in breakthrough testing does not influence our conclusions about the  
907 overall prevalence of observed gas-phase organic nitrogen. In laboratory tests, gas-phase sample  
908 collection, inline desorption to the mobile phase, trapping on the LC column, and  
909 chromatographic separation performed well. We observed limited breakthrough for most  
910 analytes during sampling, effective focusing prior to LC analysis, and similar separations for  
911 spiked collectors and breakthrough tests compared to standard LC runs (Figure 1B).

912 Results from the application of this new method at the YCFS revealed a wide range of  
913 compounds with oxygen-, nitrogen-, and/or sulfur-containing functionality (Figure 5) that existed  
914 at a lower average saturation mass concentration than the adsorbent tube methods during winter,  
915 with a  $\log(C_0)$  of  $3.5 \pm 3.1 \mu\text{g}/\text{m}^3$  for adsorbent tubes analyzed with GC-APCI-MS compared to  
916  $1.9 \pm 2.1 \mu\text{g}/\text{m}^3$  for functionalized gases observed via LC-ESI-MS. This decrease in volatility  
917 corresponded to an increase in the average O/C ratio of these functionalized gases to  $0.24 \pm 0.24$ ,  
918 which can partly be attributed to LC-ESI's poor ionization of CH compounds and to the  
919 collection system's design (targeting heteroatom-containing species and not higher volatility  
920 hydrocarbons). This may be a lower limit of O/C among functionalized compounds, as during  
921 testing with a mixture of standards, we often observed poor retention of high O/C sugars like  
922 xylitol and mannose on the LC analytical column (Table S2).

923 The gas-phase LC-ESI-MS data provide a valuable comparison to the wintertime  
924 particle-phase samples analyzed using the same instrument. These particle-phase samples had  
925 major contributions from CHO, CHON ( $O/N < 3$  and  $O/N \geq 3$ ), CHONS, and CHOS compound  
926 classes (Figure 3B). While not collected concurrently, the functionalized gas-phase samples in  
927 winter had similar contributions from CHO (20%) and CHON ( $O/N \geq 3$ ) compounds (16%),

928 relatively more CHN (11%) and CHON (O/N < 3) (46%) compounds, and fewer CHONS (2.7%)  
929 and CHOS (4.4%) compounds (Figure 5A). The prevalence of gas-phase CHN, CHON (O/N <  
930 3), and CHON (O/N ≥ 3) is of particular interest given the abundance of CHON compounds  
931 observed in the particle phase, and the potential of these gases to partition to the particle-phase  
932 and/or act as reactive precursors to other oxidized nitrogen-containing species.

933 The presence of these nitrogen-containing compounds in the gas-phase also suggests that  
934 these compound classes observed in the particle-phase at least partly originated in the gas-phase  
935 and partitioned, rather than formed exclusively as a result of particle-phase chemistry. These  
936 species could have also formed in the particle-phase and partitioned to the gas-phase with or  
937 without condensed-phase fragmentation (discussed above). In either scenario, these nitrogen-  
938 containing compounds likely actively partitioned between phases due to their volatility (e.g.,  
939 I/SVOCs shown in Figure 5A). Also, their polarity and high Henry's Law coefficients (relative  
940 to non-functionalized hydrocarbons (Sander, 2015)) suggests that these compounds could have  
941 been readily taken up by the aqueous phase. To check that these compounds were indeed gas-  
942 phase species under ambient conditions, we predicted the saturation mass concentration for  
943 individual compounds using individual ion formulas and estimated their gas-particle partitioning  
944 to a pre-existing condensed phase. While the range of compounds in Figure 5A can be expected  
945 to dynamically partition, the results confirm that the overall suite of observed compounds would  
946 have predominately existed as gases, with on average ~80% of observed ion abundance predicted  
947 to equilibrate to the gas-phase across compound classes (Figure S12-13).

948 Of all the gas-phase species observed with at least one nitrogen atom (i.e., CHN, CHON,  
949 CHONS, CHNS), [collected in winter](#), we note that 78% of these compounds had an O/N ratio of  
950 less than 3 (Figure 5B), indicating that most of these gas-phase species were not organonitrates,

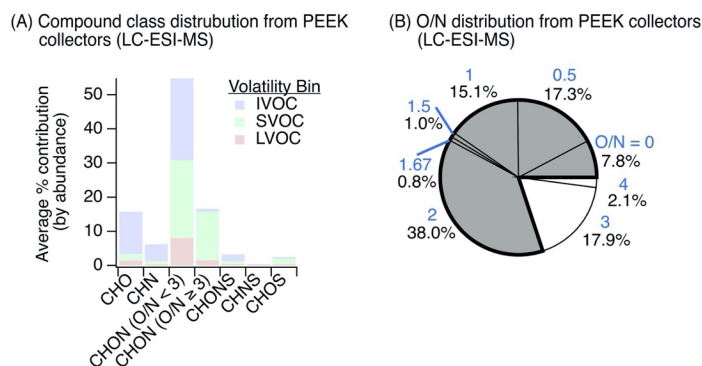

Deleted: 6

952 nitrophenols, or other similar structures. This is similar to our particle-phase [wintertime](#) results,  
953 which showed important contributions from reduced nitrogen-containing groups paired with  
954 oxygen-containing groups in CHON ( $O/N < 3$ ) compounds. Notably, we observed an 11%  
955 contribution of gas-phase CHN species with this gas-phase LC-ESI-MS method (Figure 5A), in  
956 contrast to 2% CHN in the wintertime particle-phase samples (Figure 3). In the winter particle-  
957 phase samples, most CHN compounds contained amines (discussed above), and thus we  
958 postulate that these functionalized gas-phase CHN species were possibly also amines that acted  
959 as precursors to observed nitrogen-containing particle-phase compounds following oxidation and  
960 partitioning (or vice versa).

961         The substantial contribution from CHON with  $O/N < 3$  (46%) to the functionalized gas-  
962 phase samples could be linked to less photochemical processing of CHON compounds relative to  
963 the particle phase and/or the emissions/oxidation of CHN or CHON compounds. Moreover, in  
964 the particle-phase, we observed a weak negative relationship between CHN contribution and  
965 hydroxyl group prevalence in summertime measurements ( $r \sim -0.57$ ), which may support the  
966 transformation of CHN to CHON compounds via the formation of hydroxyl-containing species.

967 [The elemental ratio distribution of these functionalized gases is summarized in Figure S14 and](#)  
968 [Table S6.](#)

969  
 970 **Figure 5.** Observations of gas-phase nitrogen-containing compounds. (A) The distribution of  
 971 functionalized gases observed via sampling on PEEK collectors (N = 6) and inline mobile phase  
 972 desorption with non-targeted LC-ESI-MS analysis contained a diversity of oxygen-, nitrogen-,  
 973 and/or sulfur-containing compounds in the IVOC-LVOC range (volatility assignment and  
 974 grouping was the same as discussed in Figure 2 [at a reference temperature of 300 K for](#)  
 975 [intercomparison](#)). While we cannot rule out gas-phase LVOC contributions from evaporation off  
 976 of the upstream particle filter, LVOC contributions were limited (~12%). (B) Oxygen-to-  
 977 nitrogen (O/N) ratio distribution of observed gas-phase nitrogen-containing species where O/N  
 978 ratios < 3 are colored grey and O/N ratios ≥ 3 are colored white (blue text above each percentage  
 979 signifies the O/N ratio). [The same data, tallied by occurrence, are shown in Figure S9 for](#)  
 980 [comparison](#).

981  
 982 **4. Conclusions and Opportunities for Future Research**

983 Together, these results suggest that a mix of direct emissions and chemical processes  
 984 during summer and winter in the Long Island Sound region resulted in a diverse mixture of  
 985 multifunctional gases and particles, where more than two-thirds of observed particle-phase  
 986 compounds contained at least one nitrogen atom.

987 The observed nitrogen-containing functional groups existed across a range of fully  
 988 reduced (e.g., amines, imines) to oxidized (e.g., nitro, organonitrate) structures. These fully  
 989 reduced nitrogen functional groups were prevalent across all nitrogen-containing compound  
 990 classes, including CHON species, and we highlight their importance as contributors to these  
 991 multifunctional compounds beyond typical NO<sub>x</sub>-type compounds that are commonly studied

992 using online mass spectrometers and share similar CHON molecular formulas. For instance,  
993 these gas- and particle-phase measurements of nitrogen-containing compounds are  
994 complementary to the measurements of these species made by chemical ionization mass  
995 spectrometers (CIMS) or by proton transfer reaction mass spectrometers (PTR-MS), whose  
996 ionization mechanisms can be tuned for sensitivity towards functionalized compounds of interest  
997 (Riva et al., 2019). While online mass spectrometers excel at high time resolution measurements  
998 that capture dynamic chemical processes in the atmosphere, their mass resolution is typically  
999 lower and they normally do not utilize separations, so they largely depend on parent ion mass-to-  
1000 charge ratios to assign molecular formulas without structural attribution. The offline methods  
1001 used here cannot match the time resolution of online techniques. However, the use of  
1002 chromatography to separate isomers, longer sampling times to increase sensitivity toward a  
1003 greater range of compounds, and the use of higher resolution mass spectrometers with MS/MS  
1004 capabilities allow for improved compound identification and determination of functional group  
1005 distribution at the molecular level. This enables us to distinguish between true NO<sub>z</sub> species and  
1006 those that contain combinations of nitrogen and oxygen but are not NO<sub>x</sub> oxidation products.  
1007 Thus, both these online and offline methods should be employed together to differentiate a wider  
1008 range of nitrogen-containing species and to achieve both temporal and chemical resolution.

1009 As discussed throughout this work, the Long Island Sound region is affected by a mixture  
1010 of anthropogenic, biogenic, and marine sources, all of which contain known emitters of organic  
1011 nitrogen. Understanding the combined effect of these individual sources and their chemical  
1012 transformations will be important in regions like the Long Island Sound, where a significant  
1013 degree of mixing occurs over the Sound before air parcels arrive inland. For example, past work  
1014 has noted extremely high contributions from alkylamines in biomass burning-influenced air

1015 mixed with marine air (Di Lorenzo et al., 2018). Similar enhancements could be expected when  
1016 mixing other prominent sources of amines with marine air, such as in the aging urban outflow  
1017 from the Central Atlantic and Northeast U.S., which may be transported up the coast and impact  
1018 states in the surrounding region.

1019 As with any ambient site, these mixed emissions are chemically processed in the  
1020 atmosphere via a multitude of pathways. Here, we observed evidence of photochemical and  
1021 aqueous processes occurring in both seasons, but in the winter we observed various mixture-wide  
1022 trends that suggested an enhanced role for aqueous-phase processing. These observations  
1023 included higher overall particle-phase volatility and smaller carbon backbone sizes, which may  
1024 indicate a more important role for aqueous-phase fragmentation reactions or aqueous uptake of  
1025 water soluble gases (Brege et al., 2018). We also observed key marker functional groups that  
1026 may be formed via aqueous phase chemistry (e.g., nitrophenols, azoles). The role of aqueous-  
1027 phase chemistry and aqueous-phase uptake of gases is increasingly studied in laboratory and  
1028 ambient contexts (Herrmann et al., 2015), and such chemistry should further examined especially  
1029 in coastal and other humid regions.

1030 For example, the aqueous-phase processing of atmospherically relevant nitrogen-  
1031 containing species is particularly important to understand in ambient air due to the potential of  
1032 brown carbon formation, which has significant impacts on climate forcing (Laskin et al., 2015).  
1033 The role of ammonia and amines reacting with carbonyls is of interest for this type of chemistry  
1034 (e.g., DeHaan et al., 2009; Grace et al., 2020; McNeill, 2015; Sareen et al., 2010) and should  
1035 continue to be explored, particularly in coastal settings where concentrations of small gas-phase  
1036 amines may be high due to their marine sources. As discussed above, our ambient observations  
1037 of azoles could be indicative of such chemistry, and should be explored in future comparisons of

1038 ambient and laboratory-generated species. Also, we observed a significant contribution from  
1039 nitrophenols at our site, and while they are not formed by this same chemistry, they represent  
1040 another important form of light absorbing nitrogen-containing organic mass in the atmosphere  
1041 (Hems and Abbatt, 2018). Finally, many of the nitrogen-containing functional groups observed  
1042 in this work may be susceptible to hydrolysis, so the balance between hydrolysis and other  
1043 aqueous pathways is important to consider and understand for appropriate representation of  
1044 nitrogen-containing compounds in models for both aqueous aerosol and in-cloud/fog chemistry.

1045 As another example, the greater prevalence [overall higher volatility species](#) observed in  
1046 the winter particle-phase samples suggested possible dynamic partitioning or aqueous uptake of  
1047 lighter gas-phase compounds; to explore the composition of these lighter gas-phase compounds  
1048 that could exist as I/SVOCs and thus participate in phase partitioning, we supplemented our  
1049 particle-phase analyses with a novel approach for investigating functionalized gases with LC-  
1050 ESI-MS. Further investigation of these nitrogen-containing gases will facilitate new  
1051 understanding of their gas-particle partitioning in the presence of [atmospheric water and organic](#)  
1052 condensed species, and measurements across dynamic conditions will help elucidate the relative  
1053 importance of both processes. For these types of measurements, further design iterations of the  
1054 PEEK sampling system for functionalized gases and additional functionalized gas-phase samples  
1055 for LC-ESI-MS analysis could be pursued. Concurrent high volume filter samples could be  
1056 collected for direct comparison to the particle-phase, which was not possible in this study due to  
1057 insufficient mass loading on the upstream filter during the short duration functionalized gas  
1058 sample (i.e., 2 hours). Concurrent PEEK samples could also be collected for MS/MS analysis.

1059 In all, combinations of online and offline mass spectrometry to obtain temporal and  
1060 chemical detail, further ambient observations of major organic nitrogen sources, a better

Deleted: of I/SVOCs

1063 understanding of the aqueous processing of nitrogen-containing compounds, and improved  
1064 characterization of their gas-particle partitioning in the presence of [atmospheric](#) water will  
1065 together allow for a more accurate representation of nitrogen-containing organic compounds in  
1066 emission inventories and models, and enhance our ability to predict their impacts on atmospheric  
1067 composition, human health, and climate.
