15  
16 **Abstract:** Aqueous reactions may turn precursors into light-absorbing and toxic  
17 products, leading to air quality deterioration and adverse health effects, ~~etc.~~ In this study,  
18 we investigated comprehensively eugenol photooxidation (a representative biomass  
19 burning emitted, highly substituted phenolic compound) in bulk aqueous phase with  
20 direct photolysis, hydroxyl radical (OH) and an organic triplet excited state (<sup>3</sup>C\*  
21 Results show that the degradation rates of eugenol followed the order of  
22 <sup>3</sup>C\* > OH > direct photolysis. ~~Quenching experiments verified that <sup>3</sup>C\* indeed played a~~  
23 ~~dominant role in~~ During <sup>3</sup>C\* -initiated oxidation, while different reactive oxygen  
24 species (ROS) including <sup>3</sup>C\*, OH, <sup>1</sup>O<sub>2</sub> and O<sub>2</sub>\*<sub>g</sub> generated can participate in oxidation of  
25 eugenol, quenching experiments verified <sup>3</sup>C\* was the most important ~~for one; while~~

带格式的: 非上标/下标

带格式的

带格式的: 非上标/下标

26 ~~during~~ OH-initiated oxidation. ~~Photolysis, O<sub>2</sub><sup>\*</sup> was a more important ROS than OH to~~  
27 ~~oxidize eugenol. The~~ rate constants under saturated O<sub>2</sub>, air and N<sub>2</sub> followed the order  
28 of  $k_{O_2} > k_{Air} > k_{N_2}$  for both direct photolysis and OH-initiated oxidation, but changed to  
29  $k_{Air} > k_{N_2} > k_{O_2}$  for <sup>3</sup>C\*-mediated oxidation. pH and dissolved oxygen (DO) levels both  
30 decreased during oxidation, indicating formation of acids and the participation of DO  
31 in oxidation. UV-vis light absorption spectra of the reaction products showed clear  
32 absorbance enhancement in the 300-400 nm range for all three ~~cases~~ sets of experiments  
33 and new fluorescence at excitation/emission=250/(400-500) nm appeared, suggesting  
34 the formation of new chromophores and fluorophores (brown carbon species); and these  
35 species were likely attributed to humic-like substances (HULIS) as shown by the  
36 increases of HULIS concentrations during oxidation. Large mass yields of products  
37 (140%-197%) after 23 hours of illumination were obtained, and high oxidation degrees  
38 of these products were also observed; correspondingly, a series of oxygenated  
39 compounds were identified, and detailed reaction mechanism with functionalization as  
40 a dominant pathway was proposed. At last, dithiothreitol (DTT) assay was applied to  
41 assess oxidation potential of the reaction products, and the end products ~~in~~ of all three  
42 ~~photolysis conditions~~ sets of experiments showed higher DDT consumption rates than  
43 that of ~~the precursor~~ eugenol, indicating more toxic species were produced upon  
44 aqueous oxidation. Overall, our results by using eugenol as a model compound,  
45 underscore the potential importance of aqueous processing of biomass burning  
46 emissions in secondary organic aerosol (SOA) formation, ~~as well as its impacts on~~  
47 ~~particulate matter concentration and toxicity, radiative balance and climate change.~~

48

## 49 **1 Introduction**

带格式的

---

50 Photochemical reactions in atmospheric aqueous phases (cloud/fog droplets and  
51 aerosol water) can affect lifetimes of many organic species, and are an important source  
52 and pathway of secondary organic aerosol (SOA) formation (Vione et al., 2006; Zhao  
53 et al., 2012). Compared to the gasSOA formed via gas-phase photochemical oxidation,  
54 aqueous-phase SOA (aqSOA) is often more oxidized and less volatile, therefore might  
55 play an important role in haze formation, air quality and global climate change (Ervens  
56 et al., 2011; Lim et al., 2010). However, due to complexity of the aqueous reactions and  
57 influencing factors (such as precursors, oxidants, and light intensities), detailed reaction  
58 mechanism, optical property, oxidative potential (OP) and the interplay among them  
59 remain poorly understood.

60 Many laboratory studies have focused on aqueous-phase oxidations of low  
61 molecular weight (LMW) volatile organic compounds (VOCs), such as isoprene,  
62 terpenes ( $\alpha$ -,  $\beta$ -pinene), as well as their gas-phase oxidation products (such as glyoxal,  
63 methylglyoxal, *cis*-pinonic acid and methyl vinyl ketone) (Faust et al., 2017; Herrmann,  
64 2003; Herrmann et al., 2015; Huang et al., 2011; Lee et al., 2012; Zhang et al., 2010).  
65 Recently, aqueous oxidation of semi-/intermediate volatility VOCs (S/IVOCs), such as  
66 the phenolic compounds emitted from combustion or pyrolysis of lignin in biomass,  
67 were also extensively investigated (Barzaghi and Herrmann, 2002; Bonin et al., 2007;  
68 Chen et al., 2020; Gilardoni et al., 2016; He et al., 2019; Jiang et al., 2021; Li et al.,  
69 2014; Li et al., 2021; Ma et al., 2021; Mabato et al., 2022; Smith et al., 2014; Sun et al.,  
70 2010; Tang et al., 2020; Yang et al., 2021; Yu et al., 2016). Generally, chemical  
71 structures of precursors have profound influences on the reaction mechanisms and  
72 products, while effect of oxidants also cannot be neglected. It is evident that liquid water  
73 can contain various types of oxidants, such as singlet oxygen ( $^1\text{O}_2$ ), nitrate radical ( $\text{NO}_3$ ),  
74 hydroxyl radical (OH), and organic triplet excited states ( $^3\text{C}^*$ ), and all can play crucial

---

75 roles in photooxidation reactions (Kaur and Anastasio, 2018; Scharko et al., 2014).  
76 Among them, OH is a ubiquitous oxidant with concentrations of  $10^{-13}$ - $10^{-12}$  mol·L<sup>-1</sup>  
77 (Arakaki et al., 2013; Gligorovski et al., 2015; Herrmann et al., 2003). Hence, aqueous  
78 OH-induced photooxidation has been extensively studied (Chen et al., 2020; Sun et al.,  
79 2010; Yu et al., 2016). Compared to OH oxidation, <sup>3</sup>C\*-initiated aqueous oxidation  
80 (photosensitized ~~reaction~~ reactions) has also attracted attentions in recent years (Ma et  
81 al., 2021; Wang et al., 2021). Several classes of organic compounds in ambient air,  
82 including non-phenolic aromatic carbonyls, quinones, aromatic ketones and nitrogen-  
83 containing heterocyclic compounds, can form <sup>3</sup>C\* after absorbing light (Alegría et al.,  
84 1999; Kaur et al., 2019; Nau and Scaiano, 1996; Rossignol et al., 2014; Chen et al.,  
85 2018). These compounds are termed ~~as~~ photosensitizers. <sup>3</sup>C\* is capable of reacting with  
86 O<sub>2</sub> to produce singlet oxygen (<sup>1</sup>O<sub>2</sub>) and superoxide radicals (O<sub>2</sub><sup>•-</sup>). Various reactive  
87 oxygen species (ROS) can be generated and affect greatly the <sup>3</sup>C\*-initiated aqueous-  
88 phase reactions. Despite some studies demonstrating importance of ROS in  
89 photochemical process (Ma et al, 2021; Wang et al., 2020; Wang et al., 2021; ~~Wu et al.,~~  
90 2021), our current understanding on <sup>3</sup>C\*-initiated oxidation is still limited.

91 Excitation-emission matrix (EEM) fluorescence spectroscopy, as a low-cost, rapid,  
92 non-destructive and high-sensitivity technique, can offer detailed information on  
93 chromophores hence has been widely employed for studies of aquatic dissolved organic  
94 matter (Aryal et al., 2015). Nevertheless, it has not been extensively used in  
95 atmospheric aerosol research (Mladenov et al., 2011). Prior studies have investigated  
96 the relationship between the fluorescence components and chemical structures of  
97 atmospheric aerosols by using high-resolution aerosol mass spectrometry (AMS) and  
98 EEM fluorescence spectroscopy (Chen et al., 2016a; Chen et al., 2016b). An earlier  
99 report from Chang and Thompson (2010) found fluorescence spectra of aqueous-phase

---

100 reaction products of phenolic compounds, which had some similarities with those of  
101 humic-like substances (HULIS), and Tang et al. (2020) reported that aqueous  
102 photooxidation of vanillic acid could be a potential source of HULIS. Chang and  
103 Thompson (2010) also showed that light-absorbing and fluorescent substances  
104 generally had large conjugated moieties (i.e., quinones, HULIS, polycyclic aromatic  
105 hydrocarbons (PAHs)), which can damage human body (Dou et al., 2015; McWhinney  
106 et al., 2013). HULIS are considered as an important contributor to induce oxidative  
107 stress since they can serve as electron carriers to catalyze ROS formation (Dou et al.,  
108 2015; Ma et al., 2019; Huo et al., 2021; Xu et al., 2020), causing adverse health effects.  
109 Dithiothreitol (DTT) assay (Alam et al., 2013; Verma et al., ~~2015a~~2015), as a non-  
110 cellular method, was widely employed to determine oxidation activity and OP of  
111 atmospheric PM (Chen et al., 2019; Cho et al., 2005) for the evaluation of its health  
112 effects. Some other works (Fang et al., 2016; McWhinney et al., 2013; Verma et al.,  
113 2015; Zhang et al., 2022) focused on the link between chemical  
114 ~~composition~~components and OP in PM, and confirmed that several kinds of compounds,  
115 such as quinones, HULIS and transition metals usually had strong DTT activities.  
116 However, DTT method is rarely used to evaluate the OP of aqueous-phase oxidation  
117 products previously (Ou et al., 2021).

118 In the present work, we chose eugenol (allyl guaiacol) as a model compound to  
119 conduct aqueous oxidation experiment. As a representative methoxyphenol emitted  
120 from biomass burning (BB) (Hawthorne et al., 1989; Simpson et al., 2005), it was  
121 widely detected in atmospheric particles. For instance, concentration and emission  
122 factor of this compound from beech wood burning were  $0.032 \mu\text{g}/\text{m}^3$  and  $1.534 \mu\text{g}/\text{g}$ ,  
123 which were twice those of guaiacol ( $0.016 \mu\text{g}/\text{m}^3$  and  $0.762 \mu\text{g}/\text{g}$ ) (Bari et al., 2009).  
124 Eugenol is a semivolatile aromatic compound with a moderate water-solubility (2.46

---

125 g/L at 298 K) ~~to be~~. Chemical characteristics of aqueous reaction products under direct  
126 photolysis (without oxidant) and oxidations by OH radicals and <sup>3</sup>C\* radicaltriplet  
127 states, were comprehensively elucidated by a suite of analytical techniques including  
128 high-performance liquid chromatography (HPLC), ultraviolet and visible (UV-Vis)  
129 spectrophotometry, gas chromatography mass spectrometry (GC-MS), ~~EEM~~ and soot  
130 particle aerosol mass spectrometry (SP-AMS). ~~The relative importance of various ROS~~  
131 ~~species to eugenol degradation was explored.~~ Moreover, light absorption, fluorescent  
132 and oxidative properties of the aqueous oxidation products were also investigated.

## 133 **2 Materials and methods**

### 134 **2.1 Chemicals and reagents**

135 Eugenol (99%), tert-butanol (TBA, 99%), 3,4-dimethoxybenzaldehyde (DMB,  
136 99%), para-benzoquinone (*p*-BQ, 99%), dithiothreitol (99%) and 5,5'-dithiobis-2-  
137 nitrobenzoic acid (DTNB, 99%), 2-nitro-5-thiobenzoic (99%), 5,5-dimethyl-1-  
138 pyrroline N-oxide (DMPO), 2,2,6,6-tetramethylpiperidine (TEMP) were all purchased  
139 from Sigma-Aldrich. Superoxide dismutase (SOD) was purchased from Bovine  
140 Erythrocytes BioChemika. Dichloromethane (HPLC-MS grade, 99%), methanol  
141 (HPLC-MS grade, 99%), acetonitrile (HPLC-MS grade, 98%), hydrogen peroxide  
142 (H<sub>2</sub>O<sub>2</sub>, 35 wt %), and 2,4,6-trimethylphenol (TMP, 99%) were all obtained from  
143 ~~Acros~~ Acros Chemicals. Sodium azide (NaN<sub>3</sub>, 98%) was purchased from J&K Scientific  
144 Ltd. (Beijing, China). All solutions were prepared using ultrapure water (Millipore) on  
145 the days of experiments.

### 146 **2.2 Photochemical oxidation experiments**

---

147 Aqueous-phase photochemical reactions were carried out in a Rayonet  
148 photoreactor (model RPR-200) equipped with 16 light tubes (2 RPR-3000, 7 RPR-3500  
149 and 7 RPR-4190 tubes), which was frequently used to mimic sunlight for  
150 photochemical experiments and was described in details by several groups (George et  
151 al., 2015; Hong et al., 2015; Huang et al., 2018; Jiang et al., 2021; Zhao et al., 2014).  
152 Pyrex tubes containing sample solutions were placed in the center and received  
153 radiation from surrounded lamps of all sides. To ensure mixing of the solution, a fan  
154 and a magnetic stir bar were placed at the bottom of the reaction tube. The solution  
155 temperature was controlled at  $25\pm 2^\circ\text{C}$ . The same photoreactor system and a normalized  
156 distribution of photon fluxes inside the reactor have been reported elsewhere (George  
157 et al., 2015), and the wavelength of light was in the range of 280–500 nm. We only  
158 measured light intensity at the surface of the solution with a radiometer (Photoelectric  
159 instrument factory of Everfine Corporation, Hangzhou, China), which was determined  
160 to be  $\sim 2400 \mu\text{W}/\text{cm}^2$  in the range of 290–320 nm (UVB), lower than the sunlight  
161 intensity ( $6257.1 \mu\text{W}/\text{cm}^2$ ).

162 In this work,  $300 \mu\text{M H}_2\text{O}_2$  and  $15 \mu\text{M DMB}$  were added into solutions as sources  
163 of OH and <sup>3</sup>C\*~~radicals,~~\*, respectively. The initial concentration of eugenol was  $300 \mu\text{M}$ .  
164 For <sup>3</sup>C\*-mediated experiments, solutions were adjusted to pH=3 by sulfuric acid in  
165 order to perform experiments under optimal conditions (Ma et al., 2021; Smith et al.,  
166 2014) since DMB triplet state is protonated to a more reactive form in acidic solution.  
167 We conducted three sets of photolysisoxidation experiments: (A)  $300 \mu\text{M}$  eugenol +  
168  $300 \mu\text{M H}_2\text{O}_2$ , (B)  $300 \mu\text{M}$  eugenol +  $15 \mu\text{M DMB}$ , and (C)  $300 \mu\text{M}$  eugenol without  
169 oxidants. In each series of experiments, a dark control experiment was performed  
170 synchronously with a Pyrex tube wrapped by ~~the~~ aluminum foil. Results showed loss  
171 of eugenol under dark conditions were negligible (data not shown). In addition, to

---

172 evaluate the roles of ROS in eugenol degradation during  $^3\text{C}^*$ -initiated oxidation,  
173 quenching experiments by using specific scavengers to capture different ROS were  
174 performed, namely TBA for OH,  $\text{NaN}_3$  for  $^1\text{O}_2$ , SOD for  $\text{O}_2^-$ , and TMP for  $^3\text{C}^*$ ,  
175 respectively (Pan et al., 2020; ~~Wu~~Chen et al., ~~2021~~2020). For OH-initiated oxidation,  
176 quenching experiments using *p*-BQ for  $\text{O}_2^-$  (Ma et al., 2019; Raja et al., 2005), and  
177 TBA for OH were conducted. For most experiments, solutions were saturated by air  
178 and each experiment presented was repeated three times unless otherwise stated.  
179 Average results with one standard deviation were provided. In order to further evaluate  
180 the role of oxygen in photooxidation, experiments were also conducted by using  
181 different saturated gases (air,  $\text{N}_2$  and  $\text{O}_2$ ).

## 182 2.3 Analytical methods

### 183 2.3.1 Determination of eugenol concentrations

184 Before and during the photochemical experiment, 2 mL of reacted solution was  
185 sampled periodically and subjected to HPLC (LC-10AT, Shimadzu, Japan) analysis to  
186 quantify eugenol concentration. The HPLC was equipped with an InertSustain AQ-C18  
187 reverse phase column (4.6×250 mm, 5.0  $\mu\text{m}$ , Shimadzu) and a UV-vis detector. The  
188 mobile phase was a mixture of acetonitrile/ $\text{H}_2\text{O}$  (v/v: 60/40) at a flow rate of 0.6  
189 mL/min, and the detection wavelength was 280 nm. The first-order kinetic rate constant  
190 of eugenol degradation can be obtained from the slope of plot of  $-\ln(c_i/c_0)$  versus  
191 reaction time as presented in Eq.(1).

$$192 \ln(c_i/c_0) = -kt \quad (1)$$

193 Where  $c_0$  and  $c_i$  are eugenol concentrations (in  $\mu\text{M}$ ) at the initial and reaction time  
194  $t$ , while  $k$  represents the pseudo first-order rate constant- (in  $\text{s}^{-1}$ ).

---

195 **2.3.2 UV-vis and fluorescent spectra**

196 The UV-vis light absorbance spectra of reacted solutions (placed in a 1 cm path  
197 length quartz cuvette) were measured by using an UV-vis spectrophotometer (Specord  
198 210 plus, Analytik Jena., Germany). The instrument has a dual-beam optical system  
199 with tungsten and deuterium lamps as light sources. A reference absorption spectrum  
200 of ultrapure water was carried out in the same cuvette prior to sample analysis for  
201 baseline correction.

202 Immediately after the UV-Vis measurement, the cuvette was transferred to a three-  
203 dimensional EEM fluorescence spectrometer (FluoroMax Plus, HORIBA Scientific).  
204 The ranges of wavelength varied from 200 to 450 nm for excitation wavelengths (Ex)  
205 and from 290 to 650 nm for emission wavelength (Em). Intervals of the excitation and  
206 emission wavelengths were 5 nm and 2 nm, respectively. The reported absorbance and  
207 EEM spectra here are averages of the results from experiments in triplicate.

208 **2.3.3 Determination of HULIS concentrations**

209 Solid phase extraction (SPE) cartridges (CNW Poly-Sery HLB, ~~60mg~~60  
210 mg/cartridge) were used to isolate HULIS from the reaction products. The SPE  
211 cartridge was first rinsed with 1 mL ultrapure water and 3 mL methanol prior to  
212 extraction. The solution was acidified to pH ~2 using HCl and loaded on an SPE  
213 cartridge, which was rinsed with 1 mL ultrapure water again. Next, 3 mL  
214 methanol/ammonia (98:2, v/v) mixture was added into the SPE cartridge to elute  
215 HULIS, and the solution was ~~blew~~blown to full dryness with high purity N<sub>2</sub>, followed  
216 by dilution with ultrapure water to 25 mL for quantification of HULIS using the HPLC  
217 coupled with an evaporative light scattering detector (ELSD3000). Recovery efficiency

218 of the HULIS standard, Suwanne River Fulvic Acid (SRFA), was 75-80% with the  
219 standard deviation of reproducibility less than 5%. More details have been described  
220 elsewhere (Tao et al., 2021).

#### 221 **2.3.4 Oxidative potentials (OPs) potential (OP) based on DTT assay**

222 The ~~OPs~~OP of reaction products ~~were~~was determined by the DTT method (Cho et  
223 al., 2005; Lin and Yu, 2019) with slight improvements. Briefly, 1.2 mL sample solution  
224 was transferred into a 10 mL glass tube, then 6 mL phosphate buffer (0.1 M, pH 7.4)  
225 and 300  $\mu$ L of 2.5 mM DTT were added and mixed thoroughly. The DTT mixed  
226 solution was placed in a 37°C water bath for incubation. Over the course of reactions  
227 that lasted for 150 minutes, 1 mL aliquot of DTT mixture was taken every 30 minutes,  
228 and 100  $\mu$ L of 5 mM DTNB (prepared in 0.1 mM phosphate buffer) was added and  
229 loaded in a centrifuge tube. Next, reactions between DTNB and DTT produced bright  
230 yellow TNB, which was quantified by the UV-Vis spectrometer within 30 minutes.  
231 Finally, we measured the light absorbance ( $A_t$ ) at 412 nm ~~at time t~~ to indirectly quantify  
232 ~~the~~ remaining DTT. Another 1.2 mL ultrapure water instead of sample solution was  
233 treated in the same way and the absorbance was denoted as A as ~~the~~ blank value.  $A_0$   
234 represents the initial light absorbance value. Thus, DTT concentration consumed by the  
235 sample solution ( $M_{DTT}$ ,  $\mu$ M) and that by the blank solution ( $M_{DTT0}$ ,  $\mu$ M) can be  
236 calculated according to Eq.(2) and Eq.(3), respectively.

$$237 \quad M_{DTT} = \frac{A_0 - A_t}{A_0} \times C_{DTT0} \quad (2)$$

$$238 \quad M_{DTT0} = \frac{A_0 - A}{A_0} \times C_{DTT0} \quad (3)$$

239 Here,  $C_{DTT0}$  was the initial DTT concentration in sample solution (100  $\mu$ M in this  
240 work). DTT consumption rates ( $R_{DTT}$  and  $R_{DTT0}$ ) were then obtained from the slopes of  
241 plots of  $M_{DTT}$  and  $M_{DTT0}$  versus incubation times. Experiments of blanks and samples

---

242 were typically run in a triplicate. The reproducibility of the whole analysis showed that  
243 the relative standard deviation of DTT consumption rate was 3-4%.

### 244 **2.3.5 ~~Products~~Product analysis by GC-MS**

245 Reacted solution (about 30 mL) was extracted with 10 mL dichloromethane twice.  
246 The extract was concentrated into 1 mL by blowing N<sub>2</sub> gently, subsequently transferred  
247 to a 2 mL vial, and analyzed by a GC-MS (7890A GC/5975C MS, Agilent) with a DB-  
248 5ms capillary column (30 m×0.25 mm×0.5 μm). The operational conditions were set as  
249 follows: injector was at 200°C; ion source was at 230 °C; column oven temperature was  
250 programmed to be held at 35°C for 4 minutes, then ramped to 250 °C at a rate of  
251 20°C/minute and held for 10 minutes. The recovery efficiency, method detection limits  
252 and quality assurance/quality control have been described in our previous work (Ye et  
253 al., 2020).

### 254 **2.3.6 SP-AMS analysis and mass yields of reaction products**

255 An Aerodyne SP-AMS (Onasch et al., 2012) was applied to analyze the low-  
256 volatility organic products, similar to our previous work (Chen et al., 2020; Ge et al.,  
257 2017). SP-AMS data were acquired in V mode and analyzed by Squirrel v.1.56D and  
258 Pika v1.15D software. The organic fragments were classified into six groups: CH, CHO,  
259 CHN, CHO<sub>2</sub>, CHON and HO. Elemental ratios (oxygen-to-carbon, O/C; hydrogen-  
260 to-carbon, H/C), were calculated according to the method proposed by Canagaratna et  
261 al. (2015).

262 Since the AMS analysis requires nebulization of sample solution into particles  
263 before determination, and quantification of organics was influenced by the atomization  
264 efficiency and carrier gas flow, ~~etc.~~—we thus cannot use SP-AMS measured

265 concentration to quantify the mass of products directly. In this case, according to Li et  
266 al. (2014), we added an internal standard ( $\text{SO}_4^{2-}$ ) prior to AMS analysis, and the mass  
267 ratio of particle-phase organics to  $\text{SO}_4^{2-}$  ( $\Delta\text{Org}/\text{SO}_4^{2-}$ ) can be used to calculate the mass  
268 concentration of products. Furthermore, the mass yield of aqueous-oxidation products  
269 ( $Y_{\text{products}}$ , %), which is the mass of products generated per unit mass of precursor  
270 consumed, can be calculated ~~as~~ according to Eq. (4).

$$271 \quad Y_{\text{products}}(\%) = \frac{(\Delta\text{Org}/\text{SO}_4^{2-})[\text{SO}_4^{2-}]_0}{c_0 M \eta} \times 100\% \quad (4)$$

272 Where  $[\text{SO}_4^{2-}]_0$  is the  $\text{SO}_4^{2-}$  concentration (here  $7.27 \text{ mg}\cdot\text{L}^{-1}$ ),  $C_0$  is the initial eugenol  
273 concentration (in mmol/L),  $M$  is MW of the precursor ( $164 \text{ g/mol}$  for eugenol), and  $\eta$   
274 is the degraded fraction of eugenol.

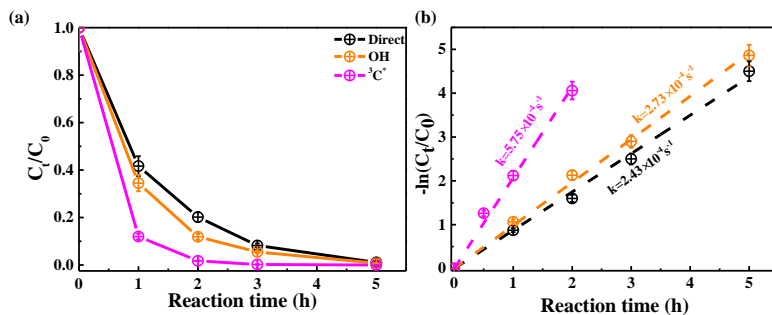

## 275 3 Results and discussion

### 276 3.1 Kinetics of aqueous photooxidation

277 Figure 1 shows unreacted eugenol concentrations ( $c_t$ ) and the negative logarithm  
278 of  $c_t/c_0$  ( $-\ln(c_t/c_0)$ ) as a function of reaction time, respectively. The pseudo first-order  
279 rate constants ( $k$ ) obtained by Eq.(1) were also presented. As described in Fig. 1a,  
280 eugenol concentration decreased to be <20% of the initial concentration in 3 hours,  
281 suggesting ~~photolysis~~ photooxidation was fast under all three reaction conditions. In the  
282 presence of  $^3\text{C}^*$ , eugenol was degraded nearly 100% after 3 hours. Previous study (Chen  
283 et al., 2020) on  $^3\text{C}^*$ -initiated 4-ethylguaiacol oxidation reports a time of 21 hours for a  
284 complete degradation. Apart from difference of precursors, different light irradiation  
285 spectra and stronger energy of light in this work than the previous work might be  
286 responsible for the fast loss of eugenol. The bond dissociation energies (BDEs) are 340  
287 kJ/mol for OH, 374 kJ/mol for C-H in  $-\text{CH}_3$  group, 345 kJ/mol for C=C bond, and 403

288 kJ/mol for C-H in -OCH<sub>3</sub> group, respectively (Herrmann et al., 2003; He et al., 2019).  
289 ~~The lowest BDE was found for the O-H bond and C=C bond.~~ Due to influences of steric  
290 hindrance and intramolecular hydrogen bonding, the H-abstraction from OH group  
291 might not be favorable and the most probable H-abstraction might take place in C=C  
292 of the allyl group. As a result, breakage of C=C into C-C at the allyl group can lead to  
293 the formation of 2-methoxy-4-propyl-phenol (Section 3.6.1). When photon energy is  
294 higher than the BDE, chemical bonds can break, leading to decomposition of  
295 compounds and possibly further mineralization. The ~~energies~~energy of ~~photons~~  
296 ~~at photon of 300 and 350 nm are~~is 412 kJ/mol, ~~and~~ and can break all major bonds in  
297 ~~eugenol, while the energy of 350 nm is 353 kJ/mol, higher than~~being able to break some  
298 ~~of the weakest BDE bonds~~ in eugenol, ~~therefore it as well.~~ Overall, eugenol can be easily  
299 decomposed after absorbing the ~~photon~~photons.

300 As shown in Fig. 1b, the first-order rate constants were  $2.43 \times 10^{-4} \text{ s}^{-1}$ ,  $2.73 \times 10^{-4} \text{ s}^{-1}$ ,  
301  $^1$ , and  $5.75 \times 10^{-4} \text{ s}^{-1}$  for direct photolysis and photooxidations by OH and  $^3\text{C}^*$ ,  
302 respectively.  $^3\text{C}^*$ -initiated photooxidation was quicker than that attacked by OH, likely  
303 due to combined contributions from reactions with  $^1\text{O}_2$ ,  $\text{O}_2^-$  and OH (Section 3.2).  
304 Similar results were found for aqueous phase reactions of three phenols against OH and  
305  $^3\text{C}^*$  by Yu et al. (2016) (Note the initial concentrations of H<sub>2</sub>O<sub>2</sub> and DMB were 100  $\mu\text{M}$   
306 and 5  $\mu\text{M}$ , respectively, with the same ratio as 300  $\mu\text{M}$  H<sub>2</sub>O<sub>2</sub> to 15  $\mu\text{M}$  DMB in this  
307 work)

### 313 3.2 Relative importance of ROS in photooxidation

#### 314 3.2.1 Quenching experiments in $^3C^*$ -initiated photooxidation

315 Relative importance of different ROS in photooxidation can be investigated by  
 316 addition of ~~radical~~ scavengers/quenchers, and then be evaluated based on the different  
 317 degradation efficiencies of eugenol in absence and presence of the corresponding ROS  
 318 quenchers. For each quencher, we conducted several gradient experiments with varying  
 319 molar ratios of eugenol to quencher. The ratios were 0.075:1, 0.15:1, 0.3:1, 0.75:1, 1.5:1  
 320 for quenchers of  $NaN_3$ , TMP and TBA, and 1.2:1, 1.6:1, 2.5:1, 5:1, 10:1 for SOD, which  
 321 were all within the typical ranges of ROS quenching experiments reported previously  
 322 (Zhou et al., 2018). Excess concentrations of quenchers have been added repeatedly to  
 323 ensure the complete reactions between ~~radicals~~ ROS and scavengers. Figure 2 displays  
 324 the impacts of quenchers on eugenol degradation. All rate constants ( $k$ ) with quenchers  
 325 were lower than those of the quencher-free solutions. The optimum molar ratio of  
 326 eugenol to quencher was ~~chosen when selected such that~~ the ~~inhibition degree of~~

327 eugenol degradation ~~unchanged~~ did not change with the increase of added quencher  
 328 (Wang et al., 2021). For example, along with the decrease of molar ratios of eugenol to  
 329 NaN<sub>3</sub> from 1.5:1 to 0.075:1, the ~~inhibitory degree~~ variation of eugenol degradation was  
 330 stabilized at the ratio of 0.15:1, indicating that <sup>1</sup>O<sub>2</sub> has been completely quenched at  
 331 this ratio, therefore a molar ratio of 0.15:1 for NaN<sub>3</sub> was optimal, since excess  
 332 scavenger may generate other products that interfere the existing reactions.  
 333 ~~Similarly~~ Finally, the optimal molar ratios of eugenol to quenchers of TBA, NaN<sub>3</sub>, TMP  
 334 and SOD, were determined to be 1.5, 0.15, 0.075 and 2.5, respectively. Table 1 and Fig.  
 335 S1 compared the rate constants determined under the ratios above and they were in an  
 336 order of TMP<NaN<sub>3</sub><SOD<TBA, suggesting relative importance of generated ROS to  
 337 eugenol degradation was in the order of <sup>3</sup>C\* > <sup>1</sup>O<sub>2</sub> > O<sub>2</sub><sup>•-</sup> > OH. This result suggests that  
 338 <sup>3</sup>C\* plays a major role among all ROS in the photooxidation. Previously, Laurentis et  
 339 al. (2013) reported that 4-carboxybenzophenone (70 μM) could act as <sup>3</sup>C\* and the  
 340 photosensitized degradation was more effective than oxidants such as OH, O<sub>3</sub>, ~~etc.~~;  
 341 Misovich et al. (2021) investigated the aqueous DMB-photosensitized reaction (5 μM,  
 342 same as ~~it~~ in this study) also demonstrated that <sup>3</sup>C\* was the greatest contributor to phenol  
 343 or guaiacyl acetone degradation, followed by <sup>1</sup>O<sub>2</sub>, while both OH and <sup>1</sup>O<sub>2</sub> contributions  
 344 were relatively minor.

345 ~~We~~ To further assess the relative importance of different ROS, we propose to use  
 346 the following Eq.(5) ~~to roughly assess the contribution of for a certain ROS (C<sub>ROS</sub>) to~~  
 347 ~~eugenol degradation~~ rough estimation:

$$348 \quad C_{ROS} = \frac{k_{ROS}}{k} = \frac{(\text{Red}_{ROS} \text{ (in \%)})}{(k - k_{\text{quencher}})} \times 100\%$$

349 (5)

350 Here ~~k<sub>ROS</sub>~~ (in s<sup>-1</sup>) is the ~~rate constant contributed by the ROS, which is defined as the~~  
 351 ~~difference between the~~ original rate constant ~~in of~~ <sup>3</sup>C\*-initiated oxidation (~~for OH-~~

带格式的: 缩进: 首行缩进: 5.5 字符

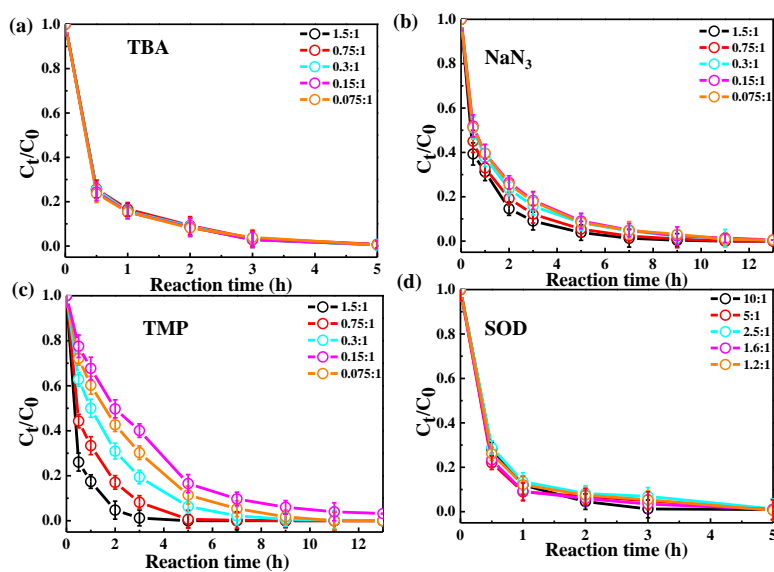

带格式的: 非上标/ 下标

352 initiated oxidation in Section 3.2.2) and  $k_{\text{quencher}}$  (in  $\text{s}^{-1}$ ) is the rate constant –after the  
353 target ROS has been completely scavenged by its ~~corresponding~~ quencher ( $k_{\text{quencher}}$ ).  $k$   
354 and  $k_{\text{quencher}}$  in fact refer to those reported in Fig. S1b. Red<sub>ROS</sub> then refers to the  
355 percentages of reduction due to addition of quencher for a ROS.

356 According to Eq.(5),  ~~$C_{\text{eucRed3C}}^*$~~  was calculated to be ~~0.857~~, ~~therefore contribution~~  
357 ~~of  $^3\text{C}^*$  was estimated to be as high as 85.7%~~. Similarly, the ~~contributions values~~ of  $^1\text{O}_2$ ,  
358  $\text{O}_2^{\cdot-}$  and OH were 80.5%, 61.4% and 53.9%, respectively. ~~The total contribution of the~~  
359 ~~four ROS largely exceeded 100%. This~~ Note Red<sub>ROS</sub> only reflects the relative important  
360 of ROS and it does not corresponds to the exact contribution of that ROS in eugenol  
361 degradation without quenchers. The reason is that although the addition of a ROS  
362 scavenger can be explained eliminate oxidation by the fact that this ROS-scavengers can  
363 actually, but it also significantly interrupt interrupts the radical original chain reactions  
364 as compared to those in the absence of scavengers. For instance, addition of TMP not  
365 only scavenges  $^3\text{C}^*$ , but also inhibits generation of  $^1\text{O}_2$ ,  $\text{O}_2^{\cdot-}$ , etc. These findings suggest  
366 that we cannot directly precisely quantify the contribution of a ROS just on the basis of  
367 its scavenging efficiency, therefore the contributions calculated from Eq.(5) can only  
368 be used to compare the relative importance of different ROS. On the scavenger, and  
369 reactions with other ROS might be enhanced. In this regard, the sum of the four Red<sub>ROS</sub>  
370 values may exceed 100%. Therefore, one should be cautious to apply quenching  
371 approach to quantify the role of ROS in complex reaction system use Red<sub>ROS</sub> as a precise  
372 quantification of the ROS contribution in aqueous oxidation. Determination of ROS  
373 concentrations during oxidation should be instead be an effective way to elucidate the  
374 role of ROS. ~~Therefore~~ Here, we tried to detect in-situ generated OH,  $\text{O}_2^{\cdot-}$  and  $^1\text{O}_2$  during  
375 photochemical reactions using a micro electron spin resonance (ESR) spectrometer  
376 (Bruker Magnettech, Berlin, Germany) with DMPO as the spin trap to form stable

377 DMPO-OH or DMPO-O<sub>2</sub><sup>•-</sup>, with TEMP to capture <sup>1</sup>O<sub>2</sub> to produce TEMP-<sup>1</sup>O<sub>2</sub> spin-  
 378 adduct (TEMPO). The radicals can be identified and quantified by the peak patterns in  
 379 ESR spectra, such as the quarter line with a height ratio of 1:2:2:1 for DMPO-OH,  
 380 1:1:1:1 for DMPO-O<sub>2</sub><sup>•-</sup> and 1:1:1 for TEMP-<sup>1</sup>O<sub>2</sub> (Guo et al., 2021). Unfortunately, OH  
 381 radical cannot be detected since its concentrationsconcentration might be lower than  
 382 the detection limit of the instrument (Fig. S2, ESR spectra of OH). In contrast, we were  
 383 able to detect higherhigh concentrations of <sup>3</sup>C\* and found the intensity of TEMP-<sup>1</sup>O<sub>2</sub>  
 384 signal reached its maximum at 30 minutes, then decreased slowly (Fig. S2, ESR spectra  
 385 of <sup>1</sup>O<sub>2</sub>). Combining the greatestinhibitivegreat quenching effect of TMP with high <sup>1</sup>O<sub>2</sub>  
 386 concentration from ESR method, we can conclude that <sup>3</sup>C\* and <sup>1</sup>O<sub>2</sub> play relatively  
 387 important roles in eugenol photooxidation.

388  
 389 **Figure 2.** Ratio of unreacted eugenol concentration to its initial concentration ( $C_t/C_0$ ) at different  
 390 molar ratios of eugenol to quencher, as a function of reaction time: (a) TBA, (b) NaN<sub>3</sub>, (c) TMP and  
 391 (d) SOD.  
 392

---

393 **3.2.2 Quenching experiments in OH-initiated photooxidation**

394 To examine the contributions of ROS to eugenol degradation for OH-initiated  
395 oxidation, TBA and *p*-BQ as trapping agents were added. Similar to  $^3\text{C}^*$ -initiated  
396 oxidation, several gradient experiments with varying molar ratios of eugenol to  
397 quenchers were conducted. The ratios were set as 6.5:1, 3.2:1, 1.6:1, 1.1:1 and 0.8:1 for  
398 *p*-BQ and 3.0:1, 1.5:1, 0.75:1, 0.3:1 and 0.15:1 for TBA. According to Fig. S3, molar  
399 ratio only had a slight influence on eugenol degradation, although degradation can be  
400 inhibited effectively by quenchers. Thus, we determined the appropriate molar ratios of  
401 0.8 and 0.75 for *p*-BQ and TBA, respectively, as excess scavengers might influence the  
402 chemical reactions.

403 Variations of the rate constants for the aforementioned quenching experiments were  
404 determined, in comparison with those conducted without quenchers, and ~~the~~ results are  
405 listed in Table 1 and presented in Fig. S4. For TBA quenching tests, the rate constant  
406 decreased by 18.7% (from  $2.73 \times 10^{-4} \text{ s}^{-1}$  to  $2.22 \times 10^{-4} \text{ s}^{-1}$ ), showing that OH radical  
407 played a certain role in eugenol photooxidation. Since  $\text{H}_2\text{O}_2$  was mainly photolyzed at  
408 wavelength  $< 300 \text{ nm}$  to generate OH radical, irradiation above 300 nm did not affect  
409 the reaction significantly. The *p*-BQ could quench  $\text{O}_2^{\cdot-}$ , further suppressing the  
410 generation of other ROS (e.g.,  $\cdot\text{HO}_2$ ), therefore the rate constant decreased the most  
411 (from  $2.73 \times 10^{-4} \text{ s}^{-1}$  to  $1.20 \times 10^{-4} \text{ s}^{-1}$ ), suggesting  $\text{O}_2^{\cdot-}$  was important for eugenol  
412 photooxidation. This hypothesis could be further confirmed by the decline of rate  
413 constant under  $\text{N}_2$ -saturated solution (Section 3.2.3). However, it was difficult to detect  
414 both OH and  $\text{O}_2^{\cdot-}$  directly due to their relatively short lifetimes and low concentrations  
415 via ESR in this work.

416

417 **Table 1.** The first-order rate constants of eugenol in the presence of various scavengers. The initial  
 418 conditions were as follows: 300  $\mu$ M eugenol; molar ratios of eugenol to quenchers TBA, NaN<sub>3</sub>,  
 419 TMP and SOD, of 1.5, 0.15, 0.075 and 2.5, respectively; molar ratios of eugenol to quenchers *p*-BQ  
 420 and TBA of 0.8 and 0.75, respectively.

<sup>3</sup> C*-initiated quenching experiments			
Quenchers	ROS	Reaction rate constant $k$ (s <sup>-1</sup> )	Pearson's R <sup>2</sup>
no quencher	-	$5.75 \times 10^{-4}$	0.996
TBA	OH	$2.65 \times 10^{-4}$	0.999
SOD	O <sub>2</sub> <sup>-</sup>	$2.22 \times 10^{-4}$	0.995
NaN <sub>3</sub>	<sup>1</sup> O <sub>2</sub>	$1.12 \times 10^{-4}$	0.999

<i>p</i> -BQ	O <sub>2</sub> <sup>-</sup>	$1.20 \times 10^{-4}$	0.995

421

### 422 3.2.3 Influences of different saturated gases

423 In order to assess the role of O<sub>2</sub> in eugenol photolysis degradation, a series of  
 424 experiments were performed under both O<sub>2</sub>-saturated and N<sub>2</sub>-saturated conditions in  
 425 addition to air. N<sub>2</sub> gas was purged into reaction solution for ~30 minutes before  
 426 experiment to achieve the O<sub>2</sub>-free condition. Figure 3 compared the changes of eugenol  
 427 concentrations and rate constants (~~see insets~~) under the three gas conditions for direct  
 428 photolysis, OH-initiated and <sup>3</sup>C\*-initiated oxidations, respectively. The rate constants  
 429 followed the order of  $k_{O_2} > k_{Air} > k_{N_2}$  under both direct photolysis and OH oxidation,  
 430 providing evidence in support of O<sub>2</sub> being significant for eugenol degradation. This  
 431 might be explained by the fact that O<sub>2</sub> can act as an electron acceptor to generate O<sub>2</sub><sup>-</sup>  
 432 and •HO<sub>2</sub>, and subsequently form H<sub>2</sub>O<sub>2</sub> and OH. For direct photolysis, rate constant  
 433 under O<sub>2</sub>-saturated condition increased 14.4% while it decreased 19.3% under N<sub>2</sub>  
 434 saturation from that under saturated air. For OH-initiated oxidation, the difference of

435 rate constants under three saturated gases became more distinct.

436 On the contrary, rate constants followed the order of  $k_{\text{Air}} > k_{\text{N}_2} > k_{\text{O}_2}$  in  $^3\text{C}^*$ -  
437 initiated oxidation. There are two possible explanations. On one hand, under  $\text{N}_2$ -  
438 saturated condition without oxygen, DMB would involve in reactions (R1-R4), leading  
439 to a more effective generation of  $^3\text{DMB}^*$  therefore a higher degradation efficiency than  
440 under  $\text{O}_2$ -saturated condition. On the other hand, for air/ $\text{O}_2$ -saturated solutions,  
441 irradiation of DMB and eugenol would involve also reactions (R5-R8) in addition to  
442 (R1-R4), and as a result, the amount of  $^3\text{DMB}^*$  ~~radical~~ decreased, due to formation of  
443 other ROS ( $^1\text{O}_2$ ,  $\text{O}_2^-$ , OH, etc) with relatively weak oxidative capacities. In summary,  
444 quenching of  $^3\text{DMB}^*$  by ground state molecular oxygen could account for the low  
445 degradation efficiency in  $\text{O}_2$ -saturated condition.

457

458 **Figure 3.** Ratio of unreacted eugenol concentration to its initial concentration ( $C_t/C_0$ ) as a function  
 459 of reaction time at different saturated gases under (a) direct photolysis (b) OH-initiated oxidation  
 460 and (c)  $^3C^*$ -initiated oxidation. The insets in (a-c) show the corresponding rate constants of (a-  
 461 c) are presented in (d-f) correspondingly.

### 462 3.2.4 Variations of pH and dissolved oxygen

463 The initial pH values of reaction solutions for direct photolysis and OH-initiated  
 464 oxidation were unadjusted, while those that for the  $^3C^*$ -oxidation was adjusted to 3. The  
 465 variation of solution pH is presented in Fig. 4a. The pH values decreased  
 466 dramatically quickly at the beginning of illumination (from 7.4 to  $\sim 5.0$  in the first 1 hour)  
 467 then tended to be flat for both direct photolysis and OH-initiated oxidation. However,

468 little change of pH (less than 0.1 unit) was observed for the  $^3\text{C}^*$ -initiated photooxidation  
469 throughout the oxidation, which can be likely ascribed to its low initial pH of  
470 3. Note a small amount of acids can change solution pH significantly when original pH  
471 is high, but cannot change pH remarkably whenSince the original-solution pH was low.  
472 Therefore, acidic (pH=3), we cannot rule out formation of acidic products (such as  
473 organic acids) during  $^3\text{C}^*$ -initiated oxidation as during direct photolysis and OH-  
474 initiated oxidation.

475 As discussed in Section 3.2.3, oxygen can take part in photochemical reaction to  
476 form ROS, which may in turn destroy the structure of precursor. Here we measured the  
477 oxygen consumption during oxidation through determination of dissolved oxygen (DO)  
478 contents by a dissolved oxygen meter (Seven2Go Pro S9, Zurich, Switzerland). DO was  
479 consumed mainly at the first 1 hour and remained stable afterwards with the increase  
480 of reaction time (Figs. 4b-c and Fig. S5). The amounts of consumed DO followed the  
481 order of  $^3\text{C}^* > \text{OH} > \text{direct}$  photolysis. The maximum consumed DO was found in  $^3\text{C}^*$ -  
482 initiated oxidation, which canmight be explained by the transferconsumption of  
483 electrons from  $\text{O}_2$  that reacts with  $^3\text{C}^*$  to  $\text{O}_2$  to form  $^1\text{O}_2$ , a major contributor to eugenol  
484 degradation, (R5). Obviously, a steady-state DO level was reached when the  
485 consumption rate was equal to the diffusion of  $\text{O}_2$  into the solution (Pan et al., 2020).  
486 Overall, these results re-emphasize that  $\text{O}_2$  can influence eugenol degradation and  
487 radicalchemical transformation via induction of radical chain reactions.

488

489 **Figure 4.** (a) pH values and (b) ~~dissolved~~ dissolved oxygen (DO) contents against reaction time under  
490 ~~three direct~~ photolysis ~~conditions~~, OH-initiated oxidation, <sup>3</sup>C\*-initiated oxidation, and (c) DO  
491 contents during <sup>3</sup>C\*-initiated oxidation under air or O<sub>2</sub>-saturated conditions.

492

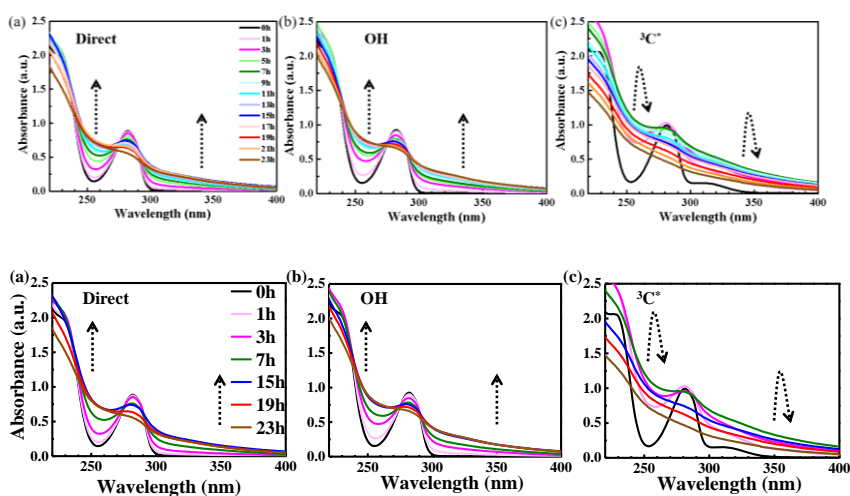

### 493 3.3 Optical properties of reaction products

#### 494 3.3.1 Light-absorbing properties

495 The UV-vis light absorption spectra of the solutions at different reaction times are  
496 presented in Fig. 5. The light absorption by eugenol itself mainly occurs in the range of  
497 260-300 nm ( $n \rightarrow \pi^*$  electronic transition, 270-350 nm), which overlaps with the major  
498 photon fluxes (280 and 500 nm) of our lamp for ~~photooxidations~~ photooxidation.  
499 Therefore, we can clearly observe that the characteristic absorption peak at 280 nm of  
500 precursor decreased with the propagation of direct photolysis (Fig. 5a), similar to that  
501 in OH-initiated photooxidation (Fig. 5b). However, the reaction was quick in the  
502 presence of <sup>3</sup>C\*, and the characteristic absorption peak at 280 nm after 3 hours of  
503 illumination almost disappeared, suggesting nearly a complete loss of eugenol,  
504 consistent with the results in Section 3.1 that more than 99% eugenol was degraded in  
505 3 hours. Additionally, there was an obvious absorption enhancement at longer  
506 wavelengths (300-400 nm) during the photooxidation, whereas eugenol itself did not  
507 absorb light in this range, indicating some light-absorbing products (e.g., brown carbon  
508 (BrC) species) were generated. Aqueous photooxidation of some phenolic compounds  
509 (e.g., vanillic acid) also presented long-wavelength (300-400nm) light absorbance, with  
510 intensity increasing with illumination time (Tang et al, 2020; Zhao et al., 2015). In  
511 addition, there were some differences for light absorbance at wavelength of 300-400  
512 nm in the three ~~eases~~ reaction conditions. For direct photolysis and OH-initiated  
513 oxidation, light absorbance increased during the first 15 hours, then remained at a  
514 plateau until 23 hours. However, for <sup>3</sup>C\*-initiated oxidation, light absorbance increased

515 during the first 7 hours, then decreased slowly afterwards. The different shapes of UV-  
516 vis spectra between OH and  $^3\text{C}^*$  photooxidations indicate formations of different  
517 products.

518 Compared to the light spectrum of eugenol, there were also increases of light  
519 absorbance at  $\sim 260$  nm ( $\pi \rightarrow \pi^*$  electronic transitions) upon aqueous  
520 photolysis/oxidation in all three reaction conditions (Fig. 5), demonstrating the  
521 generation of new substances likely with both aromatic C=C and carbonyl (C=O)  
522 functional groups (Tang et al., 2020). The enhancement at 300-400 nm may point to  
523 products with high MWs and conjugated structures, possibly linking with HULIS or  
524 oligomers. Unfortunately, we were unable to quantify the relative contributions of  
525 individual products to the overall light absorbance between 300 to 400 nm due to lack  
526 of the full speciation of the products and their light absorption spectra.

529 **Figure 5.** UV-vis light absorption spectra of reacted solutions at different reaction times under (a)  
530 direct photolysis, (b) OH-initiated oxidation, and (c)  $^3\text{C}^*$ -initiated oxidation.

### 531 3.3.2 Fluorescence properties

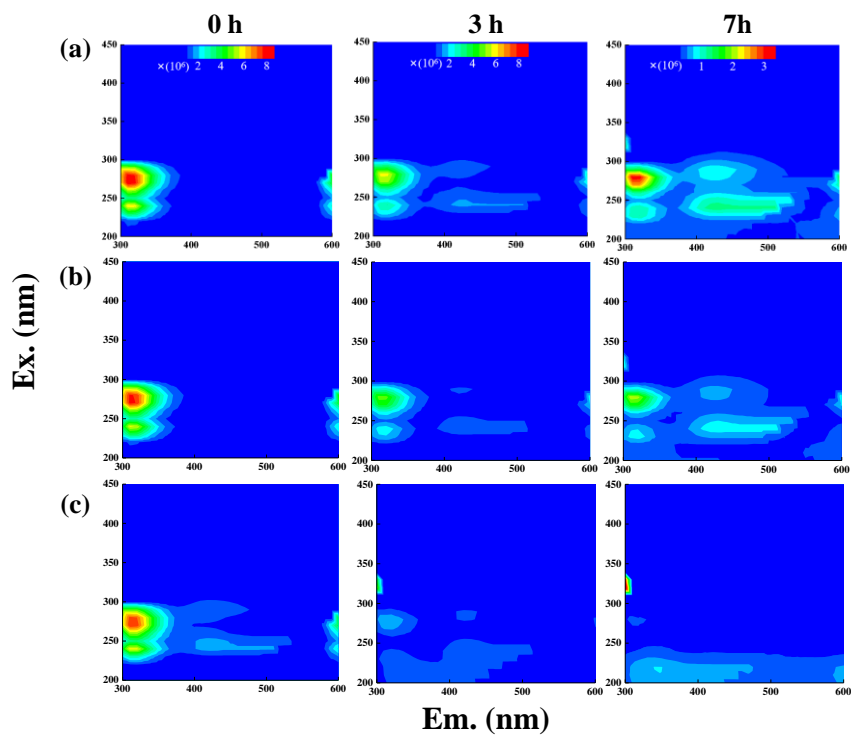

---

532 The fluorescence properties of solutions before (0 hour) and during  
533 ~~photolysisphotooxidation~~ (3 and 7 hours) were investigated via the EEM technique, as  
534 shown in Fig. 6. For comparison, we also presented EEM profiles of pure eugenol (non-  
535 irradiated), pure DMB, and the end solutions (23 hours) of direct photolysis and OH-  
536 initiated oxidation in Fig. S6. The peaks at Excitation/Emission (Ex/Em)=275/313 nm  
537 can be attributed to fluorescence of the phenolic structure of parent substance (eugenol  
538 here), as suggested by Laurentiis et al. (2013). As shown in both Fig. 6 and Fig. S6, the  
539 fluorescence intensity decreased after ~~photolysisoxidation~~ due to eugenol decay, and  
540 the reduction was very fast for  $^3\text{C}^*$ -initiated oxidation. This finding matches with the  
541 fast ~~photolysisdegradation~~ and large rate constant for  $^3\text{C}^*$ -initiated oxidation. The EEM  
542 plots for direct photolysis and OH-initiated oxidation had similar contour patterns as  
543 shown in Figs. 6a and b, although EEM profiles changed significantly with irradiation  
544 time. We also observed distinct fluorescent peaks at Ex/Em=235/(400-500) nm,  
545 indicating that illumination can cause a red shift in fluorescence emission wavelength.  
546 As suggested by Chang et al. (2010), fluorophores at Ex/Em=240/400 nm are linked  
547 with aromatic structures and condensed saturated bonds including polycyclic aromatic  
548 hydrocarbons. Another work (Li et al., 2021) showed that red shift in the fluorescence  
549 spectra was usually related to an increase in the size of ring system and an increase in  
550 the degree of conjugation. Previous studies (Chen et al., 2016a; Chen et al., 2019;  
551 ~~Laurentiis et al., 2013; Wu et al., 2019~~) have reported that fluorescent compounds with  
552 emission wavelength at 400-500 nm ~~may be highly oxygenated species such as were~~  
553 ~~likely linked with~~ HULIS. Additionally, HULIS have two typical fluorescent peaks in  
554 EEM profile at Ex/Em=(200-300)/(400-500) nm and Ex/Em=350/(400-500) nm with  
555 the former one having a higher intensity (Graber and Rudich, 2006; Laurentiis et al.,  
556 2013; Vione et al., 2019; ~~Wu et al., 2021~~). There was also evidence that direct photolysis

---

557 of tyrosine and 4-phenoxyphenol generated HULIS with new fluorescence signals at  
558 Ex/Em=(200-250)/(400-450) nm and 300/(400-450) nm (Bianco et al., 2014). In this  
559 regard, we inferred that new peak at Ex/Em=235/(400-500) nm here was likely  
560 attributed to HULIS. For the  $^3\text{C}^*$ -initiated ~~photolysisoxidation~~, extra fluorescent peaks  
561 at Ex/Em=(220-300)/(400-500) nm appeared in the first 1 hour (data not shown), but  
562 their intensities weakened and gradually disappeared upon prolonged  
563 ~~photolysisreactions~~ (3 hours). Nevertheless, EEM results should be interpreted with  
564 ~~eaveatscaution~~ because many ~~complicated~~ substances might contribute to absorption  
565 and emission at a certain wavelength, and it is hard to distinguish and isolate fluorescent  
566 and nonfluorescent constituents simply via the EEM technique.

567 Another interesting finding was that a small fluorescence peak appeared at  
568 Ex/Em=(300-350)/(300-350) nm in some of the EEM profiles. Specifically, it appeared  
569 earlier for  $^3\text{C}^*$ -oxidation (at 3 hours) than the other two systems, yet its intensity seemed  
570 to be a bit stronger in the end solutions of direct photolysis and OH-oxidation (Fig. S6).  
571 ~~EEM fluorescence spectra of HULIS from fog water are reported to have peaks at~~  
572 ~~shorter excitation and emission wavelengths than those of terrestrial fulvic acids~~  
573 ~~(Graber and Rudich, 2006).~~ Moreover, as suggested by Leenheer and Croue (2003),  
574 fluorescence peak position of the maximum Ex/Em for HULIS with lower MWs would  
575 shift towards lower wavelengths, thus, we inferred fluorescence peak at Ex/Em=(300-  
576 350)/(300-350) nm might be in part attributed to the organic acids with ~~only~~ a few  
577 carbon atoms: ~~(probably C<sub>1</sub>-C<sub>6</sub>)~~. Nevertheless, large uncertainties still exist in using  
578 EEM fluorescence technique to identify molecular compositions of the products due to  
579 lack of standard EEM profiles for specific compounds from aqueous phase oxidation  
580 and clearly more studies are needed in future.

581

582 **Figure 6.** EEM fluorescence spectra of the initial solution (0 hour) and those at different reaction  
 583 time (3 and 7 hours) under (a) direct photolysis, (b) OH-initiated oxidation, and (c)  $^3\text{C}^*$ -initiated  
 584 oxidation.

585

---

586 **3.4 Characteristics of HULIS**

587 The EEM spectra revealed new prominent fluorescent peak at Ex/Em=250/(400-  
588 500) nm, which was likely owing to HULIS. HULIS can be divided into fulvic acid  
589 (water soluble at all pHs), humic acid (base soluble, acid insoluble) and humin  
590 (insoluble at all pHs). In principle, extracted HULIS in this work with polymer-based  
591 HLB SPE packing include LMW organic acids, fulvic acids and other humic substances.

592 Figure 7 presents the measured HULIS concentrations against the reaction time.  
593 The results show clearly that aqueous-phase eugenol oxidation is a source of HULIS,  
594 and the amount increased gradually in the first 7 hours, then remained at a similar level  
595 (about 30 mg/L) for the OH-initiated oxidation. For direct photolysis, HULIS  
596 concentration increased until 11 hours and then became steady at a level around 40  
597 mg/L. For the  $^3\text{C}^*$ -oxidation, HULIS concentration increased to a maximum at 7 hours,  
598 then declined slightly afterwards. A plausible reason of such variabilities is that  
599 generated HULIS was capable of further taking part in photochemical reactions since  
600 it can act as photosensitizer. Moreover, Yu et al. (2016) characterized the products from  
601 aqueous oxidations of phenols by  $^3\text{C}^*$  triplet states and OH radicals, and found both  
602 could produce oligomers and hydroxylated species but the  $^3\text{C}^*$ -oxidation could produce  
603 more of these compounds when 50% of the precursor was reacted. Considering the  
604 large increases of HULIS in the first 7 hours and the much faster increase of  $^3\text{C}^*$ -  
605 oxidation in the first 3 hours shown in Fig. 7, we postulate that HULIS species might  
606 overlap with ~~be some of the products of~~ high MW oligomers, which can in turn  
607 contributed to fluorescence at emission of ~400 nm (Barsotti et al., 2016).

608

609 **Figure 7.** HULIS concentrations as a function of reaction time for the three conditions under direct  
 610 photolysis, OH-initiated oxidation and <sup>3</sup>C\*-initiated oxidation.

### 611 3.5 Mass yield and oxidation degree of reaction products

#### 612 3.5.1 Mass yields

613 HULIS is only a subset of the products from aqueous oxidation, and here we used  
 614 AMS to further quantify the total reaction products. Figure 8a shows SP-AMS  
 615 measured organic mass profiles (normalized by sulfate mass,  $\Delta\text{Org}/\text{SO}_4^{2-}$ ) against the  
 616 reaction time. As the reaction propagated,  $\Delta\text{Org}/\text{SO}_4^{2-}$  increased continuously in <sup>3</sup>C\*-  
 617 initiated system. Nevertheless it arose stepwise and reached a maximum at 19 hours,  
 618 then remained at a plateau for the direct photolysis and OH-mediated oxidation. Figure  
 619 8b illustrates the calculated mass yields at different reaction times. The mass yields  
 620 after 1 hour of illumination were in the ranges of 46.2%-196.5%, 22.1%-144.9%,  
 621 19.3%-140.1% for <sup>3</sup>C\*-oxidation, OH-oxidation and direct photolysis, respectively. For  
 622 the same oxidation time, mass yield from <sup>3</sup>C\*-oxidation was generally higher than those  
 623 from OH-oxidation and direct photolysis. There are two plausible reasons for high mass  
 624 yield of <sup>3</sup>C\*-initiated oxidation. First, oxidation by <sup>3</sup>C\* was more efficient to form  
 625 oligomers and functionalized/oxygenated products (Richards-Henderson et al., 2014;

626 Yu et al., 2016). Higher oxidative degree of products from  $^3\text{C}^*$ -initiated photooxidation  
627 (see Sec.3.5.2) supports this hypothesis. Secondly, more light-absorbing products  
628 formed during initial stage of  $^3\text{C}^*$ -oxidation (Fig. 5c) may accelerate oxidation by  
629 acting as photosensitizers (Tsui et al., 2018).

630 The product mass yields obtained in this work (~20%-197%) overall agree with  
631 those reported previously for phenolic compounds. For examples, Huang et al. (2018)  
632 reported mass yields of 30-120% for syringaldehyde and acetosyringone; Smith et al.  
633 (2014) found that mass yields of aqSOA from three phenols with  $^3\text{C}^*$  were nearly 100%,  
634 and Ma et al. (2021) reported a yield ranging from 59 to 99% for six highly substituted  
635 phenols with  $^3\text{C}^*$ ; Mass yields of SOA from three benzene-diols were near 100% with  
636 both OH and  $^3\text{C}^*$  oxidants (Smith et al., 2015); Direct photolysis of phenolic carbonyls,  
637 and oxidation of syringol by  $^3\text{C}^*$ , had SOA mass yields ranging from 80 to 140% (Smith  
638 et al., 2016). Our previous study on eugenol OH oxidation illuminated by a 500 W Xe  
639 lamp reported a mass yield of ~180% (Ye et al., 2020), slightly higher than the value  
640 determined here owing to different ~~simulated lights~~ light wavelengths/intensities.

641  
642 **Figure 8.** Variations of the organic mass normalized by sulfate (a) ( $\Delta\text{Org}/\text{SO}_4^{2-}$ ) and (b) mass yields  
643 of reaction products with reaction time under ~~three conditions~~ direct photolysis, OH-initiated  
644 oxidation and  $^3\text{C}^*$ -initiated oxidation.

645

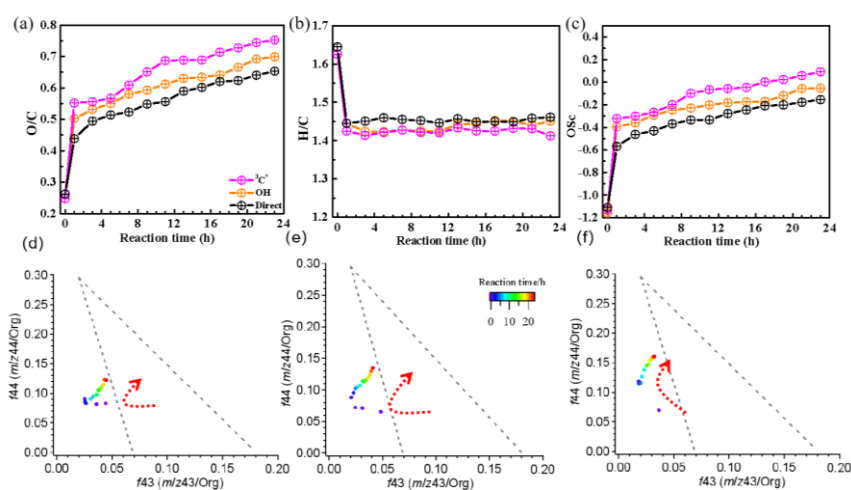

### 646 3.5.2 Oxidation degree

647 In order to further probe oxidation levels of the reaction products, O/C derived  
648 from SP-AMS mass spectrum of the organics was used to represent the oxidation degree  
649 of products. In addition, carbon oxidation state (OSc, defined as  $2 \times \text{O/C} - \text{H/C}$ ) (Kroll  
650 [et al., 2011](#)) was also calculated (Kroll et al., 2011). Figures 9a-c depict variations of  
651 the elemental ratios (O/C and H/C) and OSc during oxidations. Dramatic increases of  
652 O/C and OSc during the initial stage of oxidation (within 1 hour) were observed, with  
653 O/C changing from 0.26 to 0.65, from 0.26 to 0.70, from 0.25 to 0.75, as well as OSc  
654 from -1.11 to -0.15, from -1.16 to -0.05, from -1.13 to 0.09 for direct photolysis, OH-  
655 oxidation and  $^3\text{C}^*$ -oxidation, respectively. The O/C was lower than those of other  
656 phenolic aqSOA (Yu et al., 2014) due to different substituted groups in aromatic ring of  
657 the precursors. Both O/C and OSc gradually increased, while H/C changed little after 1  
658 hour. The enhancements of OSc in the end were 1.22, 1.11 and 0.86 for  $^3\text{C}^*$ -initiated  
659 oxidation, OH-initiated oxidation and direct photolysis, respectively.

660 Furthermore, the  $f_{44}$  vs.  $f_{43}$  diagram (“triangle plot”) can be used to demonstrate  
661 the evolution of SOA during oxidation (Ng et al., 2010). The  $f_{44}$  and  $f_{43}$  are defined as  
662 the ratios of signal intensities of  $m/z$  44 (mainly  $\text{CO}_2^+$ ) and 43 (mainly  $\text{C}_2\text{H}_3\text{O}^+$ ) to the  
663 total organics. The results that the  $f_{44}$  increased continuously (moved upwards) during  
664 both OH and  $^3\text{C}^*$  oxidations, indicating persistent formation of highly oxygenated  
665 compounds including organic acids, such as formic acid and oxalic acid (Sun et al.,  
666 ~~2010). Concentrations of organic acids increased with photochemical reactions can~~  
667 ~~support this assumption (data not shown).~~ Note the  $f_{44}$  enhancement was much more  
668 significant for  $^3\text{C}^*$  oxidation (from 0.07 to 0.16) than direct photolysis (from 0.07 to  
669 0.12) and OH oxidation (from 0.07 to 0.13), consistent with the behaviors of its higher  
670 O/C and OSc. The  $f_{43}$  value decreased in the first stage (1-3 hours) and then increased  
671 at later stages. The final  $f_{43}$  values were almost the same as those of the initial solutions.

672 and were small. As a result, all data points located outside the  $f_{44}$  vs.  $f_{43}$ -space  $f_{43}$  region  
673 (bounded by the two dash lines in Figs. 9d-f) for ambient aerosols established by Ng et  
674 al. (2010) for ambient aerosols, owing to the relatively low  $f_{43}$ -values.

675 In summary, our results shown here demonstrate that aqueous phase eugenol  
676 photochemical oxidation can generate highly oxygenated products and hence increase  
677 the degree of oxygenation of overall SOA.

678 **Figure 9.** Variations of the elemental ratios of (a) O/C, (b) H/C and (c) the oxidation state (OSc) as  
679 a function of reaction time, and the  $f_{44}$  vs.  $f_{43}$  plots of reaction products under (a) direct photolysis,  
680 (b) OH-initiated oxidation, and (c)  $^{13}\text{C}^*$ -initiated oxidation.

## 682 3.6 Molecular characterization of reaction products and proposed reaction 683 mechanism

### 684 3.6.1 Major products identified by GC-MS

685 SP-AMS was limited to probe bulk composition of low-volatility oxidation  
686 products, thus the molecular-level characterization of products was performed by using  
687 GC-MS here. The total ion chromatograph (TIC) of GC-MS on the solutions before

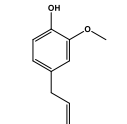

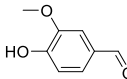

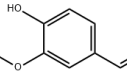

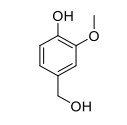

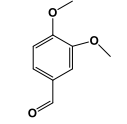

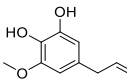

---

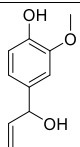

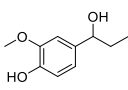

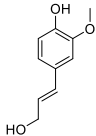

688 illumination (0 hour) and at illumination times of 11 and 23 hours for the  $^3\text{C}^*$ -initiated  
689 photooxidation is shown in Fig. S7. As shown in Fig.S7, eugenol (retention time (RT)  
690 at 11.50 min) loss was more than 90% at 11 hours, which could be confirmed by the  
691 experimental data reported in Section 3.1. Comparison of products at 11 hours and 23  
692 hours showed no significant difference. Similar to aqueous photochemical oxidation  
693 with OH (Ye et al., 2020), a series of products were identified and listed in Table 2.  
694 Except 5-allyl-3-methoxybenzene-1,2-diol (MW 180, RT=12.59 min), the other eight  
695 products were detected for both OH and  $^3\text{C}^*$ -initiated photooxidations. Some of them  
696 (Eugenol, DMB, product 1, 2, 5) were identified by using certified reference materials,  
697 some of them (product 3, 4, 6, 7, 8, 9) were inferred according to the molecular ion  
698 peaks and fragments from GC-MS, based on spectra from the NIST database (Stein,  
699 2014) and on the reactants and reaction conditions.

700 We also found 4-(1-hydroxypropyl)-2-methoxyphenol (product 8) was relatively  
701 abundant (Fig.S7), suggesting functionalization might dominates as compared to  
702 oligomerization and fragmentation. Products were mainly from addition/elimination of  
703 hydroxyl (-OH), methoxyl (-OCH<sub>3</sub>) to benzene ring or allyl group and further oxidized  
704 to carbonyl or carboxyl compounds. As suggested by Bonin et al. (2007), the OH-  
705 addition to the aromatic ring of phenol preferentially takes place at the ortho (48%) and  
706 the para (36%) positions, leading to the formation of OH-adduct product 6 (5-allyl-3-  
707 methoxybenzene-1,2-diol). Notably, dimers and ring-opening products were not  
708 observed, but they cannot be excluded since they would be probably out of the detection  
709 of GC-MS technique (Vione et al., 2014).

710

711 **Table 2.** Major reaction products identified via GC-MS

	<b>RT (min)</b>	<b>Name*</b>	<b>Proposed chemical structure</b>	<b>Chemical formula</b>	<b>Nominal MW (g/mol)</b>
Product 1	10.68	4-allylphenol		C <sub>9</sub> H <sub>10</sub> O	134
Precursor	11.50	Eugenol		C <sub>10</sub> H <sub>12</sub> O <sub>2</sub>	164
Product 2	11.81	4-hydroxy-3-methoxybenzaldehyde		C <sub>8</sub> H <sub>8</sub> O <sub>3</sub>	152
Product 3	12.06	(E)-2-methoxy-4-(prop-1-en-1-yl)phenol		C <sub>10</sub> H <sub>12</sub> O <sub>2</sub>	164
Product 4	12.11	4-(hydroxymethyl)-2-methoxyphenol		C <sub>8</sub> H <sub>10</sub> O <sub>3</sub>	154
Product 5	12.18	2-methoxy-4-propylphenol		C <sub>10</sub> H <sub>14</sub> O <sub>2</sub>	166
Photosensitizer	12.29	3,4-dimethoxybenzaldehyde (DMB)		C <sub>9</sub> H <sub>10</sub> O <sub>3</sub>	166
Product 6**	12.59	5-allyl-3-methoxybenzene-1,2-diol		C <sub>10</sub> H <sub>12</sub> O <sub>3</sub>	180

Product 7	12.65	4-(1-hydroxyallyl)- 2-methoxyphenol		C <sub>10</sub> H <sub>12</sub> O <sub>3</sub>	180
Product 8	12.79	4-(1- hydroxypropyl)-2- methoxyphenol		C <sub>10</sub> H <sub>14</sub> O <sub>3</sub>	182
Product 9	12.91	(E)-4-(3- hydroxyprop-1-en-1- yl)-2-methoxyphenol		C <sub>10</sub> H <sub>12</sub> O <sub>3</sub>	180

712 \*Precursor (eugenol) and triplet precursor (DMB) are also shown.

713 \*\*This compound was only identified in <sup>3</sup>C\*-oxidation solution.

### 714 3.6.2 Reaction mechanism

715 The reaction pathways of <sup>3</sup>C\*-initiated photooxidation of eugenol are  
 716 demonstrated in Scheme 1 based on the products identified by GC-MS. The  
 717 other intermediates and the potential pathways were proposed according to the  
 718 identified products and the reaction rationality from the starting reactant. To better  
 719 depict the mechanism, DMB was expressed as [RCHO] and eugenol as Ph-R for  
 720 simplicity. ~~First,~~ [RCHO] absorbs light and undergoes excitation to <sup>1</sup>[RCHO]\*, then  
 721 experiences the intersystem crossing (ISC) to form <sup>3</sup>[RCHO]\*. <sup>3</sup>[RCHO]\* can  
 722 participate in subsequent reactions via three channels. First, it can react with O<sub>2</sub> to form  
 723 <sup>1</sup>O<sub>2</sub> via energy transfer. Secondly, it can transform to [RCHO]\*, subsequently reacts  
 724 with O<sub>2</sub> to generate O<sub>2</sub><sup>-</sup> via electron transfer, which can disproportionate to H<sub>2</sub>O<sub>2</sub>. The  
 725 decomposition of H<sub>2</sub>O<sub>2</sub> can generate OH radical. Thirdly, the <sup>3</sup>[RCHO]\* can react with  
 726 Ph-R to form [Ph-R•] via H-abstraction. The cleavage of [Ph-R•] to free radical segment

---

727 (such as  $\text{CH}_2\text{CH}\cdot$  or  $\text{CH}_3\text{O}\cdot$ ) takes place, then an additional hydrogen transfer could  
728 occur, resulting in a 2H-addition to the new intermediate to form 4-allyl-phenol  
729 (product 1). Similarly, when the  $\text{CH}_2\text{CH}\cdot$  is lost from  $[\text{Ph-R}\cdot]$ , an addition of  $\text{H}_2\text{O}$   
730 would happen on the new compound (product 4) and further oxidized to 4-hydroxy-3-  
731 methoxybenzaldehyde (product 2). Another possibility is the intermediate  $[\text{Ph-R}\cdot]$  can  
732 resonate to several different isoelectronic species, the radical position changes to  
733 aromatic ring or allyl group site, which would couple with  $\text{HO}\cdot$  to form hydroxylated  
734 eugenol monomer (product 6, 7, 9 MW=180). Consequently, the isoelectronic species  
735 at allyl group site could also abstract a hydrogen to form isoeugenol (product 3  
736 MW=164). Also, breakage of  $\text{C}=\text{C}$  into  $\text{C}-\text{C}$  and 2H-addition at allyl group site could  
737 form 2-methoxy-4-propyl-phenol (product 5, MW=166). Besides, the  $\text{C}=\text{C}$  breaking  
738 intermediate can couple with  $\text{HO}\cdot$  to form 4-(1-hydroxypropyl)-2-methoxyphenol  
739 (product 8, MW=182). In conclusion,  $^3\text{C}^*$  can directly oxidize eugenol to form SOA  
740 products or small molecular compounds, or indirectly oxidize eugenol via energy  
741 transfer, electron transfer, hydrogen abstraction, proton-coupled electron transfer or  
742 other radical chain reactions.

743 The organic groups, such as methoxy, allyl groups can be eliminated from  
744 aromatic ring, which then participate in photochemical reaction, resulting in generation  
745 of dimers, small organic acids,  $\text{CO}_2$  and  $\text{H}_2\text{O}$ , etc. Dimers previously reported from  
746 aqueous reaction of 4-methylsyringol with OH were not detected via GC-MS in the  
747 present work but dimer fragment ions ( $\text{C}_{20}\text{H}_{22}\text{O}_4^+$ ) were detected by SP-AMS with trace  
748 amounts. Functionalization due to the additions of hydroxyl, carbonyl functional groups  
749 to the aromatic rings could account for the enhancement of light absorption at  
750 wavelength of 300-400 nm. However, polar high MW organic acids were not detected  
751 likely due to the limitation of GC-MS technique.

752

753 **Scheme 1.** Proposed reaction mechanism of  $^3C^*$ -initiated photooxidation of eugenol. The red ~~texts~~  
 754 ~~represent~~text represents the ~~products listed in Table 2~~precursor, and the compounds labeled by  
 755 Product 1-9 are those identified by GC-MS-(Table 2).

756 **3.7 Oxidative potential (OP) of reaction products**

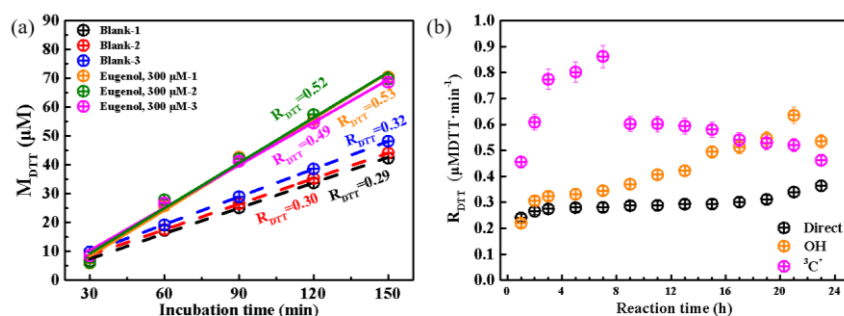

757 ~~Previous laboratory studies (Verma et al., 2015b; Xu et al., 2020) have confirmed~~  
 758 ~~that HULIS is a major constituent contributing to ROS generation potential. As HULIS~~  
 759 ~~is an important fraction of the products from aqueous photooxidation of eugenol in this~~

760 ~~work (Fig. 7), here we investigated the links between the OPs and reaction products.~~

761 The OP of oxidation products can be represented by the consumption rate of DTT  
762 concentration ~~per minute~~, defined as  $R_{DTT}$ . Figure 10a shows the DTT consumed mass  
763 ( $M_{DTT}$ ) as a function of incubation times (0, 30, 60, 90, 120 and 150 min) for a triplicate  
764 sample (300  $\mu$ M eugenol) and blank (ultrapure water).  $M_{DTT}$  values for both blank and  
765 eugenol were proportional to incubation time, indicating that ROS-generating  
766 substances in reaction solution act only as catalyst and itself was not consumed. The  
767 slopes represent DTT consumption rates, which are also illustrated in Fig. 10a. Average  
768  $R_{DTT0}$  (blank) was 0.31  $\mu$ M/min and  $R_{DTT}$  for initial 300  $\mu$ M eugenol (before experiment)  
769 was 0.52  $\mu$ M/min. Since self-oxidation of DTT might lead to the consumption of DTT  
770 in ultrapure water, final DTT consumption rate of reacted solution after  
771 ~~photolysisoxidation~~ was then blank-corrected by subtracting the average  $R_{DTT0}$ .

772 Figure 10b shows changes of blank-corrected  $R_{DTT}$  with ~~photolysisreaction~~ time  
773 for direct photolysis, OH-initiated oxidation and  $^3C^*$ -initiated oxidation, respectively.  
774 The  $R_{DTT}$  value of  $^3C^*$ -oxidation products increased quickly and reached the maximum  
775 (0.9) at 7 hours, then decreased slowly and its end value was lower than that from OH-  
776 oxidation. The  $R_{DTT}$  value of OH-oxidation products on the other hand increased slowly  
777 and reached the maximum at 21 hours. The  $R_{DTT}$  value of products from direct  
778 photolysis increased continuously but also slowly to  $\sim$ 0.36 till the end of oxidation.  
779 Nevertheless, we can see that the final  $R_{DTT}$  values were all higher than that of ~~initial~~  
780 eugenol, proving that aqueous-phase processing can generate products with higher OP,  
781 resulting in more health hazards than the precursor does. The DTT consumption rates  
782 are comparable to those using the same DTT method (Charrier and Anastasio, 2012;  
783 Lin and Yu, 2019). ~~This finding further indicates the effectiveness of DTT method to~~  
784 ~~represent OP.~~The weak correlation was found between HULIS concentration and  $R_{DTT}$ ,

785 implying that OP was not only dependent upon HULIS. Moreover, HULIS with diverse  
 786 molecular structures also exhibit different ROS-generation potentials (Kramer et al.,  
 787 2016), therefore the HULIS as an ensemble may not correlate well with OP.

788  
 789 **Figure 10.** (a) DTT consumed mass versus incubation times for blank (ultrapure water) and 300  $\mu\text{M}$   
 790 eugenol solutions in a triplicate, and (b) blank-corrected DTT consumption rates versus reaction  
 791 time for direct photolysis, OH-initiated oxidation and  $^3\text{C}^*$ -induced oxidation.

#### 792 4. Atmospheric implications

793 The high mass yields of aqueous-phase photooxidation of eugenol (exceeding 100%  
 794 after 23 hours of illumination) ~~studied found~~ here are similar or even higher than those  
 795 previously reported yields of a number of phenolic compounds (e.g., Smith et al., 2014,  
 796 2015, 2016; Ma et al., 2021), which re-emphasizes the importance of biomass burning  
 797 (BB) to SOA budget (Gilardoni et al., 2016), particularly in regions or periods with  
 798 significant BB activities. ~~Compared to simple phenols (such as syringol) that are only~~  
 799 ~~present in cloud/fog waters, the highly substituted phenols are able to significantly~~  
 800 ~~partition into aerosol water too (Ma et al., 2021). Since the highly substituted phenols~~  
 801 ~~can take up roughly 30–45% of total phenols emitted from wood burning (Schauer et~~  
 802 ~~al., 2001), our results further imply that aqueous production of SOA from BB emissions~~  
 803 ~~can not only occur in fog/cloud conditions, but also in common humid weather~~

---

804 ~~conditions, highlighting the general importance of aqueous oxidation pathway to SOA.~~

805 ~~Our~~In addition, our study here used 300  $\mu\text{M}$   $\text{H}_2\text{O}_2$  and 15  $\mu\text{M}$  DMB as sources of  
806 OH and  $^3\text{C}^*$ , and  $^3\text{C}^*$ -mediated oxidation appeared to be faster than OH-initiated  
807 oxidation of eugenol. Of course, whether or not  $^3\text{C}^*$  is more important than OH in real  
808 atmosphere depends upon their concentrations. OH and  $^3\text{C}^*$  are difficult to measure and  
809 concentrations vary greatly in real atmospheric samples. Herrmann et al. (2010)  
810 estimated an average OH level of  $0.35 \times 10^{-14}$  M in urban fog water; Kaur and Anastasio  
811 (2018) measured  $^3\text{C}^*$  concentration to be  $(0.70-15) \times 10^{-14}$  M, 10-100 times higher than  
812 ~~the~~ co-existing OH in ambient fog waters; Kaur et al. (2019) determined both OH and  
813  $^3\text{C}^*$  concentrations in PM extracts, OH steady-state concentration was  $4.4(\pm 2.3) \times 10^{-16}$   
814 M, similar to its level in fog, cloud and rain, while  $^3\text{C}^*$  concentration was  $1.0(\pm 0.4)$   
815  $\times 10^{-13}$  M, a few hundred times higher than OH and nearly double its average value in  
816 fog. Therefore, together with these measurements, our findings signify a likely more  
817 important role of  $^3\text{C}^*$  than OH in aqueous-phase (especially aerosol water) reactions.

818 ~~In addition~~However, the liquid water content of aerosol is typically  $\sim 10000$  times  
819 ~~smaller than that of cloud (for instance,  $\sim 50 \mu\text{g m}^{-3}$  versus  $0.5 \text{ g m}^{-3}$ ). Even if the~~  
820 ~~reaction rates in aerosol water were 10 times higher than those in cloud water, the~~  
821 ~~overall importance of aqueous reactions initiated by the same oxidant in aerosol phase~~  
822 ~~would be still  $\sim 1000$  times smaller than it in cloud water. Moreover,~~ quenching  
823 experiments reveal that  $\text{O}_2$  can inhibit eugenol degradation by effectively scavenging  
824  $^3\text{C}^*$  ~~radical~~ while it can promote degradation by fostering ~~radical~~-chain reactions in OH-  
825 induced oxidation, which offer insights to ~~the~~ control of reaction pathways by  
826 regulating ~~the~~ ROS generations; of course, such operation calls for application of highly  
827 sensitive EPR method.

828 Eugenol has a strong light absorption peak around 280 nm, therefore it can

---

829 ~~photolyze itself~~undergo direct photolysis, and addition of OH or other photosensitizers  
830 (<sup>3</sup>C\*) can gradually diminish its light absorption around 280 nm, but increase the  
831 absorption in visible light range (>300 nm). In the meantime, HULIS was generated  
832 continuously, and GC-MS identified a number of high MW organic products, in line  
833 with those detected in earlier aqueous photooxidation of phenolic compounds (Jiang et  
834 al., 2021; Misovich et al., 2021; Tang et al., 2020; Yu et al., 2014). Overall, our work  
835 demonstrates that aqueous oxidation of BB emissions is a source of BrC, and this BrC  
836 may act as photosensitizer to oxidize other species; a portion of this BrC might be  
837 HULIS, and some high MW aromatic compounds are a subset of this HULIS. However,  
838 a recent study by Wang et al. (2021) shows that fossil fuel derived OA (FFOA) can be  
839 an effective precursor of aqSOA, but the aqSOA became less light-absorbing than the  
840 FFOA. ~~Aqueous oxidation of 4-nitrophenol with OH can lead to a photobleaching effect~~  
841 ~~too (Witkowski et al., 2022).~~ These contrasting results indicate that contribution of  
842 aqueous oxidation to BrC is largely dependent upon the precursors; molecular  
843 structures of major chromophores, changes of the structures upon oxidation as well as  
844 their interplay with light absorptivity should be carefully investigated to achieve a full  
845 understanding of the impacts of aqueous processing on air quality, radiative forcing and  
846 climate change.

847 Investigations on the OPs of reaction products from eugenol photooxidation ~~in all~~  
848 ~~three conditions~~ show that aqueous processing can produce more toxic products than  
849 ~~the~~ precursor. This result is in agreement with our previous work on resorcinol,  
850 hydroquinone and methoxyhydroquinone (Ou et al., 2021). Although more studies on  
851 a broad spectrum of atmospherically relevant species and multiple indicators of toxicity  
852 are clearly needed, our findings here underscore the potential of aqueous processing on  
853 the enhancement of particle toxicity. ~~Considering high PM concentration is often~~

---

854 ~~accompanied with cold and humid weather conditions, the additional adverse health~~  
855 ~~effects caused by aqueous oxidation may amplify the health hazards of PM pollution.~~

## 856 **5 Conclusions**

857 This study comprehensively investigated the aqueous photooxidation of eugenol  
858 upon direct photolysis and attacks by OH radicals and  $^3\text{C}^*$  radicaltriplet states. By  
859 using a suite of techniques, the decay kinetics of eugenol, chemical, optical properties  
860 as well as toxicity of reaction products were ~~systematically~~ studied. The first-order  
861 ~~photolysis~~ rate constants followed the order of  $^3\text{C}^* > \text{OH} > \text{direct photolysis}$  (300  $\mu\text{M}$   
862  $\text{H}_2\text{O}_2$  and 15  $\mu\text{M}$  DMB as sources of OH and  $^3\text{C}^*$ ). Further quenching experiments on  
863 different ROS during  $^3\text{C}^*$ -mediated oxidation showed that  $^3\text{C}^*$  was the major  
864 contributor, followed by  $^1\text{O}_2$ ,  $\text{O}_2^-$  and OH;  $\text{O}_2^-$  played a more important role than OH  
865 during OH-initiated oxidation. ~~Photolysis~~The rate constants under saturated  $\text{O}_2$ , air and  
866  $\text{N}_2$  followed the order of  $k_{\text{O}_2} > k_{\text{Air}} > k_{\text{N}_2}$  for both direct photolysis and OH-initiated  
867 oxidation, but changed to  $k_{\text{Air}} > k_{\text{N}_2} > k_{\text{O}_2}$  for  $^3\text{C}^*$ -mediated oxidation.  $\text{O}_2$  appeared to  
868 be a scavenger of  $^3\text{C}^*$  therefore suppressing  $^3\text{C}^*$  oxidation while it could promote  
869 generation of OH thus accelerate OH-mediated oxidation. pH and DO levels both  
870 decreased during oxidation, indicating formation of acids and a certain role of DO in  
871 oxidation.

872 Eugenol itself can absorb lights significantly around 280 nm, and aqueous  
873 oxidation gradually decrease this absorption of UV light but enhanced the absorbance  
874 in the visible light range (mainly 300-400 nm), indicative of the generation of BrC  
875 species. These species were likely linked with HULIS, as HULIS concentration  
876 increased during the course of oxidation, in particular for the initial stage of  $^3\text{C}^*$ -  
877 mediated reactions. The final mass yields of reaction products (after 23 hours of

---

878 irradiation) were 140.1%, 144.9% and 196.5% for direct photolysis, OH-oxidation and  
879 <sup>3</sup>C\*-oxidation, respectively. Oxidation degrees of the products increased continuously  
880 with the illumination time, indicating persistent formation of highly oxygenated  
881 compounds, especially during <sup>3</sup>C\*-mediated reactions. Molecular characterization by  
882 GC-MS identified a series of oxygenated compounds, allowing us to propose the  
883 detailed oxidation mechanism. Functionalization appeared to be a dominant pathway to  
884 form the observed species.

885 DTT method was used to assess ~~OPsOP~~ of the reaction products. The end products  
886 in all three ~~casesets of experiments~~ showed higher DDT consumption rates than that  
887 of the precursor; products from <sup>3</sup>C\*-oxidation showed particularly fast increase in the  
888 first few hours of reactions. This result demonstrates that species that are more toxic  
889 than its precursors could be produced upon aqueous oxidation, indicative of the  
890 potential toxic effects induced by aqueous processing. ~~Overall, by using eugenol as a~~  
891 ~~model compound of BB emissions, our findings highlight the importance of aqueous~~  
892 ~~oxidation of BB emissions to SOA formation, its potentially important role in affecting~~  
893 ~~radiative balance and climate through formation of BrC, as well as possible additional~~  
894 ~~adverse health effects. Such effects should be considered in air quality or climate~~  
895 ~~models to better assess the influence of BB emissions.~~
