The characterization of long-range transported California biomass burning plumes: what can a multi-wavelength Mie-Raman-polarization-fluorescence lidar provide?

By Qiaoyun Hu et.al.

- Figure S1. UVAI (UV aerosol index) measured by OMPS instruments.
- Figure S2: Observations of CALIPSO on 07 September 2020.
- Figure S3: Observations of CALIPSO on 10 September 2020.

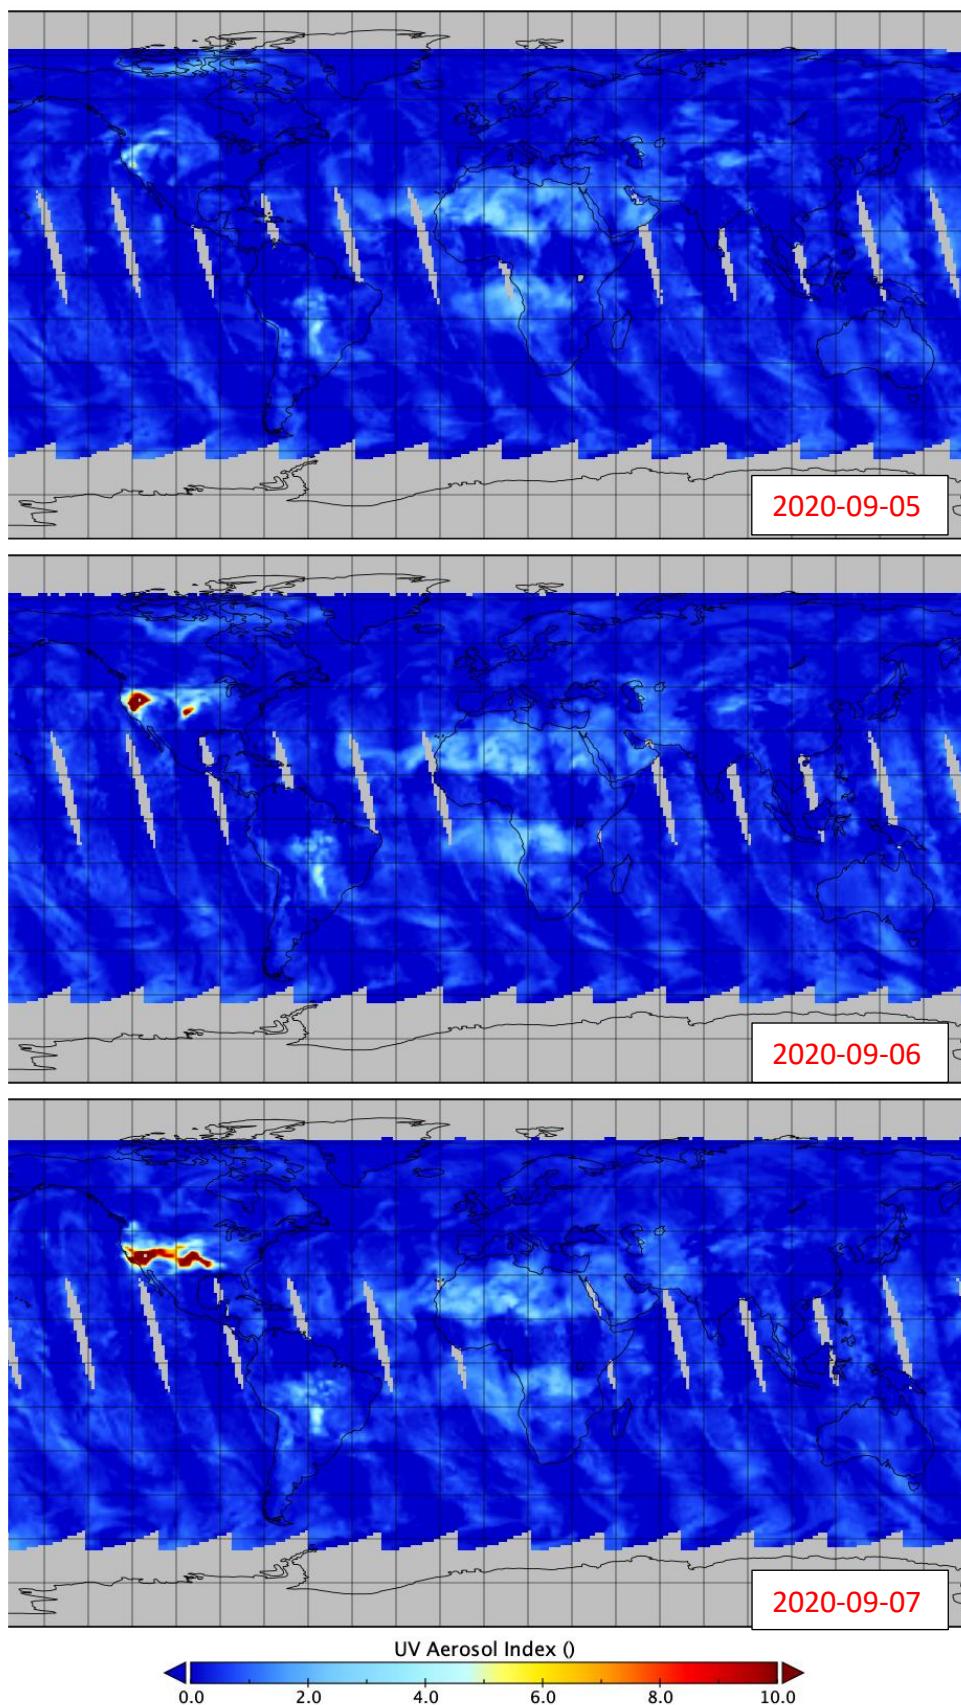

Figure S1: UVAAI (UV aerosol index) measured by OMPS instruments.

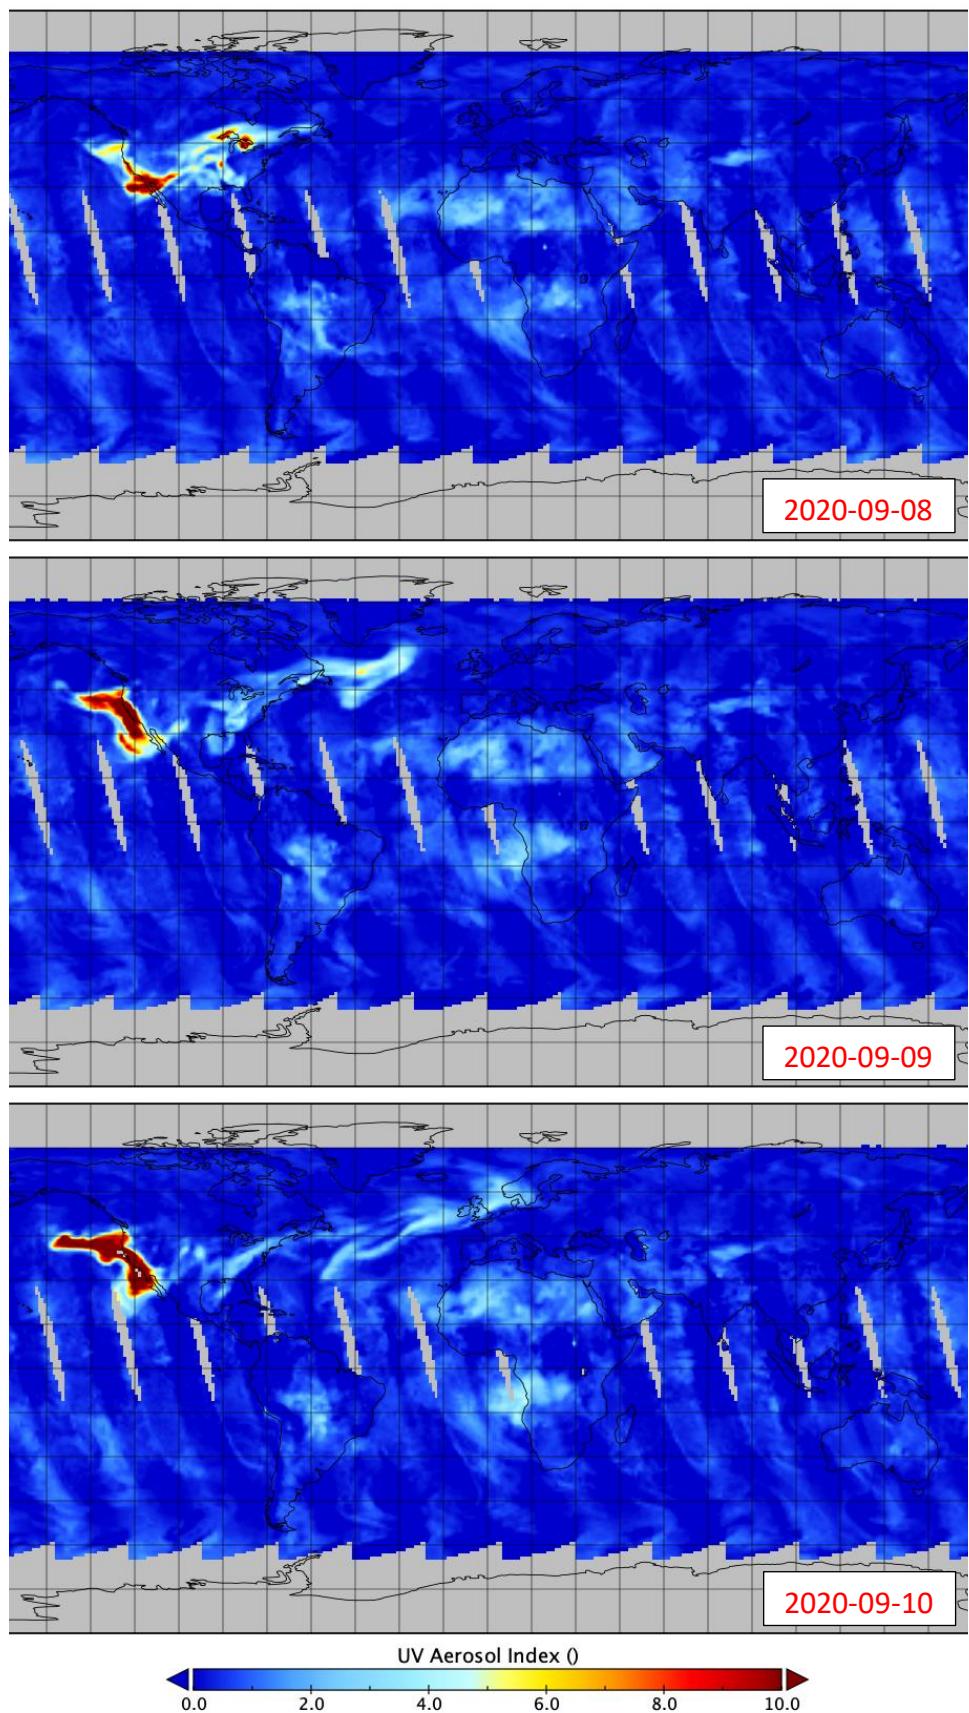

Figure S1: (Continued) UVAl (UV aerosol index) measured by OMPS instruments.

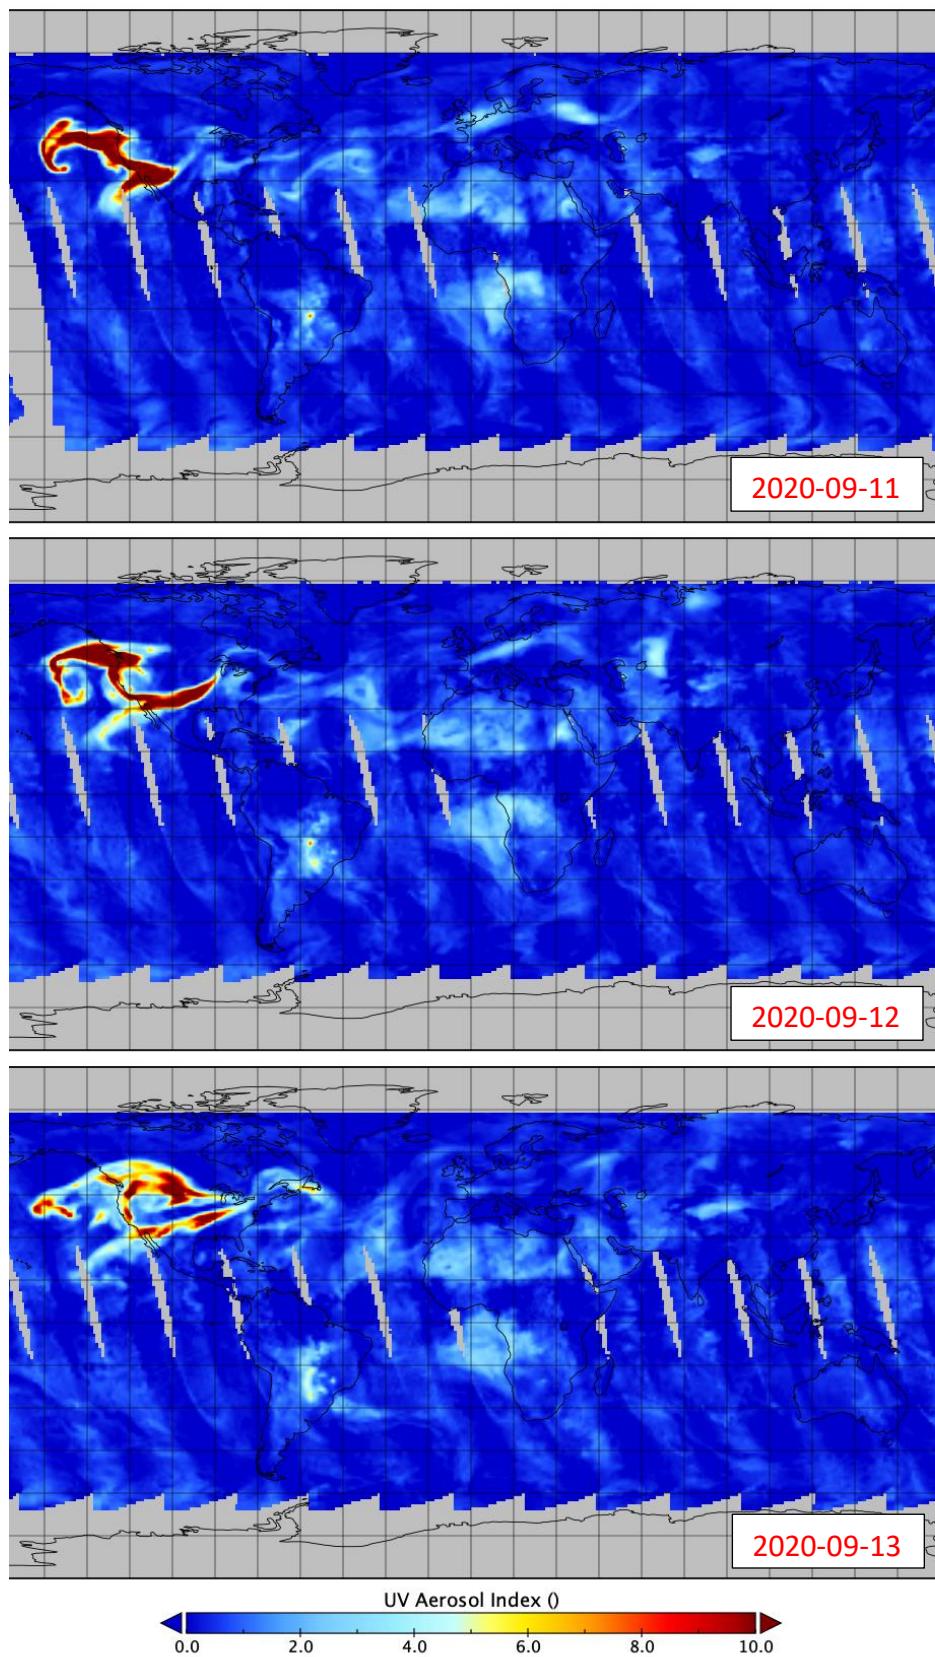

Figure S1: (Continued) UVAl (UV aerosol index) measured by OMPS instruments.

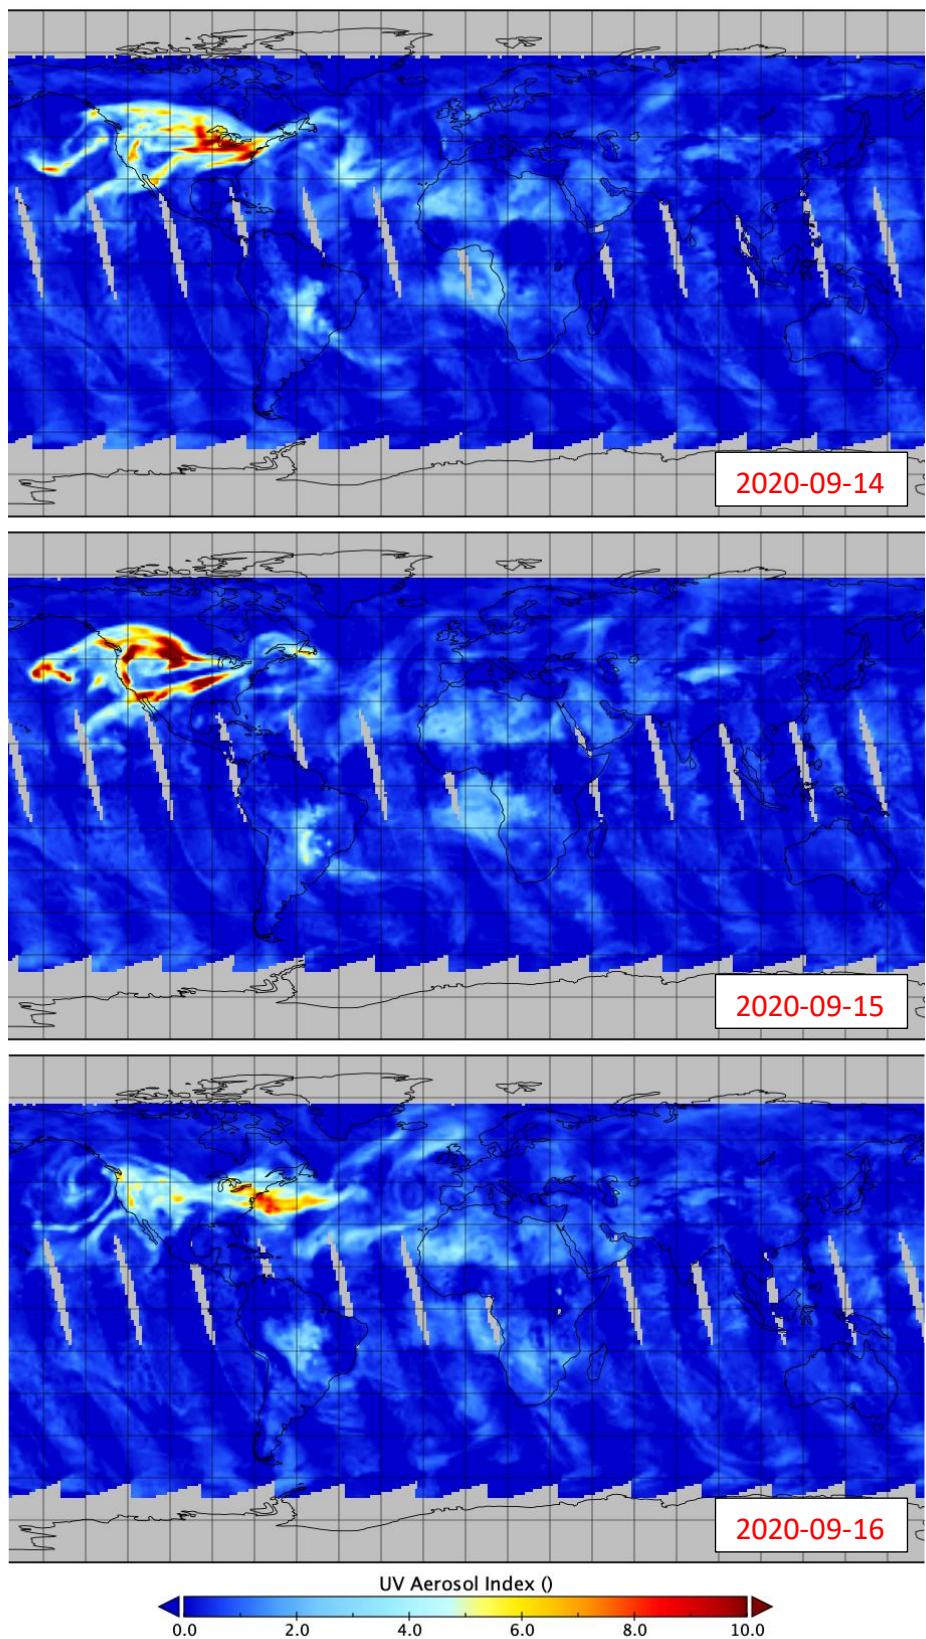

Figure S1: (Continued) UVAl (UV aerosol index) measured by OMPS instruments.

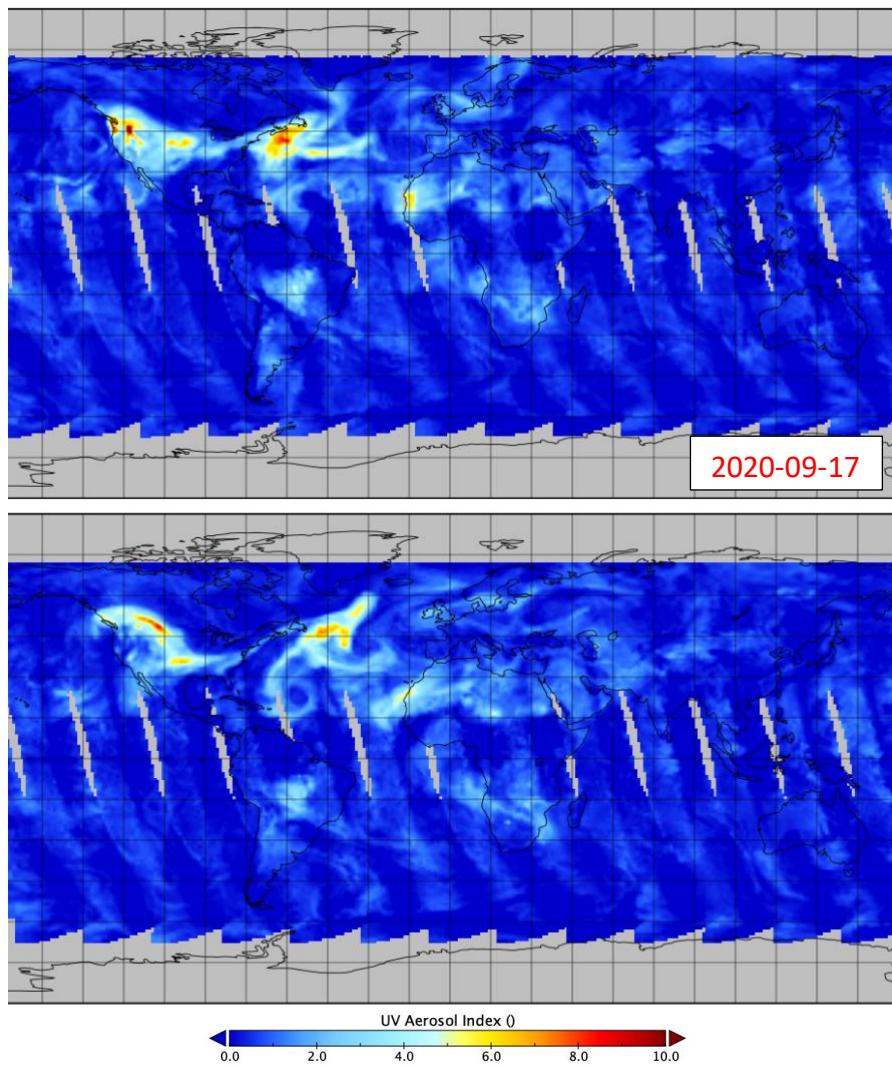

Figure S1: (Continued) UVAI (UV aerosol index) measured by OMPS instruments.

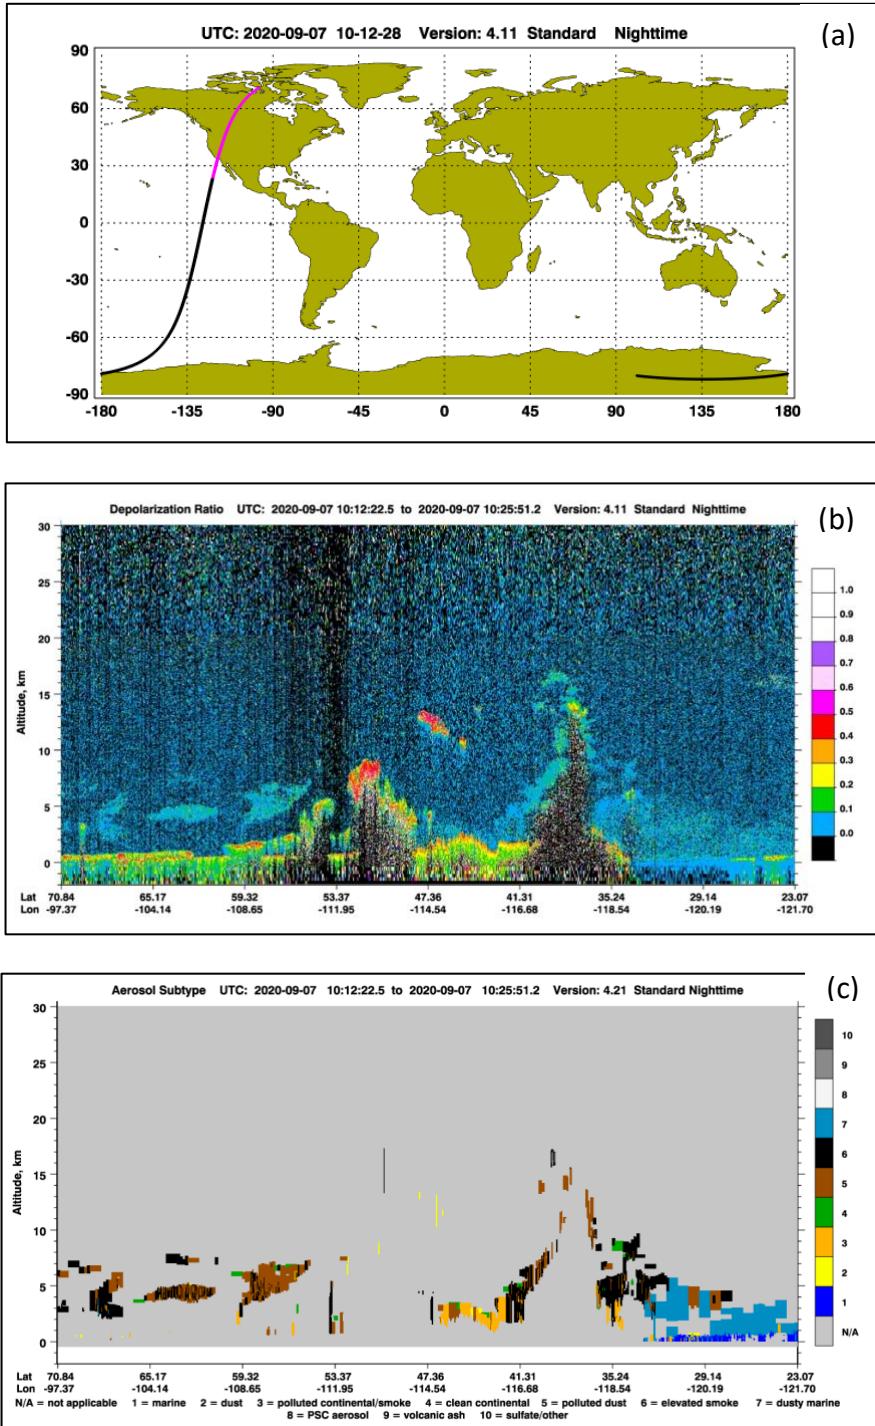

Figure S2: Observations of CALIPSO on 07 September 2020. (a) CALIPSO orbit track, (b) depolarization ratio at 532 nm, (c) aerosol subtype on 2020-09-07. A towering like pyro-cumulonimbus cloud with smoke from Creek fire was detected between (41.31N,116.68W) and (35.24N,118.54W)

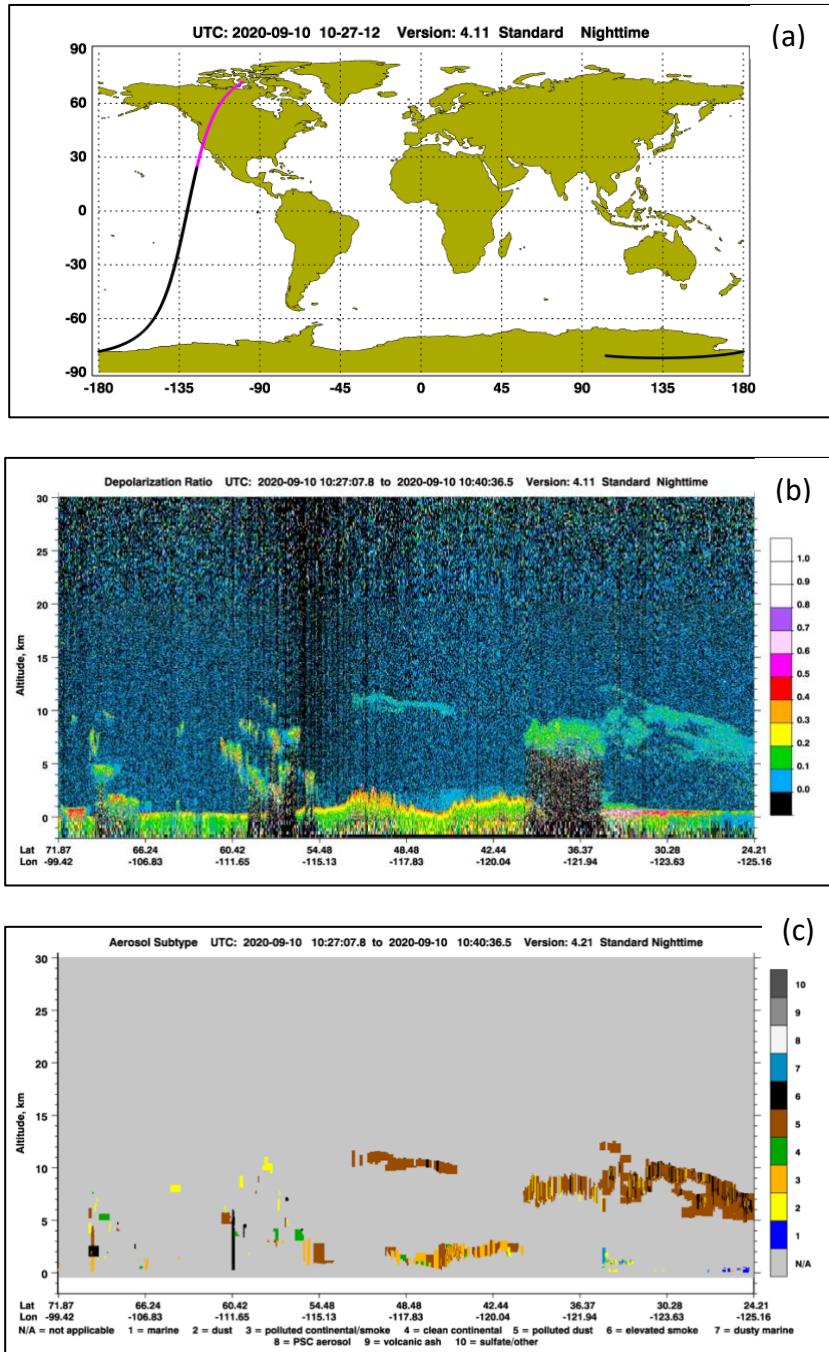

Figure S3: Observations of CALIPSO on 10 September 2020. (a) CALIPSO orbit track, (b) depolarization ratio at 532 nm, (c) aerosol subtype on 2020-09-10.
