14 **Abstract.** Emissions of ammonia (NH₃) to the atmosphere impact human health, climate, and ecosystems through their
15 critical contributions to secondary aerosol formation. Estimation of NH₃ emissions is associated with large uncertainties
16 because of inadequate knowledge about agricultural sources. Here, we use satellite observations from the Infrared
17 Atmospheric Sounding Interferometer (IASI) and simulations from the GEOS-Chem model to constrain global NH₃
18 emissions over the period of 2008-2018. We update the prior NH₃ emission fluxes with the ratio between biases in simulated
19 NH₃ concentrations and effective NH₃ lifetimes against the loss of the NH_x family. In contrast to about a factor of two
20 discrepancies between top-down and bottom-up emissions found in previous studies, our method results in a global land NH₃
21 emission of 78 (70-92) Tg a⁻¹, ~30 % higher than the bottom-up estimates. Regionally, we find that the bottom-up inventory
22 underestimates NH₃ emissions over South America and tropical Africa by 60-70 %, indicating under-representation of
23 agricultural sources in these regions. We find a good agreement within 10 % between bottom-up and top-down estimates
24 over the U.S., Europe, and eastern China. Our results also show significant increases in NH₃ emissions over India (13 %
25 decade⁻¹), tropical Africa (33 % decade⁻¹), and South America (18 % decade⁻¹) during our study period, consistent with the
26 intensifying agricultural activities in these regions in the past decade. We find that inclusion of sulfur dioxide (SO₂) column
27 observed by satellite is crucial for more accurate inference of NH₃ emission trends over important source regions such as
28 India and China where SO₂ emissions have changed rapidly in recent years.

29 **1 Introduction**

30 Emissions of ammonia (NH₃) to the atmosphere have critical implications for human health, climate, and ecosystems. As the
31 main alkaline gas, NH₃ reacts with acidic products from precursors such as nitrogen oxides (NO_x) and sulfur dioxide (SO₂)
32 to form fine particulate matter, which is a well-documented risk factor for human health, causing great welfare loss globally

33 ([Erisman 2021](#); [Gu et al., 2021](#)). Particulate matter also affects the Earth's radiative balance by directly scattering incoming
34 radiation ([Ma et al., 2012](#)) and indirectly as cloud condensation nuclei ([Höpfner et al., 2019](#)). Additionally, both gas-phase
35 ammonia (NH₃) and aerosol-phase ammonium (NH₄⁺) can deposit onto the surface of land and water through dry and wet
36 processes, and are associated with soil acidification ([Zhao et al., 2009](#)), ecosystem eutrophication ([Dirnböck et al., 2013](#)),
37 biodiversity loss ([Stevens et al., 2010](#)), and cropland nitrogen uptake ([Liu et al., 2013](#)).

38 NH₃ is emitted from a variety of anthropogenic and natural sources, including agriculture, industry, fossil fuel combustion,
39 biomass burning, natural soils, ocean, and wild animals ([Behera et al., 2013](#)). Among these, agricultural activities, mainly
40 livestock manure management and mineral fertilizer application, are the most important NH₃ sources, which account for ~70%
41 of the total NH₃ emissions globally ([Bouwman et al., 1997](#); [Sutton et al., 2013](#)). NH₃ emissions can be estimated with a
42 bottom-up approach based on information of emission activities and emission factors ([Hoesly et al., 2018](#); [Crippa et al.,](#)
43 [2021](#)). However, bottom-up estimates of NH₃ emissions are generally thought to be uncertain, relative to other pollutants that
44 are mainly from fossil fuel combustion sources (e.g., NO_x, CO). One of the challenges is that the intensity of agricultural
45 NH₃ emissions, emission factors, either from livestock or fertilizer, depends strongly on management and farming practices,
46 but this information is usually not widely available ([Zhang et al., 2017](#)). Furthermore, microbial activities that are
47 responsible for agricultural NH₃ emissions are highly variable and has a complex dependence on environmental conditions,
48 which is often inadequately captured by bottom-up approaches ([Behera et al., 2013](#); [Vira et al., 2021](#)). In many cases,
49 emission factors used in bottom-up modelling are based on local studies that are not representative for the diversity of
50 conditions and are not dependent on meteorological parameters.

51 Top-down analyses of atmospheric observations (e.g., NH₃ concentrations or NH₄⁺ depositional fluxes) provide an alternative
52 constraint on NH₃ emissions. For example, observations of NH₃ concentrations and NH₄⁺ deposition fluxes from surface
53 networks can be used to infer regional NH₃ emission fluxes (e.g., [Paulot et al., 2014](#)). However, surface sites are often sparse,
54 especially in developing continents such as Africa and South America, limiting our capability to constrain NH₃ emissions
55 globally. The advent of satellite observations makes it possible to investigate long-term spatially resolved NH₃ emissions
56 from national, continental, to global scales. Van Damme et al. ([2018](#)) reported large NH₃ point sources across the globe that
57 are detected by the Infrared Atmospheric Sounding Interferometer (IASI) instrument but missing in the bottom-up
58 inventories. Studies have also applied satellite data (e.g., IASI and Cross-track Infrared Sounder (CrIS)) to study NH₃
59 emissions from important source regions, including the U.S. ([Cao et al., 2020](#); [Chen et al., 2021b](#)), China ([Zhang et al.,](#)
60 [2018](#)), and Europe ([Marais et al., 2021](#); [van der Graaf et al., 2021](#)). These regional studies show 20 % to 50 % differences
61 between top-down and bottom-up estimates of NH₃ emissions.

62 Compared to regional analyses, long-term global analyses of NH₃ emissions based on satellite observations are relatively
63 scarce (e.g., [Evangelou et al., 2021](#)). This is partly because of the computational challenges arising from a full-fledged
64 inversion for a long period of time and over large spatial extents. In a recent study, Evangelou et al. ([2021](#)) proposed a fast
65 top-down method, in which NH₃ emissions are computed as the ratio between NH₃ column observations and NH₃ lifetime.
66 This method relies on NH₃ lifetime diagnosed from a chemical transport model (CTM) and assumes a local mass balance.

67 Their analysis found a global NH_3 emission of around 180 Tg a^{-1} , which is roughly triple the widely used bottom-up
68 estimates (e.g., 62 Tg a^{-1} by the Community Emission Data System, CEDS). This large upward adjustment, if true, would
69 have huge implications for global reactive nitrogen cycles and indicate that our current understanding of global NH_3
70 emissions is seriously flawed.

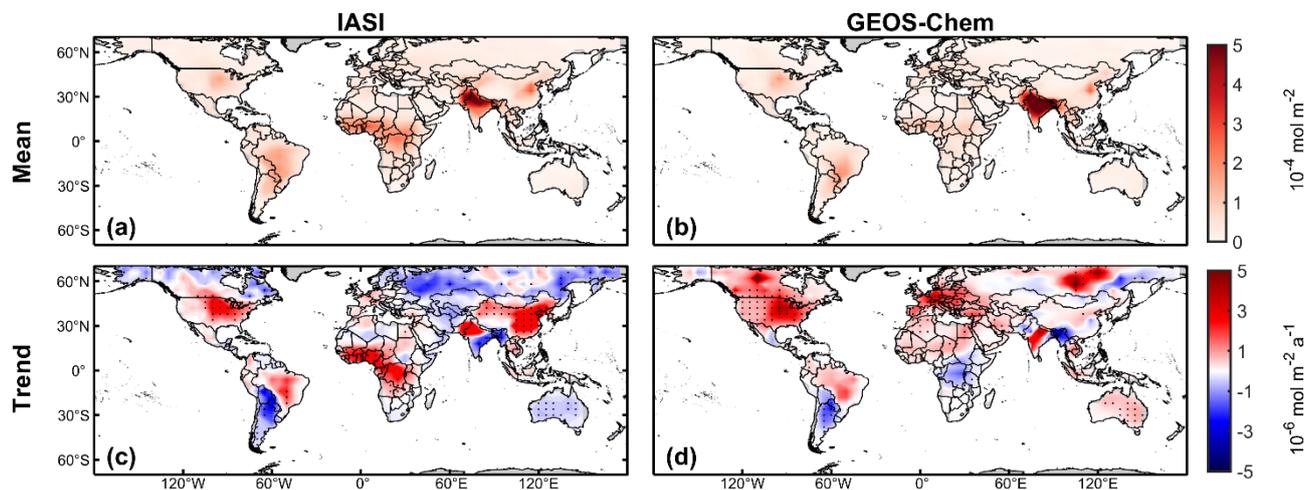

71 In this paper, we examine if the large discrepancy between the bottom-up and top-down estimates is due to the methodology.
72 We refine the fast top-down approach by improving NH_3 lifetime diagnosis and partially accounting for the transport
73 contributions. We develop a series of data filtering procedures to exclude results that are not sufficiently constrained by
74 observations or affected by large deviations from the assumption of the fast top-down method. We apply the updated method
75 to IASI observations to derive the global distribution of NH_3 emissions fluxes from 2008 to 2018, and examine the impact of
76 the improved method on global NH_3 emission inferences.

77 **2 Methods**

78 **2.1 IASI observations**

79 We use 2008-2018 reanalyzed daily NH_3 total column retrievals (ANNI- NH_3 -v3R) from the IASI on board Metop-A. The
80 IASI instrument measures the infrared radiation ($645\text{--}2760 \text{ cm}^{-1}$) from Earth's surface and the atmosphere with a circular 12
81 km footprint at nadir (Clerbaux et al., 2009; Van Damme et al., 2017). The retrieval algorithm calculates the hyperspectral
82 range index from IASI spectra measurements (Van Damme et al. 2014) and converts it to the NH_3 total column density via
83 an artificial neural network (Whitburn et al., 2016; Franco et al., 2018). The retrieval uses consistent meteorological data
84 from the ERA5 reanalysis, so it is suitable for the analyses of inter-annual variability and long-term trends (Hersbach et al.,
85 2020). The ANNI- NH_3 -v3R product, has been validated against in situ measurements and is shown to have a good regional
86 correlation (Guo et al., 2021; Van Damme et al., 2021). The dataset has been used in previous studies to estimate NH_3
87 emissions globally (e.g., Evangeliou et al., 2021) and regionally (e.g., Chen et al., 2021b; Marais et al., 2021).

88 Here we only use morning NH_3 data (around 9:30 local solar time) though IASI provides global coverage twice daily,
89 because of the better precision of morning observations resulting from favourable thermal contrast conditions (Clarisse et al.
90 2010). We filter out data with a cloud fraction greater than 10 % (Van Damme et al., 2018) and a skin temperature below
91 263 K (Van Damme et al., 2014). The skin temperature dataset is from ERA5 (Hersbach et al., 2020). To compare with
92 simulated NH_3 columns (see **Sect. 2.2**), we regrid and average monthly IASI NH_3 observations over land on the GEOS-
93 Chem $4^\circ \times 5^\circ$ grid (**Fig. 1a**). To reduce uncertainty from sparse sampling, we further exclude grid cells with the number of
94 successful retrievals less than 800 in a month. We also test the choices of the threshold for 400 and 1200 per month in the
95 sensitivity calculations (**Table 1**, line 5-6). This criterion affects mainly high latitudes during wintertime, where snow
96 surfaces make it unfavourable for infrared measurements (**Fig. S1**).

97

98

99 **Figure 1.** Spatial distribution of (a, c) IASI and (b, d) GEOS-Chem NH₃ column concentrations. (a, b) Mean and (c, d) linear trends within
 100 the 70°N-70°S during 2008-2018. Dots in (c) and (d) indicate that linear trends are significant at the 95% confidence levels. Linear trends
 101 are computed from the time series of annual averages.

102 2.2 GEOS-Chem simulations

103 We use the GEOS-Chem CTM v12.9.3 (10.5281/zenodo.3974569) to simulate global NH₃ concentrations. The GEOS-Chem
 104 model, driven by the MERRA-2 reanalyzed meteorology (Gelaro et al., 2017), simulates the tropospheric ozone-NO_x-
 105 VOCs-aerosol chemistry at 4° × 5° resolution with 47 vertical layers (30 layers in the troposphere) (Bey et al., 2001; Park et
 106 al., 2004). The thermodynamic equilibrium between gas phase NH₃ and aerosol phase NH₄⁺ is explicitly simulated by the
 107 ISORROPIA-II module in GEOS-Chem (Fountoukis & Nenes, 2007). The model also simulates the wet and dry deposition
 108 of NH₃ and NH₄⁺, the terminal sinks of atmospheric NH_x (≡ NH₃ + NH₄⁺). Dry deposition is represented with a resistances-
 109 in-series scheme (Wesely, 2007) and wet deposition includes scavenging in convective updrafts and in- and below-cloud
 110 scavenging from large-scale precipitation (Wang et al., 2011; Amos et al., 2012). Anthropogenic emissions of simulated
 111 chemicals including those of NH₃ are taken from a global emission inventory CEDS (Hoesly et al., 2018), overridden by
 112 regional inventories in Canada (Air Pollutant Emission Inventory, APEI), the United States (2011 National Emissions
 113 Inventory, NEI-2011), Asia (MIX-Asia v1.1) (Li et al., 2017), and Africa (DICE-Africa) (Eloise Marais and Christine
 114 Wiedinmyer, 2016). Such compiled anthropogenic emissions only include incomplete information on inter-annual trends
 115 because inventories are not all available throughout the whole period. Anthropogenic emissions are essentially invariant after
 116 2013 in our setup (Fig. S2). The general lack of trends in SO₂ emissions in the simulation, if not accounted for, may cause
 117 biases in inferred trends over regions such as India and China where SO₂ emissions have changed rapidly (Sun et al., 2018;
 118 Qu et al., 2019; Chen et al., 2021a). Fire emissions are from Global Fire Emissions Database (GFED4) (van der Werf et al.,
 119 2017), and biogenic VOC emissions are from the Model of Emissions of Gases and Aerosols from Nature (MEGAN)
 120 (Guenther et al., 2012). Temporal (seasonal and inter-annual) variations in fire and biogenic emissions are resolved by the
 121 inventories. Hereafter, we refer to NH₃ prior bottom-up emissions from this set of inventories as BUE1. For comparison, we

122 also use another set of bottom-up inventories which consist of EDGARv5.0 for anthropogenic emissions
 123 (<https://data.jrc.ec.europa.eu/collection/edgar>, last access: 8 March 2022, [Crippa et al., 2020](#)), GFAS for fire emissions
 124 (CAMS, <https://apps.ecmwf.int/datasets/data/cams-gfas/>, last access: 8 March 2022) (minor natural emissions are the same
 125 as BUE1), which we denote as BUE2.

126 The GEOS-Chem simulation is conducted from 2008 to 2018 with an additional 1-month spin-up starting from December
 127 2007. We sample the simulated NH_3 and NH_4^+ concentration fields between 9:00 to 10:00 local solar time, approximately the
 128 IASI morning overpass time. To compare with the IASI NH_3 columns, we integrate the vertical profiles of simulated NH_3
 129 concentrations by layer thickness. We note that the ANNI- NH_3 -v3R retrieval does not provide averaging kernels ([Whitburn](#)
 130 [et al., 2016](#); [Van Damme et al., 2021](#)). However, [Van Damme et al. \(2018\)](#) reported the uncertainty in different vertical
 131 profiles of individual NH_3 measurements to be $2\% \pm 24\%$ (global average). Besides, we also archive depositional and
 132 transport rates for NH_3 and NH_4^+ , which are used in emission fluxes estimation. In addition, we perform GEOS-Chem
 133 simulations in selected years (2008, 2013, 2018) to examine the validation and consistency of our top-down NH_3 emission
 134 estimates with the ground-based measurements and IASI observations.

135 2.3 NH_3 emission fluxes estimation

136 We compute NH_3 fluxes (\hat{E}_{NH_3} , in molecules $\text{m}^{-2} \text{s}^{-1}$) in land grid cells for individual months from 2008 to 2018. We update
 137 the prior model emission fluxes ($E_{\text{NH}_3,\text{mod}}$, in molecules $\text{m}^{-2} \text{s}^{-1}$) with a correction term positively proportional to the
 138 difference of observed ($C_{\text{NH}_3,\text{obs}}$, in molecules m^{-2}) and simulated ($C_{\text{NH}_3,\text{mod}}$, in molecules m^{-2}) monthly averaged NH_3 total
 139 column densities and inversely proportional to the lifetime of NH_3 ($\tau_{\text{NH}_3,\text{mod}}$, in s):

$$140 \quad \hat{E}_{\text{NH}_3} = E_{\text{NH}_3,\text{mod}} + \frac{C_{\text{NH}_3,\text{obs}} - C_{\text{NH}_3,\text{mod}}}{\tau_{\text{NH}_3,\text{mod}}}, \quad (1)$$

141 where $\tau_{\text{NH}_3,\text{mod}}$ is computed as the ratio of the simulated NH_3 column and the sum of simulated loss rate of the NH_x family
 142 ($\text{NH}_x \equiv \text{NH}_3 + \text{NH}_4^+$) through the dry and wet depositions of NH_3 ($D_{\text{NH}_3,\text{mod}}$, in molecules $\text{m}^{-2} \text{s}^{-1}$) and NH_4^+ ($D_{\text{NH}_4^+,\text{mod}}$, in
 143 molecules $\text{m}^{-2} \text{s}^{-1}$):

$$144 \quad \tau_{\text{NH}_3,\text{mod}} = \frac{C_{\text{NH}_3,\text{mod}}}{D_{\text{NH}_3,\text{mod}} + D_{\text{NH}_4^+,\text{mod}}}. \quad (2)$$

145 Here we calculate the lifetime of NH_3 with the loss of the NH_x family rather than that of NH_3 , because of the fast
 146 thermodynamic equilibrium between gas-phase NH_3 and aerosol/aqueous-phase NH_4^+ , which implies that the conversion
 147 from NH_3 to NH_4^+ is not a terminal loss for NH_3 from the atmosphere. The NH_3 lifetime may be underestimated over source
 148 regions and overestimated over remote regions, if NH_3 to NH_4^+ conversions are treated as a terminal loss as in [Evangelou et](#)
 149 [al. \(2021\)](#) rather than a partition within a chemical family (NH_x) as in **Eq. (2)**.

150 In addition, our method linearizes the column-emission relationship at prior emissions as opposed to zero emissions in the
 151 previous method (e.g., [Evangelou et al., 2021](#)). Here, the baseline NH_3 column ($C_{\text{NH}_3,\text{mod}}$) simulated by the GEOS-Chem

152 model explicitly accounts for the non-local contribution of transport, while the correction to prior emissions is done only
 153 locally, that is, the difference between $C_{\text{NH}_3,\text{obs}}$ and $C_{\text{NH}_3,\text{mod}}$ is attributed only to errors in local emissions without
 154 accounting for the sensitivity to emissions from other grid cells. This hybrid approach can partially include the non-local
 155 contribution from transport but still keeps the computation tractable for a long-term study such as this study, striking a trade-
 156 off between the computational efficiency of a local mass balance method (e.g., [Van Damme et al., 2018](#); [Evangelidou et al.,](#)
 157 [2021](#)) and the accuracy of a full-fledged inversion, such as the 4D-Var method (e.g., [Cao et al., 2020](#); [Chen et al., 2021b](#)).
 158 The errors arising from local correction of NH_3 emissions are expected to be small in most cases, because the NH_3 lifetime is
 159 short relative to a typical transport time across a $4^\circ \times 5^\circ$ grid cell on which emissions are estimated. To identify cases when
 160 this error is not negligible, we apply a monthly NH_x budget analysis based on the GEOS-Chem simulation and exclude grid
 161 cells from our analysis where transport dominates over local prior emissions or depositions in the monthly NH_x budget
 162 (Transport/Emission>1 or Transport/Deposition>1) (**Fig. S3**).

163 Because rapid changes in SO_2 emissions in eastern China and India, particularly after 2012, are not captured by our prior
 164 simulation (**Fig. S2**), the estimation of NH_3 emission trends using **Eq. (1)** may be biased over these regions. To address this
 165 issue, we further modify **Eq. (1)** to include observed trends in SO_2 column concentrations:

$$166 \quad \hat{E}_{\text{NH}_3,\text{SO}_2\text{-correct}} = E_{\text{NH}_3,\text{mod}} + \frac{C_{\text{NH}_3,\text{obs}} - C_{\text{NH}_3,\text{mod}} + 2\omega C_{\text{SO}_4^{2-},\text{mod}}}{\tau_{\text{NH}_3,\text{mod}}}, \quad (3)$$

167 where ω (%) is the fractional changes of average SO_2 columns relative to the baseline year (i.e., 2012) over China or India
 168 and $C_{\text{SO}_4^{2-},\text{mod}}$ (molecules $\text{m}^{-2} \text{s}^{-1}$) is the simulated column densities of aerosol sulfate. Here, we specify a linear trend of -5 %
 169 a^{-1} for eastern China and 5 % a^{-1} for India between 2012 and 2018, based on values derived from the ozone monitoring
 170 instrument (OMI) and Ozone Mapping and Profiler Suite (OMPS) observations ([Wang and Wang, 2020](#); [Liu et al., 2018](#)).
 171 We also test the impact of the uncertainty in ω on trend inferences over China and India. The factor 2 accounts for the fact
 172 that two molecules of NH_3 are required to neutralize one molecule of H_2SO_4 . **Eq. (3)** only applies when NH_3 is in excess, a
 173 condition usually met in eastern China and India but not necessarily elsewhere ([Lachatre et al., 2019](#); [Acharja et al., 2022](#)).
 174 Therefore, we only apply **Eq. (3)** to eastern China and India to understand the impact of changing SO_2 emissions on the
 175 inference of NH_3 emission trends. To use SO_2 observations systematically in NH_3 emission estimations requires further
 176 investigations.

177 **2.4 Uncertainty and sensitivity analysis**

178 We perform a series of perturbation and sensitivity experiments to assess the uncertainty of our estimates (**Table 1**. We
 179 perturb $C_{\text{NH}_3,\text{mod}}$ and $\tau_{\text{NH}_3,\text{mod}}$ in **Eq. (1)**. The perturbations to $\tau_{\text{NH}_3,\text{mod}}$ are set to be 50 % and 200 % (**Table 1**, Line 1-2).
 180 The perturbation to $C_{\text{NH}_3,\text{mod}}$ is set to be the standard deviation of monthly mean column concentrations ($\sigma_{C,\text{obs}}$) (**Table 1**,
 181 Line 3-4), which is given by:

182

$$\sigma_{C,obs} = \sqrt{\frac{\sum_{i=1}^{i=n} (\sigma_i \times \Omega_i)^2}{n-1}}, \quad (4)$$

183 where Ω_i (in mol m⁻²) is the i^{th} NH₃ column measurement out of a total number of n observations in a grid cell during a
 184 month and σ_i is the relative error. We then use $\Omega \pm \sigma_{C,obs}$ to evaluate the effect of measurement errors in emission estimates
 185 (**Table 1**, Line 3-4). We compute results with alternative data filtering parameters (**Table 1**, Line 5-8), including the
 186 thresholds to exclude grid cells when the number of observations is too small (**Table 1**, line 5-6) and the local mass balance
 187 assumption is potentially invalid (**Table 1**, Line 7-8). We also test if our trend inferences over China and India using Eq. (3)
 188 is sensitive to uncertainty in observed trends in SO₂ concentrations (ω).

189 **Table 1.** Uncertainty and sensitivity analyses of top-down NH₃ emissions. Annual averaged NH₃ emissions are summed over global land
 190 areas for 2008–2018.

	Parameter perturbed	Average emission (Tg a ⁻¹)
0	None ^a (TDE)	78
1	Halved NH ₃ lifetime ^b	92
2	Doubled NH ₃ lifetime ^c	70
3	Upper IASI column error	83
4	Lower IASI column error	72
5	Number of retrievals > 400 ^d	81
6	Number of retrievals > 1200 ^e	74
7	Transport/Emission < 0.2 ^f	72
8	Transport/Emission < 5 ^g	84

191 ^aExcluding a grid cell if retrieval number is less than 800 during a month, or transport dominates over emissions or
 192 depositions in the simulated monthly NH₃ budget.

193 ^{b-c}The lifetime is 50 % and 200 % of values from Eq. (1), respectively.

194 ^{d-e}Monthly retrieval number threshold for including a grid cell is set to be 400 and 1200, respectively.

195 ^{f-g}Local budget ratio the threshold for including a grid cell is set to be 0.2 and 5, respectively.

196 3 Results and discussion

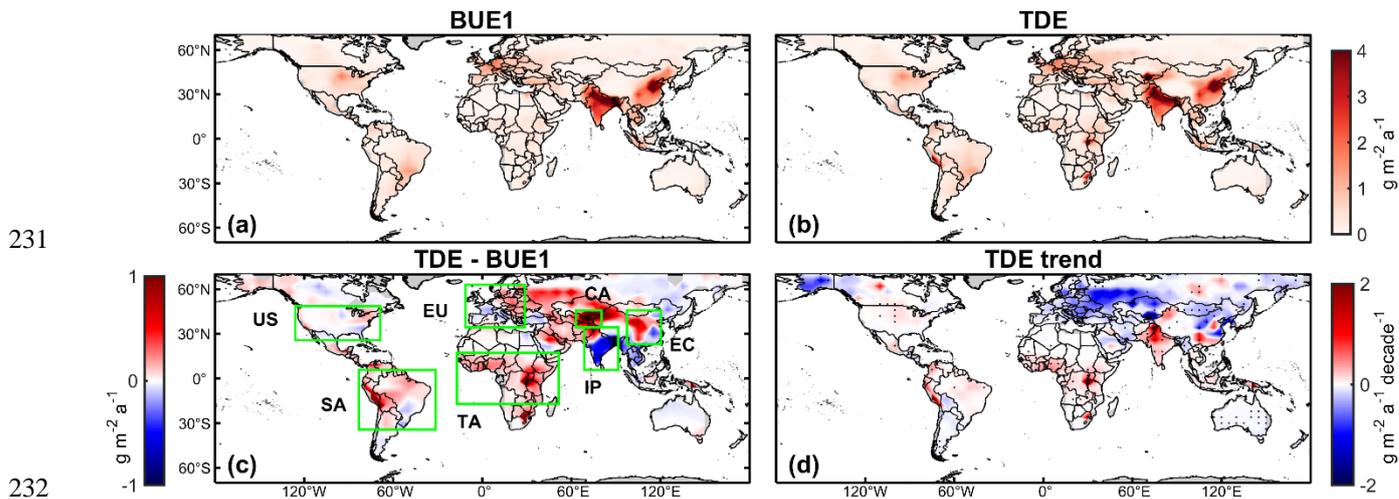

197 3.1 Observed and simulated NH₃ concentrations

198 **Fig. 1a and 1b** plot observed and simulated NH₃ total column concentrations averaged over 2008-2018. The GEOS-Chem
 199 simulation generally reproduces the global distribution of NH₃ concentrations observed by the IASI instrument. Good
 200 agreements (i.e., difference < 10 %) are found in the U.S., Europe, and southern South America. Meanwhile, the GEOS-

201 Chem model underestimates NH_3 concentrations in eastern China, northern South America, and tropical Africa by 20-120 %,
202 and overestimates in southern India by around 50 %, indicating biases in NH_3 emissions over these regions.
203 **Fig. 1c and 1d** show 2008-2018 linear trends in NH_3 column concentrations derived from the IASI observations and the
204 GEOS-Chem simulations. The linear trends are computed based on the time series of annual averages. The IASI trends
205 shown in Fig. 1c are in general consistent with a recent analysis by Van Damme et al. (2021). IASI observes a positive NH_3
206 concentration trend of $2.9 \% \text{ a}^{-1}$ over the U.S., and this trend is well captured by GEOS-Chem. Similarly, the observation and
207 the simulation agree on a dipole pattern in South America (i.e., positive trend in Brazil and negative trend in Argentina).
208 Because anthropogenic emissions over this region are set to be invariant in our simulation (**Fig. S2**), this agreement suggests
209 that these trends are due to meteorological conditions and/or fire emissions, rather than changes in anthropogenic emissions.
210 The satellite also observes significant positive trends in NH_3 concentrations over China ($5.2 \% \text{ a}^{-1}$) and tropical Africa ($2.0 \% \text{ a}^{-1}$),
211 but these trends are not reproduced in the simulation ($0.3 \% \text{ a}^{-1}$ for China and $0.2 \% \text{ a}^{-1}$ for tropical Africa). These
212 simulation-observation differences can not only reflect discrepancies in the trends of anthropogenic NH_3 emissions, but also
213 be attributed to uncaptured changes in SO_2 and/or NO_x emissions in these regions. We also find that a positive NH_3
214 concentration trend over Europe appears in the simulation ($3.0 \% \text{ a}^{-1}$) but is much weaker ($1.0 \% \text{ a}^{-1}$) in the observation,
215 suggesting decreasing emissions after 2013. Satellite data shows positive NH_3 concentration trends in north-western India
216 but negative trends in in south-eastern India which are not reproduced by the simulation, though these trends over India are
217 mostly insignificant (at the 95 % confidence level) except for a few grid cells in the Southeast. Strong GEOS-Chem trends in
218 eastern Canada and Siberia result from large wildfires that occurred in the latter part of the study period. IASI trends in
219 northern boreal regions are less robust because of noisy and sparse measurements over high latitudes (**Fig. S1** and **Fig. S3**)

220 **3.2 NH_3 emissions inferred from IASI observations**

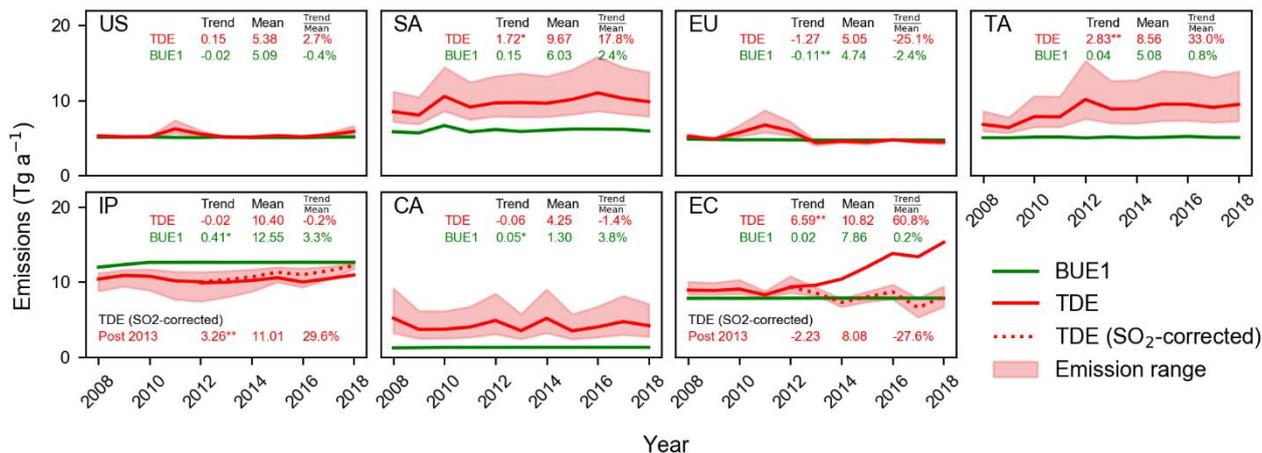

221 **Fig. 2** shows the spatial distributions of NH_3 emission fluxes and their 2008–2018 linear trends inferred from IASI
222 observations using the method described in **Sect. 2.3**. **Fig. 3** plots annual time series aggregated for seven selected regions.
223 The top-down emission (TDE) estimates suggest upward adjustments in NH_3 emissions over South America (SA) by 62 %,
224 tropical Africa (TA) by 69 %, and Central Asia (CA) by 327 %, relative to the prior inventory (BUE1), but downward
225 adjustments in NH_3 emissions by 14 % in India Peninsula (IP) and by 33 % in Canada. After accounting for the contributions
226 from natural emissions including fires, we find that most of these biases in NH_3 emissions can be attributed to anthropogenic
227 sources, except for Canada where the underestimation appears to relate to fire emissions. This result reflects a general
228 inadequate representation of agricultural and industrial emissions from developing continents in current global emission
229 inventories. The TDE finds good agreements with the BUE1 (difference within 10 %) over the U.S., Europe (EU), eastern
230 China (EC) and Australia.

233 **Figure 2.** Spatial distribution of NH_3 emission fluxes during 2008-2018. (a) Bottom-up emissions (BUE1), (b) top-down emissions (TDE)
 234 inferred from IASI observations, (c) difference between TDE and BUE1 estimates and (d) emission trends derived from TDE estimates.
 235 Green boxes denote seven regions analyzed in Sect. 3.2. Top-down emission fluxes are computed with Eq. (1) except for IP and EC where
 236 Eq. (3) is applied. Linear trends are computed from the time series of annual averages. Dots in (d) represent significant linear trends at the
 237 95 % confidence level.

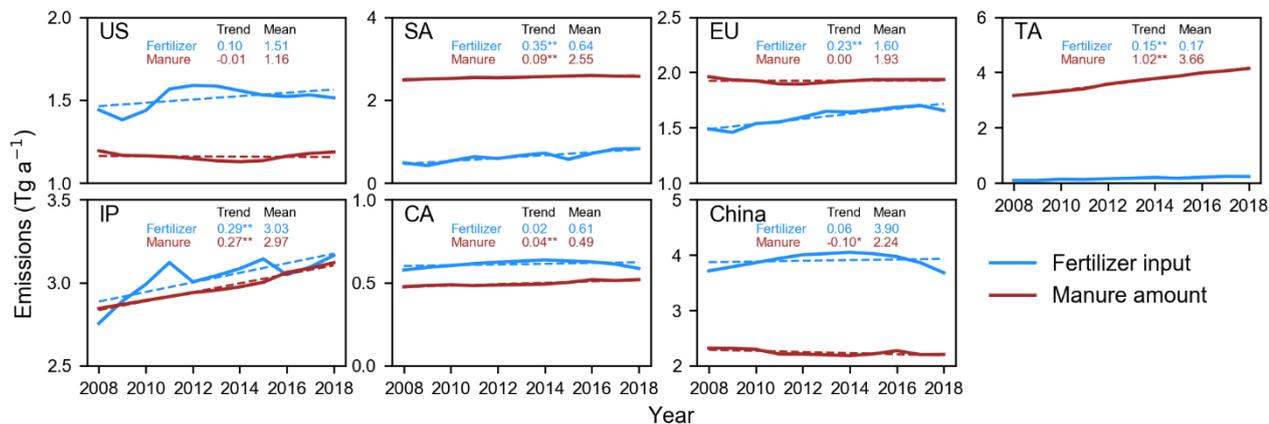

238 In addition to the adjustments in average emissions, the TDE also detects changes in NH_3 emissions during the period of
 239 2008-2018, as expressed in linear trends computed from annual time series. We find significant positive emission trends in
 240 SA ($1.7 \text{ Tg a}^{-1} \text{ decade}^{-1}$ or $18 \% \text{ decade}^{-1}$) and TA ($2.8 \text{ Tg a}^{-1} \text{ decade}^{-1}$ or $33 \% \text{ decade}^{-1}$) (**Fig. 3**). The large positive trends in
 241 TA are found around Lake Natron, consistent with Clarisse et al. (2019) (Fig. 2d). These increases in NH_3 emissions are
 242 concurrent with intensifying agricultural activities in these regions (Warner et al., 2017; E. Hickman et al., 2020), except for
 243 a 2010 peak over SA, which coincides with fires in savanna and evergreen forests there (Chen et al., 2013). Comparison with
 244 data from the Food and Agriculture Organization of the United Nations (FAO) (<http://www.fao.org/faostat>, last access: 7
 245 May 2022) suggests that the increase in SA is driven primarily by growing application of synthetic fertilizer ($55 \% \text{ decade}^{-1}$),
 246 whereas the increase in TA is consistent with increasing manure amount ($28 \% \text{ decade}^{-1}$) from a growing livestock
 247 population (E. Hickman et al., 2021) (**Fig. 4**).

248 Our results infer large but variable trends over northern high latitudes (e.g., negative trends in Alaska, central Russia, and
 249 eastern Europe, but positive trends in Canada) (**Fig. 2d**). Because of large uncertainties associated with high-latitude
 250 observations and emission optimization, these trends are less robust but can be partly attributed to variations in fire activities.
 251 Decreases in Russia and eastern Europe are related to wildfire of boreal forests in early part of the study period (2008-2011)
 252 (Keywood et al., 2012; Warner et al., 2017), while emission increases in Canada is due to wildfire in the late part of the
 253 period (2013-2016 and 2017) (Pavlovic et al., 2016), as also shown in the prior fire inventory (GFED4) (**Fig. S4**). We also
 254 infer negative trends ($-43 \% \text{ decade}^{-1}$) in Australia, which are statistically significant, but the absolute magnitude of these
 255 trends is small ($-0.03 \text{ g m}^{-2} \text{ a}^{-1} \text{ decade}^{-1}$ in **Fig. 2d**). The TDE estimation does not find significant trends in NH_3 total
 256 emissions over the US and Central Asia.

257

258 **Figure 3.** Annual NH₃ emissions for seven selected regions during 2008-2018. Shadings represent the upper and lower bounds derived
 259 from uncertainty analyses (see Sect. 2.4). Average annual emissions (Tg a⁻¹), absolute linear trends (Tg a⁻¹ decade⁻¹) and relative trends (%
 260 decade⁻¹) for 2008-2018 are inset. The asterisk symbols '**' and '***' represent that linear trends are significant at the 95 % and 99 %
 261 confidence level, respectively. Red dashed lines represent top-down NH₃ emission estimates over IP and EC during 2013-2018, based on
 262 Eq. (3) that accounts for observed trends of SO₂ (denoted as "SO₂-corrected"). Statistics for this estimate are also inset. The prior
 263 inventory (BUE1) implemented in our simulation only partially account for inter-annual changes from bottom-up information (i.e., Fig. 4).

264

265 **Figure 4.** Synthetic fertilizer and livestock manure amount based on FAO reports (<http://www.fao.org/faostat>) during 2008-2018. To
 266 roughly compare the contribution from the two sectors, we convert FAO reported statistics to NH₃ emissions (Tg a⁻¹) by applying fixed
 267 emission factors of 13 % for manure N contents (Ma et al., 2020) and 17 % for synthetic fertilizer N contents (Riddick et al., 2016). Values
 268 of means (Tg a⁻¹) and linear trends (Tg a⁻¹ decade⁻¹) are inset. Scales differ between panels.

269 3.3 Impact of changing SO₂ emissions on NH₃ emission trends over eastern China and India

270 Based on NH₃ column measurements (Eq. (1)), we also find a decadal increase of 61 % decade⁻¹ (6.6 Tg a⁻¹ decade⁻¹) in NH₃
 271 emissions over eastern China (Fig. 3). This increase is especially large after 2013 and is driven mainly by increases of IASI
 272 NH₃ column concentration in eastern China (Fig. 1c). This large post-2013 increase is inconsistent with flat or even
 273 declining fertilizer input and manure amount (Fig. 4). On the other hand, we find no appreciable emission trend in IP (Fig. 3),

274 which appears to agree with relatively stable IASI NH₃ concentrations over the period (**Fig. 1c**) but is not supported by
275 increases in fertilizer applications and manure amount shown in the FAO report (**Fig. 4**).

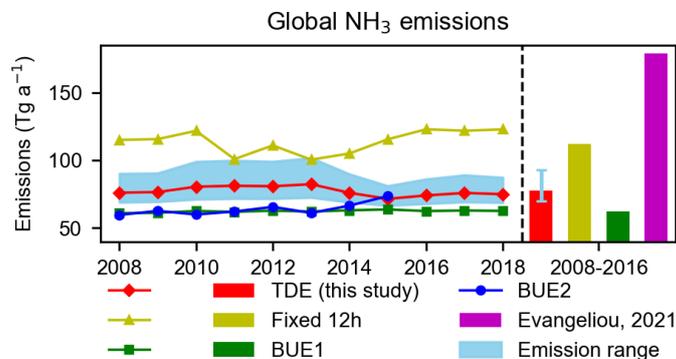

276 An assumption underlying **Eq. (1)** is that the model simulation captures the partition between gas-phase NH₃ and aerosol-
277 phase NH₄⁺. In addition to alkaline NH₃, the partition is also determined by the abundance of acids (e.g., H₂SO₄ and HNO₃).
278 Inaccurate emissions of their precursors (e.g., SO₂ and NO₂) in the model simulation, in particular over regions with
279 excessive NH₃, can lead to biases in simulating the NH₃-NH₄⁺ partition. It is well known that SO₂ emissions in China have
280 decreased rapidly after 2013 because of stringent air pollution control measures (Sun et al., 2018; Zhai et al., 2021), while
281 SO₂ emissions from India have been increasing (Qu et al., 2019). But these regional trends are not captured in our prior
282 simulation because our simulation does not have annual-varying emission inventories for these regions (**Fig. S2**).

283 We find that the discrepancies between top-down (**Eq. 1**) and bottom-up estimates of emission trends over EC and IP can be
284 largely reconciled by including observed SO₂ column concentrations in the top-down calculation (**Eq. (3)**). By accounting
285 for OMI and OMPS observed SO₂ trends (Wang and Wang, 2020), we derive an overall decreasing trend in NH₃ emissions
286 in EC between 2013 and 2018 (-2.2 Tg a⁻¹ decade⁻¹, -28 % decade⁻¹). This result suggests that observed increases in NH₃
287 columns over China are largely explained by decreases in SO₂ emissions (**Fig. 1** and **Fig. 3**), consistent with previous studies
288 (Fu et al., 2017; Liu et al., 2018; Lachatre et al., 2019; Chen et al., 2021a). Bottom-up inventories (e.g., MEIC v1.3, EDGAR
289 v5.0) also report stable or declining NH₃ emissions from China during the period (Li et al., 2017; Crippa et al., 2020).
290 Meanwhile, the revised method (**Eq. (3)**) finds a positive post-2013 trend (3.3 Tg a⁻¹ decade⁻¹, 30 % yr⁻¹) in NH₃ emissions
291 over India. Compared with our original estimate using **Eq. (1)**, NH₃ emission trends derived with **Eq. (3)** (i.e., decrease in
292 China and increase in India after 2013) is more consistent with the bottom-up information of fertilizer input and manure
293 management (**Fig. 4**). This result demonstrates the potential of assimilating both NH₃ and SO₂ satellite observations in
294 constraining NH₃ emissions, which should be further explored in the future.

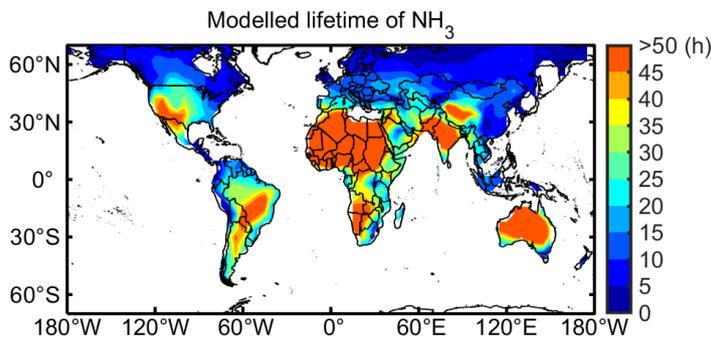

295 **3.4 Global total NH₃ emissions**

296 Integrating over land areas globally, our IASI-based TDE estimates of NH₃ is 78 (70-92) Tg a⁻¹ (range of estimates from
297 uncertainty analysis, see **Table 1**) (**Fig. 5**). This result is about 20-40 % higher than bottom-up inventories (BUE1, 62 Tg a⁻¹
298 and BUE2, 56 Tg a⁻¹). In contrast, a previous study by Evangeliou et al. (2021) also based on the IASI data estimated a much
299 higher global NH₃ emission of 180 Tg a⁻¹ (**Fig. 5**). One cause of the difference between the two IASI-based estimates is in
300 diagnosis of NH₃ lifetime from CTM. Evangeliou et al. (2021) treats conversion from NH₃ to NH₄⁺ as a terminal loss and
301 diagnoses NH₃ lifetime averaged 11.6 ± 0.6 h globally from a CTM, which is close to a constant NH₃ lifetime (12 h)
302 assumed in Van Damme et al. (2018). In this study, we account for the fact that fast thermodynamic equilibrium can
303 establish between NH₃ and NH₄⁺ so that NH₃ can only be terminally lost through the deposition of the NH_x family (**Eq. (2)**),
304 which yields a global averaged NH₃ lifetime of 21.2 ± 3.8 h (**Fig. 6**). This longer NH₃ lifetime implies a higher sensitivity of
305 NH₃ column density to NH₃ emissions, leading to a lower estimate for global NH₃ emissions. In addition, instead of locally
306 scaling observed NH₃ column by lifetime (Van Damme et al., 2018; Evangeliou et al., 2021; Marais et al., 2021), our method

307 (Eq. (1)) partially accounts for the non-local contribution from transport by including prior NH_3 columns from a full 3-D
 308 simulation and using their difference from observed NH_3 columns to correct prior emissions, which prevents derivation of
 309 large NH_3 emissions in remote regions where observed NH_3 concentrations are driven mainly by transport. Our data filtering
 310 strategy (Sect 2.1 and 2.2) is also crucial to avoid spurious top-down results when satellite coverage is poor and the local
 311 mass balance assumption does not hold.

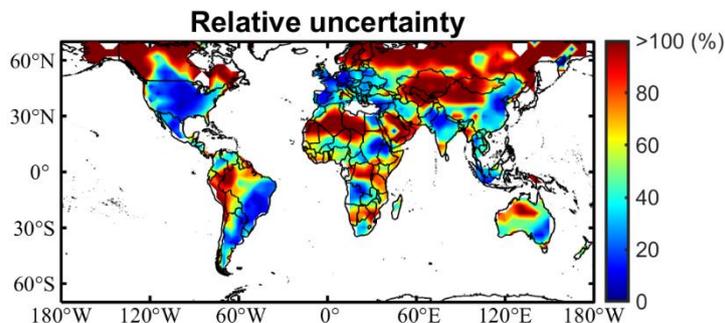

312
 313 **Figure 5.** Comparison of our top-down NH_3 emission estimates (TDE) with other top-down (Fixed 12h and Evangeliou et al. (2021)) and
 314 bottom-up (BUE1 and BUE2) results during 2008-2018. The red line and red bar represent central estimates of the TDE, and the blue
 315 shaded area and the blue error bar indicate the uncertainty evaluated by our study (Sect. 2.4).

316
 317 **Figure 6.** Spatial distribution of NH_3 lifetime (h) diagnosed from GEOS-Chem (Eq. (2)) within the 70°N - 70°S during 2008-2018.
 318 **Fig. 6** shows the spatial variation in NH_3 lifetime diagnosed from the GEOS-Chem simulation. Short NH_3 lifetimes (< 10 h)
 319 are found mainly in northern high latitudes. Short lifetime in eastern China is due to high wet NH_4^+ deposition velocity,
 320 although some regional studies suggested an overestimation of deposition fluxes by the model especially in forest areas (e.g.,
 321 Yangtze River basin) (Zhao et al., 2017; Xu et al., 2018). Very long NH_3 lifetime (> 100 h) occurs over Sahara and Australia,
 322 where dry conditions result in slow wet deposition.

323 3.5 Uncertainty evaluation

324 We derive the uncertainty of top-down estimates from the perturbation tests in **Table 1**. **Fig. 7** shows the global spatial
325 distribution of annual average relative uncertainties of NH_3 emissions (ranges of perturbation tests divided by their averages).
326 The relative uncertainties are large (up to >100%) over northern latitudes, Central Asia, northern Africa, and South America,
327 where observations are often sparse. In comparison, the relative uncertainties are small (<40 %) in well-observed regions
328 including eastern China, northern India, Europe, and the U.S.

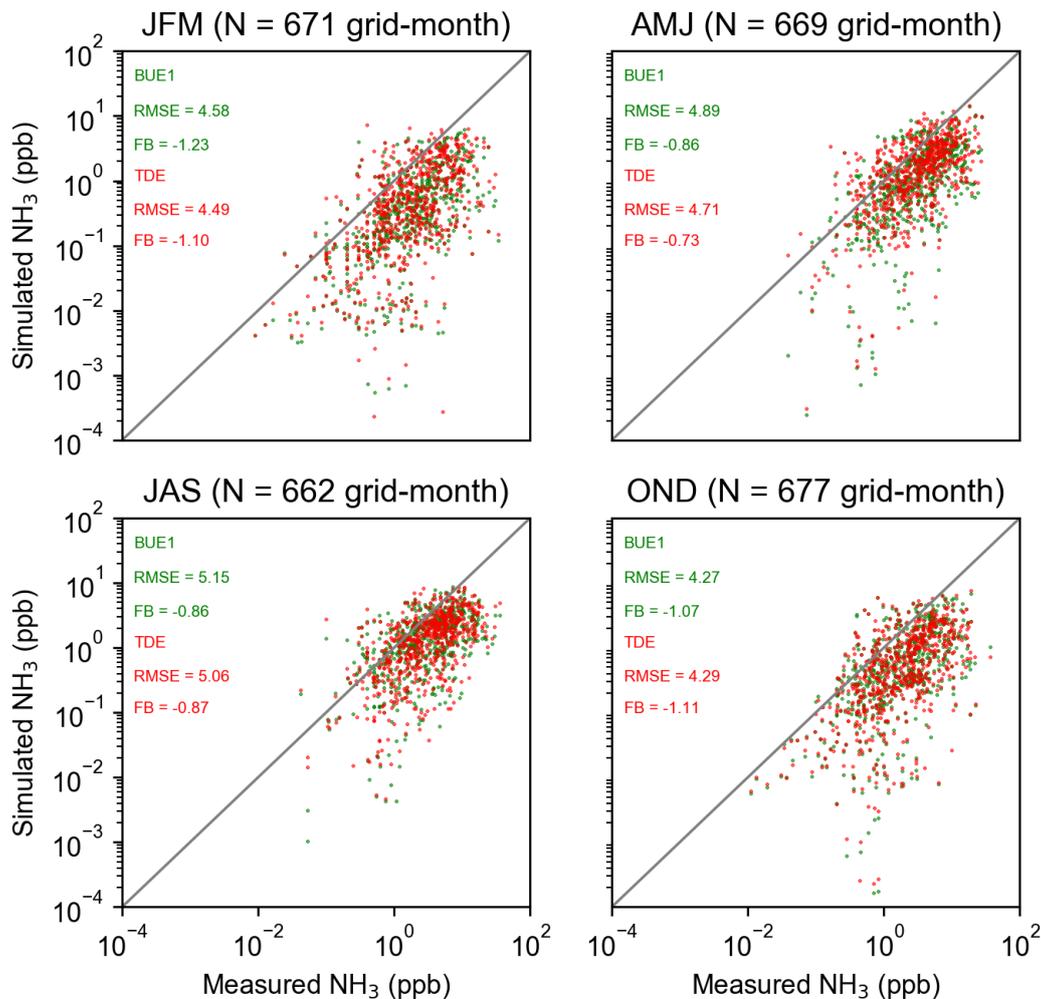

329

330 **Figure 7.** Spatial distribution of TDE relative uncertainty as the discrepancy of emission estimations in parameters perturbation (**Table 1**)
331 divided by the TDE average during 2008-2018.

332 Our fast top-down method (Eq. (1) and Eq. (3)) relies on simplification of NH_3 chemical and physical processes. Therefore,
333 it is not guaranteed that a simulation driven by TDE will generate results in improved agreement with IASI observations. We
334 evaluate the consistency of our results using full GEOS-Chem simulations in the selected years of 2008, 2013, and 2018.
335 Results are shown in **Fig. S5** (fractional bias, FB) and **Table S1** (number of valid grid cells, R^2 , and root mean square error).
336 The GEOS-Chem simulations driven by the prior emissions (BUE1) tends to underestimate NH_3 column density (mean FB
337 \sim 30%), while that driven by our TDE estimates achieves lower biases (mean FB \sim 10%), demonstrating the consistency of
338 our TDE results with IASI observations.

339 We also compare simulated surface NH_3 concentrations with independent ground-based measurements from North America
340 (AMoN, <https://nadp.slh.wisc.edu/networks/ammonia-monitoring-network/>, last access: 3 June 2022), Europe (EMEP,
341 <http://ebas-data.nilu.no/>, last access: 3 June 2022), and South-eastern Asia (EANET, <http://ebas-data.nilu.no/>, last access: 3
342 June 2022). **Fig. 8** shows the comparison by season. Only small adjustments are inferred by our satellite-based estimations in
343 these regions (i.e., North America, Europe, and South-eastern Asia). Thus, TDE and BUE1 show similar performance
344 against these ground measurements. Although the simulation can capture the site-to-site variations reasonably well,
345 simulated surface values are in general biased low compared to observations. This low bias is also reported in the evaluation
346 of previous IASI-based estimates (e.g., [Evangelio et al., 2021](#); [Chen et al., 2021b](#)), which may be due to several reasons, for
347 instance, systematic differences between satellite and surface measurements.

348

349 **Figure 8.** Validation of simulated NH_3 concentrations driven by BUE1 and TDE against ground-based measurements from AMoN, EMEP,
 350 EANET for selected years (2008, 2013 and 2018) in four seasons (January-March, JFM; April-June, AMJ; July-September, JAS; October-
 351 December, OND). Scatterplots are plotted in log scale and average RMSE (ppb) and FB (%) for each season are inset.

352 4 Conclusions

353 This study quantifies global ammonia (NH_3) fluxes monthly from 2008 to 2018 at $4^\circ \times 5^\circ$ resolution, through a fast top-
 354 down method that incorporates IASI satellite observations and GEOS-Chem model simulations. The top-down method
 355 updates the prior NH_3 emissions with a correction term positively proportional to the difference of the observed and
 356 simulated NH_3 concentrations, and inversely proportional to the lifetime diagnosed from a CTM. This method revises
 357 previously proposed fast top-down methods in two aspects. First, we account for thermodynamic equilibrium within the NH_x
 358 family in diagnosing NH_3 lifetime, while previous studies either assume a globally constant lifetime or treat conversion from
 359 NH_3 to NH_4^+ as a terminal sink. Second, our formulation linearizes the column-emission relationship at prior emissions as

360 opposed to zero emissions in the previous method, which in general reduces errors from the local mass balance
361 approximation. Another improvement is that we apply several data filtering procedures to exclude unreliable top-down
362 results that are not sufficiently constrained by observations or affected by large deviations from the local mass balance
363 assumption. The top-down method developed in this study is particularly useful for long-term global analysis of emission
364 trends, because it largely accounts for the impact of meteorology through the CTM simulation and requires only small
365 amount of computation relative to a full-fledged inversion.

366 We apply this improved fast top-down method to IASI NH₃ column observations from 2008 to 2018. We find that the BUE1
367 underestimates NH₃ emission over South America (62 %) and tropical Africa (69 %), but overestimates over India (14 %)
368 and Canada (33 %). The bottom-up inventory agrees with the top-down estimate over the U.S., Europe, and eastern China
369 (i.e., within 10 %). Our analysis also shows significant increases in India (13 % decade⁻¹), tropical Africa (33 % decade⁻¹),
370 and South America (18 % decade⁻¹) during the study period, consistent with intensifying agricultural activities over these
371 regions. An analysis of agricultural statistics suggests that the increase in tropical Africa is likely driven by growing
372 livestock population and that in South America by increasing fertilizer usage.

373 We show that large increases in NH₃ concentrations in eastern China is mainly driven by rapid decreases in SO₂ emissions in
374 recent years. By accounting for observed SO₂ columns, we find that NH₃ emissions from eastern China are significantly
375 decreasing during 2008-2018 (-19 % decade⁻¹), with a larger negative trend after 2013 (-28 % decade⁻¹), as compared to a
376 significant positive trend (61 % decade⁻¹) derived from assimilating only NH₃ data. Similarly, a lack of trend in observed
377 NH₃ concentrations over India is due to concurrent increases in SO₂ and NH₃ emissions. After including observed SO₂
378 columns in the calculation, we estimate a 13 % increase in NH₃ emissions over India, with a significant post-2013 positive
379 trend (30 % decade⁻¹). These results from assimilating both NH₃ and SO₂ data is more consistent with the agricultural
380 statistics in China and India. The multi-satellite (SO₂ and NH₃) method is only applied in India and China in this study. To
381 extend this idea globally requires development of formulations for varied sulfate-nitrate-ammonium aerosol regimes and
382 needs to be addressed in a future study.

383 Our estimate for global total NH₃ emission is 78 (70-92) Tg a⁻¹, about 30 % higher than the BUE1 estimate. This contrasts
384 with a much higher estimate (180 Tg a⁻¹) derived from Evangeliou et al. (2021) also using IASI data. The discrepancy can be
385 primarily attributed to a longer NH₃ lifetime (i.e., global average 21 h) diagnosed in our method, which represents a greater
386 sensitivity of NH₃ column to emissions, and a more conservative data filtering strategy, which removes potentially unreliable
387 top-down results. Our diagnosis of NH₃ lifetime is an improvement over Evangeliou et al. (2021), by accounting for the
388 thermodynamic equilibrium between gas phase NH₃ and aerosol phase NH₄⁺ in our formula. We show with model
389 simulations, our top-down estimate achieves better consistency with IASI observations, compared to the bottom-up emission
390 inventory.

391

392 *Data availability.*

393 The IASI L2 ammonia satellite observations are available at the AERIS data infrastructure (<https://iasi.aeris-data.fr/>). The
394 ERA5 skin temperature and GFAS fire emission can be request through Copernicus Climate Data Store
395 (<https://cds.climate.copernicus.eu/cdsapp#!/home>). Agricultural data are available through Food and Agriculture
396 Organization of the United Nations (FAO) (<http://www.fao.org/faostat>). The GEOS-Chem model can be retrieved from
397 10.5281/zenodo.3974569. All the other data and scripts used for the present publication are available under MIT license on
398 GitHub: <https://github.com/bnulzq/NH3-emission.git> and can be obtained from corresponding author upon request.

399 *Author contributions.*

400 ZL and YZ designed the study. ZL performed the simulations and analyses and wrote and coordinated the paper. WC
401 contributed to the model simulations for consistency evaluation. LC, MVD, and PFC developed the IASI-NH₃ satellite
402 product. ZL and YZ wrote the paper with inputs from all authors.

403 *Competing interests*

404 The contact author has declared that neither they nor their co-authors have any competing interests.

405 *Acknowledgements.*

406 This study is supported by Westlake University. We thank the High-Performance Computing Center of Westlake University
407 for the facility support and technical assistance. We acknowledge the AERIS data infrastructure <https://www.aeris-data.fr> for
408 providing access to the IASI data. The IASI L1c data are received through the EUMETCast near real-time data distribution
409 service. Research at ULB was supported by the Belgian State Federal Office for Scientific, Technical and Cultural Affairs
410 (Prodex HIRS) and the Air Liquide Foundation (TAPIR project). LC is Research Associate supported by the Belgian F.R.S.-
411 FNRS. Hersbach et al., (2020) was downloaded from the Copernicus Climate Change Service (C3S) Climate Data Store. The
412 results contain modified Copernicus Climate Change Service information 2020. Neither the European Commission nor
413 ECMWF is responsible for any use that may be made of the Copernicus information or data it contains. IASI is a joint
414 mission of Eumetsat and the “Centre National d’Études Spatiales” (CNES, France). We acknowledge the constructive
415 comments and suggestions from Prof. Peter Hess from the Cornell University, Dr. Yi Wang from the University of Iowa, and
416 Dr. Shixian Zhai from Harvard University. We also acknowledge Dr. Nikolaos Evangeliou from Norwegian Institute for Air
417 Research for providing his NH₃ emission flux data and for discussions with ZL.
