15 **Abstract**

16 In this study, we analyze the diurnal variations and formation mechanism of low
17 clouds at different elevations. We further discuss whether there exists triggering
18 mechanism for convection over the Tibetan Plateau (TP), and whether there is an
19 association among low air density, strong turbulence and ubiquitous “popcorn-like”
20 cumulus clouds. The buoyancy term (BT) and shear term (ST) over the TP are
21 significantly greater than those at the low elevation, which is favorable for the
22 formation of increasing planetary boundary layer height (PBLH), and also plays a key
23 role in the convective activities in the lower troposphere. The lifting condensation
24 level (LCL) increases with the increasing of PBLH-LCL over the TP. From the
25 viewpoint of global effects, the triggering effects of the dynamical structure within the
26 boundary layer on convective clouds in the Northern Hemisphere are analyzed. There
27 are strong ST and BT at two high elevation regions (TP and Rocky Mountains), and
28 the strong thermal turbulence results in obvious positive value of PBLH-LCL at high
29 elevation regions under low RH condition in the Northern Hemisphere. The values of
30 PBLH-LCL slightly greater than zero correspond spatially to increased low cloud
31 cover (LCC) in the central part of Rocky Mountains, but the obvious large-scale
32 subsidence on both sides of the mountain leads to strong inversion above PBL and
33 lower RH in PBL, which further lead to decreased LCC in these areas. Thus less LCC
34 is generated at Rocky Mountains compared to the TP.

35 Introduction

36 The Tibetan Plateau (TP), which resembles a "third pole" and a "world water
37 tower", plays an important and special role in the global climate and energy–water
38 cycle (Xu et al., 2008; Wu et al., 2015). The TP covers a quarter of China.
39 Additionally, the average altitude of the TP is 4000 meters, reaching 1/3 of the
40 tropopause height, so it is called the "World Roof". Cumulus convection over the TP
41 transfers heat, moisture and momentum into the free troposphere, which can impact
42 the atmospheric circulation regionally and globally (Li and Zhang, 2016; Xu et al.,
43 2014) and reveals the important "window effect" for the transfer and exchange of
44 global energy and water vapor over the TP. It is the dynamic effect from the special
45 heat source that constitutes the "window effect" and "thermally driven" mechanism
46 over the TP.

47 The results of the second Tibetan Plateau Experiments (TIPEX II), which were
48 carried out in 1998, show that the strong convective plumes within PBL observed by
49 sodar and a frequently occurred deep mixed layer (>2 km) can lead to ubiquitous
50 "popcorn-like" cumulus clouds in Dangxiong, as proposed by Zhou et al. (2000), and
51 Xu et al. (2002) came up with a comprehensive physical pattern of land-air dynamic
52 and thermal structure on the TP (Xu et al., 2002; Zhou, 2000). The previous studies
53 have done many valuable researches on the triggering mechanism of moist convection
54 over moist and dry surfaces based on atmospheric observations and simulations (Ek
55 and Mahrt, 1994; Findell and Eltahir, 2003; Gentine et al., 2013). For dry surface, the
56 weak stratification and strong sensible heat flux result in the rapid growth of PBLH so
57 that the relative humidity at the top of the boundary layer RH_{top} increases rapidly,
58 which favors the formation of clouds. For moist surface, strong stratification and
59 evaporation (small bowen ratio) not only cause slow growth of PBLH but also
60 increase the mixed layer specific humidity and RH_{top} , which favor the formation and
61 development of clouds. Taylor et al. (2012) found that the afternoon rain falls
62 preferentially over soils that are relatively dry compared to the surrounding area,
63 especially for semi-arid regions. Guillod et al. (2015) reconciled spatial and temporal
64 soil moisture effects on the afternoon rainfall. They showed that afternoon
65 precipitation events tend to occur during wet and heterogeneous soil moisture
66 conditions, while being located over comparatively drier patches. Tuttle et al. (2016)
67 showed the empirical evidence of contrasting soil moisture–precipitation feedbacks
68 across the United States, and they found that soil moisture anomalies significantly
69 influence rainfall probabilities over 38% of the area with a median factor of 13%.
70 Findell et al. (2003) analyzed the model results over dry and wet soils in Illinois. They
71 summarized the predictive capability of rain and shallow clouds by using the
72 convective triggering potential (CTP) and a low-level humidity index, with HI_{low} as
73 measures of the early morning atmospheric setting. Our previous studies pointed out
74 that the developments of these cumulus clouds are related to the special large scale
75 dynamic structure and turbulence within PBL over the TP (Xu et al., 2014; Wang et al.,

76 2020). In addition, Wang et al., (2020) pointed out that, despite the same relative
77 humidity between eastern China and the TP, the lower temperature over the TP results
78 in a lower lifting condensation level. With the same surface sensible heat flux, lower
79 air density over the TP results in a larger buoyancy flux and a deeper boundary layer.
80 All the above results indicate the topography of the TP plays a major role in
81 increasing the occurrence frequency of strong convective clouds (Luo et al., 2011).
82 This conclusion is consistent with the viewpoint of Flohn (1967) who emphasized the
83 chimney effect of the huge cumulonimbus clouds on heat transfer in the upper
84 troposphere.

85 The TP is one of the regions in China that is featured with high frequency of
86 cumulus clouds, and the development of cumulus system is related to both the
87 turbulence and special dynamical structure in PBL over the TP. The vertical motion
88 over the TP is associated with the anomalous convective activities. However, as Li
89 and Zhang (2016) mentioned, the details of PBL process are not very clear. The same
90 is true for the diurnal variations and formation mechanism of low clouds over the TP
91 and low elevation regions. The different variation characteristics of these low clouds
92 at different elevations and regions also need to be discussed and analyzed. Moreover,
93 we need to investigate whether there exists “high efficiency” triggering mechanisms
94 for convection over the TP, and whether there is an association among low air density,
95 strong turbulence and ubiquitous “popcorn-like” cumulus clouds. Is there also strong
96 turbulence at higher elevation regions with lower air density in the globe? What is the
97 impact of the large scale vertical motions on clouds? Because both the TP and Rocky
98 Mountains are high elevation regions covering large mid-latitude areas, in this study
99 we mainly focus on these two regions to analyze the above scientific questions.

100 **2 Observational and reanalysis data**

101 We use in situ measurements of temperature (T) and relative humidity (RH) at 2 m
102 height, surface pressure data every hour, and low cloud cover (LCC) every three
103 hours from 2402 automatic weather stations from June to August of 2010-2019 in
104 China. LCC here refers to the fraction of the sky covered by low clouds as estimated
105 by human observers, including five cloud types: nimbostratus (Ns), stratocumulus
106 (Sc), stratus (St), cumulus (Cu), and deep convection (DC). These surface observation
107 datasets are provided by China National Meteorological Information Center.

108 In addition, we use the hourly $0.25^\circ \times 0.25^\circ$ ERA5 reanalysis surface-layer data
109 in summer (June 1 to August 31) from 2010 to 2019 (Hersbach et al., 2020).

110 We use more than 4 years (from June 15 2006 to August 31 2010) of the satellite
111 (CloudSat radar and Calipso lidar)-merged cloud classification product
112 2B-CLDCLASS-lidar to calculate the mean LCC with $1^\circ \times 1^\circ$ resolution at about 2:00
113 pm and 2:00 am LT in summer. The introduction of this product and details of the
114 LCC calculation methods are summarized in Sassen and Wang (2008) and Wang et al
115 (2020).

116 We use a Gaofen 4 (GF 4) visible satellite image with the spatial resolution of 50
117 m on August 4 of 2020 to show the organized structures (cellular convection) in

118 southeastern TP, as shown in Figure 1. GF 4 is a geostationary earth observation
 119 satellite in the Gaofen series of Chinese civilian remote sensing satellites. We also use
 120 the 1 year (from June 1 to August 31 of 2016) geostationary satellite himawari-8
 121 retrieval product (cloud top height) over land in East Asia.

122 In this study, we also use temperature (T) at 2 m height, relative humidity (RH) at
 123 2 m height, surface pressure and planetary boundary layer height (PBLH) from ERA5
 124 reanalysis data from 2010 to 2019. To be specific, the above four variables represent
 125 hourly average values for each month (24 values in total for a month). The lifting
 126 condensation level (LCL) is calculated by the method proposed by (Romps, 2017).

127 Using sensible heat flux H , Northward turbulent surface stress τ_y and Eastward
 128 turbulent surface stress τ_x from ERA5 reanalysis data, we calculate the buoyancy
 129 term (BT) ($g/\theta_v \overline{w'\theta'_v}$) and shear term (ST) ($-\partial\bar{u}/\partial z \overline{u'w'}$) in the TKE equation for each
 130 grid. Both of these two terms can be used to analyze the effect of boundary layer
 131 turbulence in surface layer on convection. The details of the method for computing
 132 BT and ST are as follows:

133 The shear term (ST) ($-\partial\bar{u}/\partial z \overline{u'w'} - \partial\bar{v}/\partial z \overline{v'w'}$) and buoyancy term (BT) ($g/\theta_v \overline{w'\theta'_v}$)
 134 in the TKE equation maintain the turbulent motions. In order to simplify calculations,
 135 the x-axis is directed along the average wind. Assuming horizontal homogeneity and
 136 no mean divergence, the TKE equation is written as

$$137 \quad \frac{\partial\bar{e}}{\partial t} = \frac{g}{\theta_v} \overline{w'\theta'_v} - \overline{u'w'} \frac{\partial\bar{u}}{\partial z} - \frac{\partial(\overline{w'e})}{\partial z} - \frac{1}{\rho} \frac{\partial(\overline{w'p'})}{\partial z} - \varepsilon. \quad (1)$$

138 The left side of eq. (1) is the local time variation $\partial\bar{e}/\partial t$, and the terms on the
 139 right-hand side of eq. (1) describe the buoyancy and shear energy production or
 140 consumption, turbulent transport of \bar{e} , pressure correlation and viscous dissipation
 141 (Stull, 1988).

142 Here we use eq. (2) to calculate the virtual potential temperature θ_v , and $\overline{w'\theta'_v}$ is
 143 derived from eq. (3). Finally, we derive BT.

$$144 \quad \theta_v = T(1 + 0.608q) \left(\frac{p_0}{p} \right)^{\frac{R}{c_p}}, \quad (2)$$

$$145 \quad H = \rho c_p \overline{w'\theta'_v}, \quad (3)$$

146 Where $g = 9.8 \text{ m s}^{-2}$ is the gravitational constant, and $H \text{ (W m}^{-2}\text{)}$ is the sensible heat
 147 flux, $\rho \text{ (kg m}^{-3}\text{)}$ is the air density, R is the specific gas constant for dry air, $c_p \text{ (=1004 J}$
 148 $\text{kg}^{-1} \text{ K}^{-1}\text{)}$ is the specific heat of air at constant pressure, T is the air temperature at 2 m
 149 height, q is the specific humidity at 2 m height, p_0 and p are standard atmospheric
 150 pressure and surface pressure, respectively.

151 For ERA5 reanalyze data, the $\overline{\partial u}/\partial z$ in the surface layer is estimated as

$$152 \quad \frac{\overline{\partial u}}{\partial z} = \phi_m(\zeta) \frac{u_*}{kz}, \quad (4)$$

153 (i) Unstable conditions ($\zeta = z/L < 0$). The non-dimensional wind profiles ϕ_m are
 154 deduced from eq.(5), as proposed by (Dyer, 1974):

$$155 \quad \phi_m = (1 - 16\zeta)^{-1/4}, (\zeta < 0) \quad (5)$$

156 (ii) Stable conditions ($\zeta = z/L > 0$). The stable profile functions are assumed to have
 157 the empirical forms proposed by Holtslag and Bruin (1988). The universal profile
 158 stability function ψ_m can be written as

$$159 \quad \psi_m = -b \left(\zeta - \frac{c}{d} \right) \exp(-d\zeta) - a\zeta - \frac{bc}{d}, \quad (6)$$

160 Where $a = 1$, $b = 2=3$, $c = 5$, and $d = 0.35$. Then ϕ_m can be estimated with the
 161 help of the relationship $\phi_m = 1 - \zeta (\partial \psi_m / \partial \zeta)$.

$$162 \quad \zeta = \frac{z}{L}, L = - \frac{(\tau/\rho)^{3/2}}{\kappa(g/\theta_v)(H/\rho c_p)}, \quad (7)$$

$$163 \quad \tau = \sqrt{\tau_x^2 + \tau_y^2}, \quad (8)$$

$$164 \quad \tau = \rho u_*^2, \quad (9)$$

$$165 \quad \tau = -\rho \overline{u'w'}. \quad (10)$$

166 Where the von Karman constant $\kappa=0.4$, and $z = 10$ m. \overline{u} is the horizontal wind
 167 speed at level z and u_* is the frictional velocity. The stability parameter z/L is defined,
 168 and the Obukhov length L can be directly written as a function of τ and H in eq.(7)
 169 (Gryanik et al. 2020). τ_x and τ_y are the Eastward and Northward turbulent surface
 170 stress, respectively. τ is turbulent fluxes of momentum, which can be calculated by
 171 using eq. (8). Then we use eq. (9) to derive u_* . We also use eq. (10) to derive $\overline{-u'w'}$.
 172 Finally, we derive ST.

173

174 3 Results

175 Figure 2 shows the spatial distribution of over-land low cloud cover (LCC) in

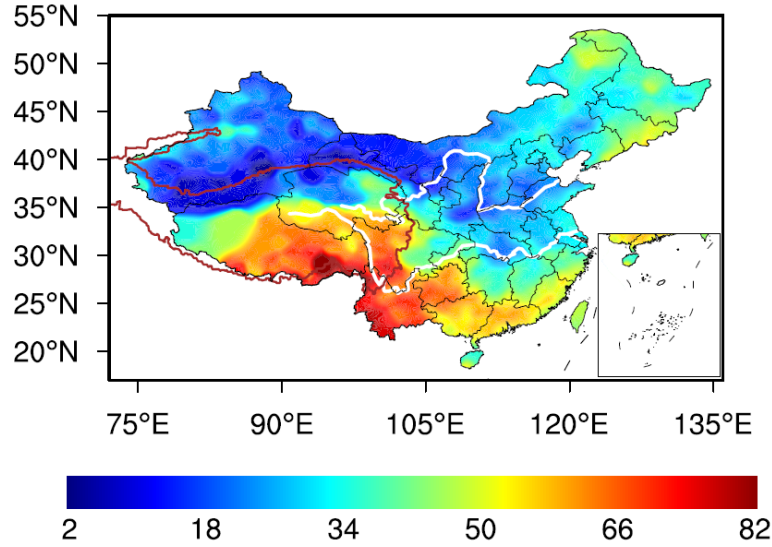

176 China from June to August of 1951-2019. Compared to the low LCC in eastern China,
 177 the high value areas of LCC are mainly located in the mid-eastern TP and the area of
 178 the upper Yangtze River Valley. But low LCC is also identified in western and
 179 northern parts of TP. We will make a further discuss about it in subsequent paragraphs.
 180 Using four years of CloudSat-Calipso satellite data, Li and Zhang (2016) confirmed
 181 that the climatological occurrence of cumulus over the TP is significantly greater than
 182 that in mid-eastern China on the same latitude. The elevated land surface with strong
 183 radiative heating makes the massive TP a favorable region for initiating convective
 184 cells with a high frequency of cumulonimbus and mesoscale convective systems
 185 (Sugimoto and Ueno, 2012). As a strong heat source, the TP has frequent convective
 186 activities in summer. During the TIPEX II in 1998, the long and narrow thermal
 187 plume corresponding with vigorous cellular convection on micro-scale was observed
 188 by sodar in Dangxiang. As shown in Figure 1, the shallow convective clouds on a
 189 horizontal scale from hundreds of meters to several kilometres over the southeastern
 190 TP (92.7-96.2E, 29.5-31.3N) are probably related to the organized eddies on the
 191 meso-scale and micro-scale over the TP. The cloud fraction over the southeastern TP
 192 is about 31.3%.

193 As shown in Figure 3, in general, LCC increases with the increasing elevation.
 194 The median of LCC_H is significantly greater than those of LCC_L and LCC_M
 195 throughout the day. The diurnal variations of LCC_L and LCC_M are generally
 196 distributed in unimodal pattern, with the maximum appearing at 2:00 pm BT (median
 197 $LCC_L = 37\%$, $LCC_M = 38\%$) and low values ($\sim 20\%$) are maintained during the night.
 198 The diurnal variation of LCC_H presents a bimodal curve with the maximum appearing
 199 at 5:00 pm BT (median $LCC_H = 69\%$) and the secondary local maximum appearing at
 200 8:00 am BT (median $LCC_H = 61\%$). Compared to the low elevation, the interquartile
 201 ranges (IQRs) of LCC_H are smaller than those of LCC_L and LCC_M , which imply the
 202 LCC_H maintains high values during the day. To further confirm and compare the
 203 above results with in situ measurements, using ERA5 LCC data, we also add Figure
 204 S1 to show the diurnal cycle of LCC in summer in East Asia and North America in
 205 the supplementary material.

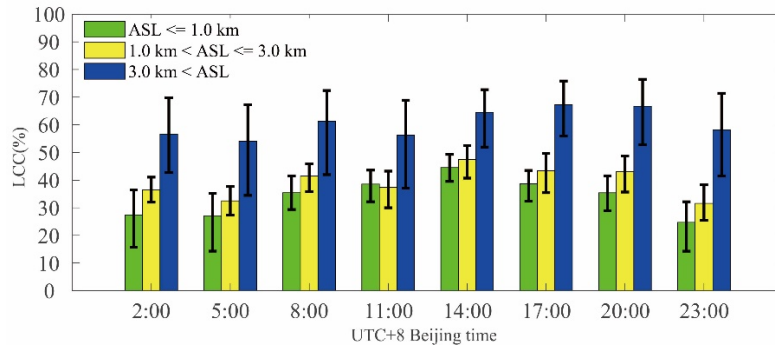

206

207 Figure 1. The (a) digital number (DN) and (b) spatial distribution of cloud in
 208 southeastern TP from geostationary earth observation satellite Gaofen 4 (GF4) at
 209 12:00 pm Beijing time (about 10:20 am local time) on August 4 of 2020. Here we
 210 simply use $DN = 250$ as a threshold. All the grids in Figure (a) are divided into two
 211 classes ($DN > 250$, cloud; $DN < 250$, no cloud), and then we give Figure (b).

212

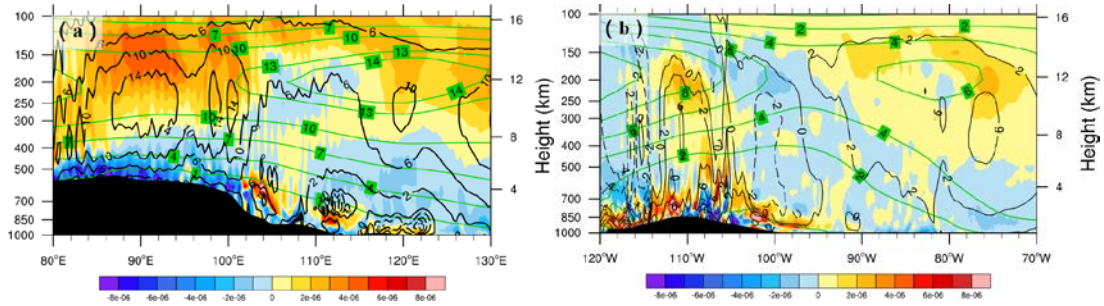

213 Figure 2. The summer mean LCC derived from surface observations from 1951 to
 214 2019 in China. The thick
 215 red contour denotes the 2.5 km topography height referred to as the TP. The white
 216 lines located in northern and southern parts of China denote the Yellow and Yangtze
 217 River, respectively.

218

219 Figure 3. The diurnal cycle of LCC in summer from 2010 to 2019 at different
 220 altitudes above sea level (ASL): $ASL \leq 1.0$ km (LCC_L), 1.0 km $<$ $ASL \leq 3.0$ km
 221 (LCC_M), and 3.0 km $<$ ASL (LCC_H). It should be noted that all the sites are ranged
 222 from 27N to 40N in China, and each sample is derived from monthly mean LCC at a
 223 particular time in summer for each site. The bar and error bar represent the median
 224 values and interquartile ranges (IQRs) of LCC, respectively. The subscripts L, M and
 225 H of LCC denote the low, medium and high clouds, respectively.

226

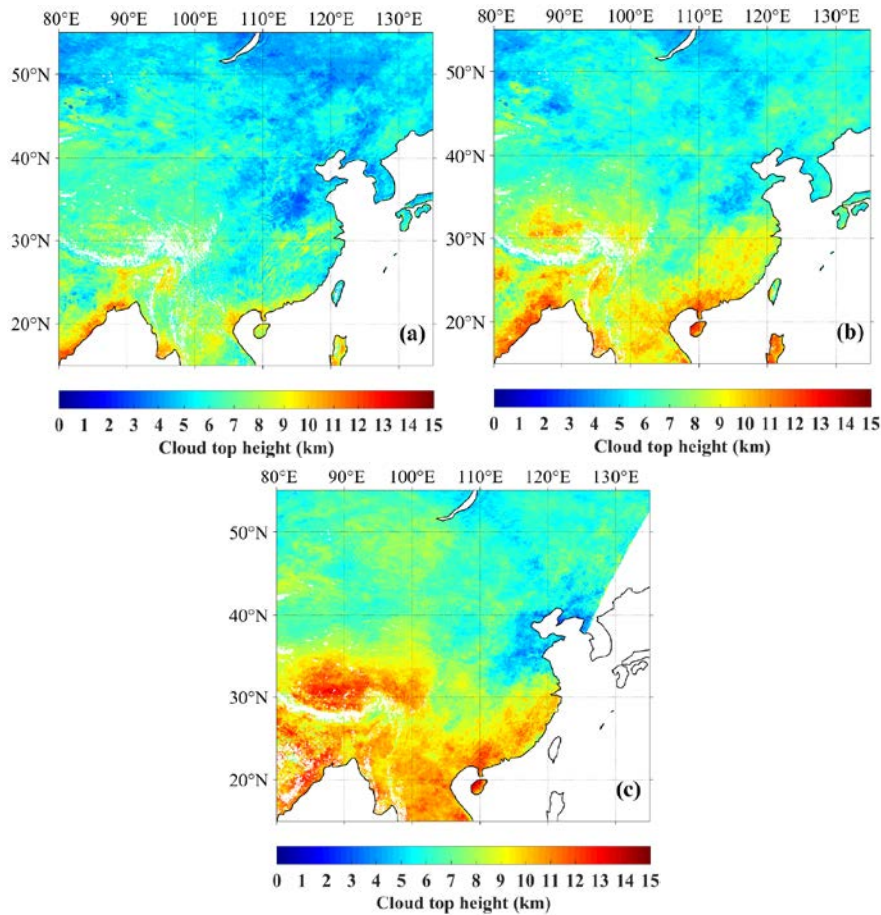

227

228

229 Figure 4. Vertical distribution of divergence (s^{-1}) (shaded) at the latitude across
 230 sections from 30N to 35N in (a) East Asia and (b) North America. The green and
 231 black contours denote the summer mean U- ($m s^{-1}$) and W- ($10^{-2} m s^{-1}$) wind
 232 components at local time 2:00 pm from 2010 to 2019 along 30N–35N with the zonal
 233 circulations, respectively. The solid and dash contour lines represent the positive and
 234 negative values, respectively. The black shaded areas represent topography. The
 235 PBLH (green) and LCL (yellow) versus longitude in (c) East Asia and (d) North
 236 America. The bar and error bar represent the median values and interquartile ranges
 237 (IQRs), respectively.

On the other hand, we note that, compared to eastern China, there is no obvious decrease trend for the LCC over the TP from late afternoon to evening as shown in Figure 3. Based on the spatial distribution of topography in the Northern Hemisphere as shown in Figure 7 (a), it is clear that both the TP (27-40N, 70-105E) and Rocky Mountains (27-40N, 103-120W) in North America are two large areas with high elevations in mid-latitude regions in the Northern Hemisphere, so here we select these two typical large topography regions to analyze the triggering effects of large topography and related dynamical structure within the boundary layer on convective clouds. In general, there are obvious large scale ascending motions from near surface layer to upper troposphere over the TP, which correspond with the convergence at 500 hPa and the divergence at 200 hPa, as shown in Figure 4 (a). Figure 4 (c) shows there are generally positive PBLH-LCL (\sim 500 m) over the TP, and the median and IQR of PBLH are close to those of LCL in East Asia. These results are consistent with the conclusions proposed by Xu et al. (2014) and Wang et al. (2020). In contrast, Figure 4 (b) shows there are only weak large scale ascending motions from near surface layer to middle troposphere over the Rocky Mountains, and the large-scale subsidence on both sides of the Rocky Mountains can lead to strong inversion above PBL and lower RH in near surface layer. The former restricts the growth of PBLH during the day,

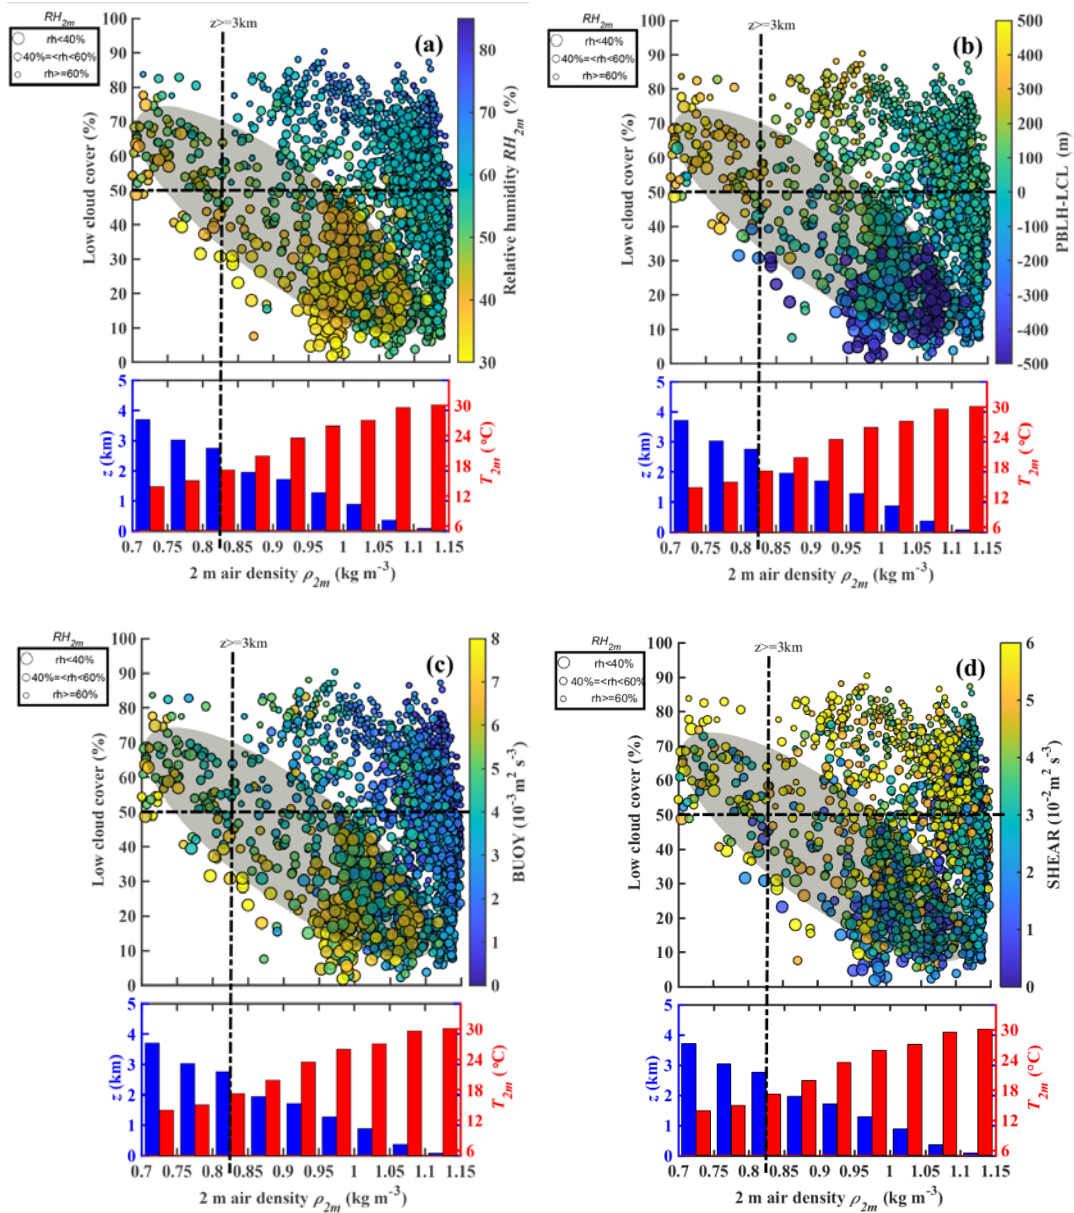

262 while the latter leads to the increased LCL. Thus, negative PBLH-LCL is identified on
263 both sides of the Rocky Mountains (30-35N, 110-120W and 30-35N, 100-105W),
264 especially for the western Rocky Mountain (30-35N, 110-120W) with strong
265 large-scale subsidence, as shown in Figure 4 (d). Dynamic processes of vapor
266 transport are generated because of the thermal structure of the TP, which is similar to
267 the conditional instability of the second kind (CISK) mechanism of tropical cyclones.
268 It should be pointed out that there are large scale descending motions at 500 hPa in
269 part of western TP and Qaidam Basin as shown in Figure S2, which lead to less LCC
270 in these regions compared to the other parts of the TP, as shown in Figure 2. In
271 addition, the meteorological stations in northern part of TP (34-36N, 80-90E) are
272 scarcely and unevenly distributed, and therefore the low LCC in the Taklamakan
273 Desert leads to fake low LCC values in northern part of TP (80-90E, 34-36N), as
274 shown in Figure 2. In fact, there are high LCC in these regions as shown in Figure 7
275 (e). Figure 5 shows the spatial distribution of day time variations of cloud top height in
276 summer. Compared to eastern China at the same latitude, the cloud top height
277 increases significantly from 2:30 pm (~7 km) to 6:30 pm (~14 km) over the TP. The
278 cloud top height approaches the tropopause (~14 km) in the evening, which implies
279 the frequent occurrence of deep convective clouds at this time. This result is
280 consistent with the observation of millimeter-wave radar in Naqu (Yi, 2016).

281 By comprehensively analyzing the second Tibet Plateau Experiment (TIPEX II)
282 sodar data, Xu et al. (2002) and Zhou et al. (2000) found that, with narrow upward
283 motion and time scale from 1.2 h to 1.5 h, the maximum upward motion of the
284 thermal turbulence was identified at the height of about 120 m above the surface, with
285 the vertical speed up to 1 m s^{-1} . They also found symmetrical and wide downward
286 motion area on either side of the narrow upward motion zone. The question arises as
287 to whether there is a relationship between the formation and evolution of frequent
288 "pop-corn-like" convective clouds and micro-scale thermal turbulence in the
289 atmospheric convective boundary layer over the TP. Xu et al., (2012) speculate these
290 low clouds are probably initiated by strong thermal turbulence under low air density
291 conditions. Compared to the low elevation in eastern China, the increased thermal
292 turbulence associated with low air density over the TP leads to the different
293 turbulence characteristics of convective boundary layer (CBL). The CBL is mainly
294 driven by buoyancy heat flux, and the thermal turbulence with organized thermal
295 plume is not totally random (Young, 1988a; Young, 1988b). The BT and ST over the
296 TP are significantly greater than those at the low elevation, which play key roles in
297 the convective activities in lower troposphere.

298 By using the statistical results from sodar data in the second Tibetan Plateau
299 Experiment for atmospheric sciences (TIPEX II), Zhou et al. (2000) calculated the BT
300 and ST at the height of 50 m under strong convection conditions in Dangxiong
301 (located at central TP). The results indicate that the BT is comparable to ST. Both the
302 thermodynamic and dynamic processes have important influences on the convective
303 activities. Both the BT and ST in the surface layer in Dangxiong are almost an order
304 of magnitude greater than those at low elevation given by Brummer (1985) in North
305 Sea and Weckwerth et al. (1997) in Florida. Direct measurements from the Third

306 Tibetan Plateau Experiments (TIPEX III) also confirmed that surface buoyancy flux
307 over the TP is significantly larger than that in eastern China (Zhou, 2000; Wang et al.,
308 2016). Both the sodar data in TIPEX II and boundary layer tower data in TIPEX III
309 showed contributions of BT and ST to the turbulent kinetic energy in the lower
310 troposphere are larger over the TP than over the southeastern margin of the TP and the
311 low-altitude Chengdu Plain (Zhou, 2000; Wang et al., 2015). What is the relationship
312 between high frequent low cloud and the above physical quantities (e.g. turbulence
313 structure, temperature and humidity) under low air density conditions over the TP?
314 The physical mechanism should be discussed and analyzed. In addition, at low
315 elevation in eastern China, the question arises as to whether or not the variations of
316 PBLH and LCL favor the formation and development of low clouds.

317 As shown in Figure 6 (a), compared to the low elevation, there is larger LCC ($LCC >$
318 50%) over the TP ($ASL > 3$ km) under low RH_{2m} condition ($RH_{2m} < 40\%$). In contrast,
319 larger LCC mostly corresponds to higher RH_{2m} condition at low elevation, which is
320 consisted with our common sense. The above interesting phenomenon can be
321 explained by the differences of PBLH-LCL between the TP and low elevation on
322 summer afternoons, which are mainly attributed to two mechanisms. With a similar
323 sensible heat flux, the lower air density over the TP leads to greater surface buoyancy
324 flux (or BT) as shown in Figure 6 (c), which is conducive to the increase of PBLH
325 over the TP. Figure 6 (d) shows great ST over the TP, which is mainly attributed to
326 large wind speed. Although here we only show the ST in the surface layer, strong
327 wind shear in the boundary layer probably also plays a role in increasing PBLH over
328 the TP. On the other hand, with a similar RH, Wang et al. (2020) have indicated that,
329 compared to the low elevation in eastern China, the lower temperature over the TP
330 leads to a lower LCL. Together these two mechanisms lead to a greater (PBLH-LCL)
331 difference over the TP on summer afternoons, which increases the probability of air
332 parcels reaching the LCL and forming clouds as shown in Figure 6 (b). In most cases,
333 the positive value of PBLH-LCL as well as the great BT and ST over the TP
334 corresponds with larger LCC ($LCC > 50\%$) under low RH_{2m} condition ($RH_{2m} < 60\%$),
335 which implies the enhanced local LCC is relevant to the diurnal variation of the PBL
336 process. In contrast, for the eastern China, in most cases, the increased LCC ($LCC >$
337 50%) generally corresponds with high RH_{2m} ($RH_{2m} > 60\%$), and the LCC is not
338 significantly correlated with PBLH-LCL or BT and ST, which implies the other
339 factors besides the PBL process (e.g. large scale ascending motion) play a more
340 important in LCC.

341

342

343 Figure 6. The relationships among monthly means of low cloud cover LCC, ρ_{2m} and
 344 (a) RH_{2m} , (b) PBLH-LCL, (c) BT and (d) ST at 2:00 pm (BT) from 2010 to 2019 in
 345 summer in China. The samples are divided into three groups: $RH_{2m} \geq 60\%$ (small
 346 size dots), $60\% > RH_{2m} \geq 40\%$ (median size dots) and $RH_{2m} < 40\%$ (large size dots).
 347 The LCC, T_{2m} and RH_{2m} are observed by in situ measurements, and PBLH, LCL, BT
 348 and ST are derived from ERA5 reanalysis data. Here we use the nearest neighbor
 349 gridding method to derive PBLH, LCL, BT and ST at each site. The blue and red
 350 histograms show an approximate relationship between ρ_{2m} and surface elevation
 351 above sea level z , air temperature at 2 m (T_{2m}) at the bottom of Figure 2a, respectively.
 352 The dots with lower RH_{2m} ($RH_{2m} < 40\%$) are mostly distributed within grey shaded
 353 elliptic regions as shown in Figure 6 (a)-(d).

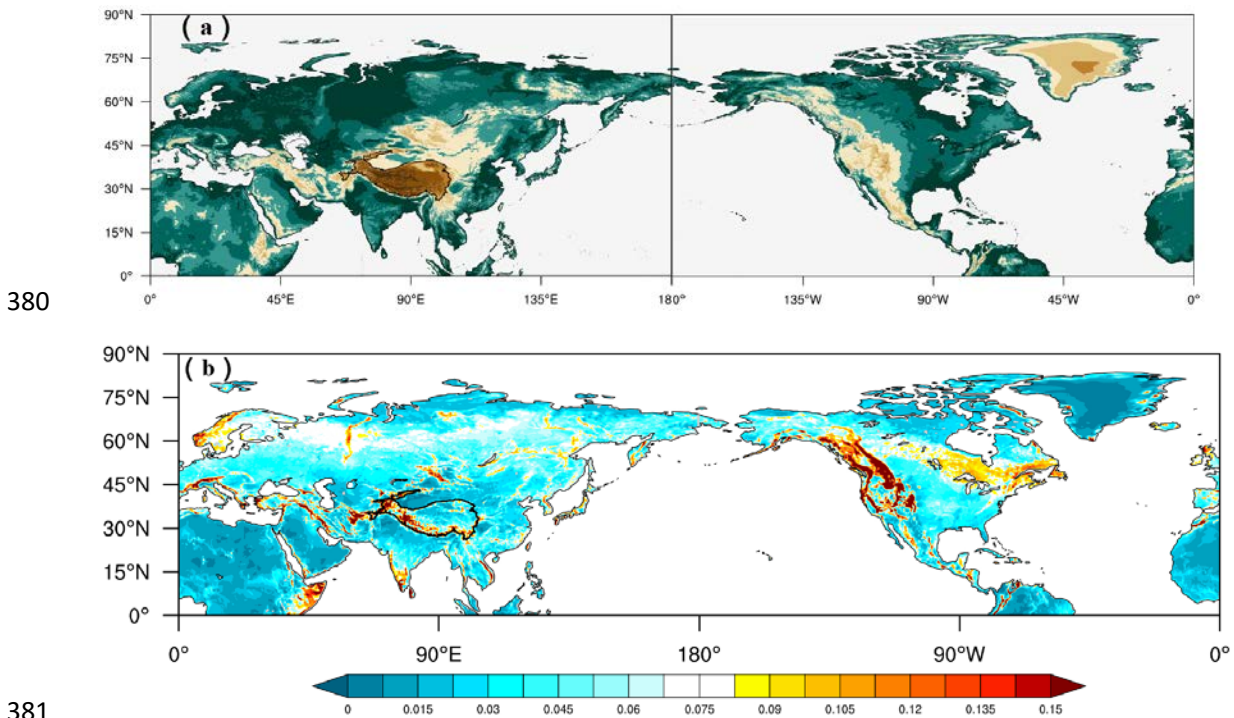

354 Figure 7 (d) shows the mean spatial distribution of PBLH – LCL in the Northern
 355 Hemisphere from June to August of 2010-2019. The TP (27-40N, 70-105E) and
 356 Rocky Mountains (27-40N, 103-120W) are two typical high value regions in the

357 Northern Hemisphere, and the mean PBLH – LCL over the TP and Rocky Mountains
358 are 376.7 m and -101.9 m, respectively.

359 Figure 7 (b)-(c) show the spatial distribution of ST and BT in the Northern
360 Hemisphere from June to August of 2010-2019, respectively. The effect of strong
361 thermal turbulence results in obvious positive value of PBLH – LCL at high elevation
362 regions under low air density conditions in the Northern Hemisphere ($BT = 0.008 \text{ m}^2$
363 s^{-3} , $PBLH - LCL = 376.7 \text{ m}$ over the TP and $BT = 0.011 \text{ m}^2 \text{ s}^{-3}$, $PBLH - LCL =$
364 -101.9 m over the Rocky Mountains). Figure 7 (b) also shows that there are strong
365 STs at these two high elevation regions ($ST = 0.087 \text{ m}^2 \text{ s}^{-3}$ over the TP and $ST = 0.085$
366 $\text{m}^2 \text{ s}^{-3}$ over the Rocky Mountains). Both the BT and ST increase significantly at high
367 elevation due to low air density compared to those at low elevation. The above results
368 enlighten us on thinking about whether the triggering effects of large topography and
369 boundary layer turbulence, which reflect the special turbulence characteristics in
370 boundary layer at high elevation regions under low air density conditions, can be
371 applicable for any large topography in the globe, including TP and other regions (e.g.
372 Rocky Mountains).

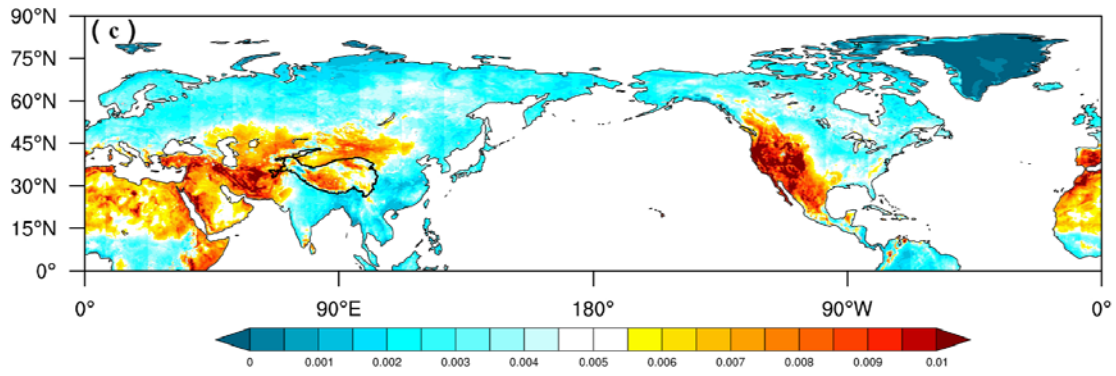

373 Figure 8 shows the conceptual model of atmosphere from the near-surface to
374 upper troposphere over the TP. Compared to the low elevation, the TP is characterized
375 by higher PBLH and lower LCL because of strong BT and ST, which is favorable for
376 the formation of shallow clouds in the afternoon. Meanwhile, the large scale
377 ascending motion over the TP results in the transition from shallow clouds to deep
378 convective clouds in the late afternoon and evening.

396 4 Conclusions and further discussion

397 In this study, we focus on the triggering effects of large topography and boundary
398 layer turbulence over the Tibetan Plateau on convection. The topography of the TP
399 also has a major role in the increased occurrences of convective clouds. Our results
400 further confirm the conclusions from Wang et al. (2020), which found that
401 PBLH-LCL over the TP is greater than that in eastern China. Compared to the eastern
402 China, with the same relative humidity, lower temperature over the TP results in a
403 lower lifting condensation level. With the same surface sensible heat flux, lower air
404 density over the TP results in a larger buoyancy flux and a deeper boundary layer. The
405 observational results show that, under low relative humidity condition ($RH < 40\%$),
406 the low cloud cover (LCC) is higher than 60% over the TP. In contrast, the high LCC
407 ($LCC > 60\%$) only appears under high RH condition ($RH > 60\%$) at low elevation.

408 In general, LCC increases with the increasing elevation. The median of LCCs at
409 high elevation (TP) is significantly greater than those at low elevation (eastern China)
410 throughout the day. The diurnal variations of LCC in eastern China are generally
411 distributed in unimodal pattern with the maximum appearing at 2:00 pm BT and low
412 values during the night. The diurnal variations of LCC at high elevation (TP) present

413 a bimodal curve with the maximum appearing at 5:00 pm BT and the secondary local
414 maximum appearing at 8:00 am BT. In addition, LCC maintains at high values at high
415 elevation (TP) during the day. The median cloud top height derived from himawari-8
416 retrieval product shows the transition from shallow clouds to deep convective clouds
417 in the late afternoon and evening over the TP, which is attributed to the strong
418 large-scale ascending motion from the near surface to upper troposphere over the TP.

419 The buoyancy term (BT) and shear term (ST) over the TP are significantly greater
420 than those at the low elevation, which is favorable for the increasing of PBLH.
421 Similar phenomenon occurs at other high elevation areas (e.g. Rocky Mountains). The
422 strong thermal turbulence results in positive value of PBLH-LCL at high elevation
423 regions under low RH condition in the Northern Hemisphere. The slightly greater
424 than zero PBLH-LCL corresponds spatially to increased LCC in the central part of
425 Rocky Mountains, but the obvious large-scale subsidence on both sides of the
426 mountain leads to strong inversion above PBL and lower RH in PBL, which further
427 lead to decreased LCC in these areas. Thus less LCC is generated at Rocky Mountains
428 compared to the TP.

429

430 **Data availability**

431 All reanalysis data used in this study were obtained from publicly available sources:
432 ERA5 reanalysis data can be obtained from the ECMWF public datasets web interface
433 (<http://apps.ecmwf.int/datasets/>). The satellite (CloudSat radar and Calipso
434 lidar)-merged cloud classification product 2B-CLDCLASS-lidar were obtained from
435 Colorado State University
436 (<http://www.cloudsat.cira.colostate.edu/data-products/level-2b/2b-cldclass-lidar>). The
437 himawari-8 retrieval products were obtained from JAXA Himawari Monitor
438 (<https://www.eorc.jaxa.jp/ptree/>).

439 **Code Availability**

440 The data in this study are analysed with MATLAB and NCL. Contact Y.W. for specific
441 code requests.

442 **Acknowledgements**
