Referee #01 Response

"Sources of Concentric Gravity Waves Generated by a Moving Mesoscale Convective System in Southern Brazil" by Nyassor et al.

The authors thank the reviewers for their insightful and constructive comments, corrections and suggestions. We implemented the comments, corrections and suggestions into a revised version of the manuscript. Please find our answers to the questions of the reviewers below, accompanied by the blue marked-up texts in the manuscript version. All major changes made due to the comments of RC 1 and RC 2 are highlighted in indigo.

Comment on acp-2022-267

Anonymous Referee #1

Referee comment on "Sources of Concentric Gravity Waves Generated by a Moving Mesoscale Convective System in Southern Brazil" by Prosper Kwamla Nyassor et al.,
---

In their manuscript "Sources of Concentric Gravity Waves Generated by a Moving Mesoscale Convective System in Southern Brazil", the authors combine measurements from multiple instruments at multiple altitudes with ray tracing models to connect gravity wave observations in the OH layer with their sources at the tropopause. Single cores of a moving mesoscale convective system are identified as most likely sources of the concentric gravity waves observed in the OH layer.

This work is quite impressive from the amount of data used and the analysis performed. However, I would suggest to better explain the reasoning behind all the measurements taken and the analysis performed. Both the introduction and the summary/conclusion section are missing clear scientific research questions motivating the work. At the moment the paper seems a bit like a data dump without a clear motivation behind. This impression could possibly be overcome by refining the introduction and conclusion. Additionally, I would suggest to revise all the sections/figures for their necessity to support the findings and possibly remove some of them.

Author response: We thank Referee #01 for the revision of the manuscript and constructive suggestions. We addressed the individual comments below.

A detailed list of minor comments is given below.

Comment #01: **L24:** Better: "in the tropical troposphere", as otherwise one might start arguing about the importance of orographic versus convective gravity waves.

Response There are several known sources of the GWs among which tropospheric convection - severe weather conditions such as thunderstorms are considered to be the most important and natural sources of AGWs in the tropical troposphere. ...... "tropical" is added.

Comment #02: **L27:** Maybe better: ... mechanism is known to generate concentric gravity waves ... (or remove at least "natural", you probably do not want to start a discussion about nonnatural GW sources).

Response Among these three, the mechanical oscillator (overshooting) mechanism is known to be one of the sources of concentric gravity waves (CGWs). .... "natural" is removed.

Comment #03: **L27:** Most [...] cases [...] have [...]

Response: Most tropospheric deep convection - CGWs cases in literature have other associated convection related phenomena, such as hailstorm (Yue et al., 2009; Vadas et al., 2012), lightning (Yue et al., 2014; Nyassor et al., 2021) and Transient Luminous Events (TLEs) (Boccippio et al., 1995; São Sabbas and Sentman, 2003; Sentman et al., 2003; Pasko et al., 2012) which are used as a measure of the severity of the thunderstorm. ..... "has" has been changed to "have".

Comment #04: **L38:** ... imgaes ... have been used ...

Response: Regarding the observation of tropospheric convective sources of GWs/CGWs, infrared images of cloud top brightness temperatures (CTBT) from satellite imagery have been used (Vadas et al., 2009a; Yue et al., 2009; Azeem et al., 2015; Takahashi et al., 2018; Figueiredo et al., 2018; Nyassor et al., 2021). ... "has" has been changed to "have".

Comment #05: **L42:** ray tracing models.

Response: Similar works by Vadas et al. (2009a), Vadas et al. (2012), Xu et al. (2015) and Nyassor et al. (2021) used ray tracing models to relate observed CGWs in OH emission altitude $\sim 87\,\mathrm{km}$ to overshooting top in CTBT images captured by the Geostationary Operational Environmental Satellites (GOES). .... ""model" has been changed to "models".

Introduction: You are nicely describing what was done before and what you are doing, but you are missing to describe the difference and provide a reasoning for your study. Why do we need this paper? What does it bring new to the world?.

Response: The introduction has been modified to explain the new things the paper bring in to the field.

Comment #06: **L101-103:** This is a hypothesis which will be confirmed later. Maybe rephrase: According to previous studies (...), the appearance of concentric structures in the airglow hints to: 1) point-like convective overshooting of the tropopause and 2) weak intervening background wind.

Response: According to previous studies (Vadas and Fritts, 2009; Vadas et al., 2009b; Yue et al., 2009), the appearance of the concentric structures in the airglow suggests; 1) point-like convective overshooting of the tropopause and 2) weak intervening background wind. .... The entire sentences has been rephrase.

Comment #07: L105: One parenthesis too much.

Response: The extra parenthesis has been removed.

Table 1: What is the exact definition of the propagation direction? Degree measured clockwise from North? And how do you define the propagation direction of a concentric outward propagating wave? Is only the value of the centre fit shown for the propagation direction?

Question a. What is the exact definition of the propagation direction?

For CGWs, they are expected to propagate in all directions. For this study, since we estimated the wave parameters along a specific direction, we only obtain one value. However, knowing that CGW propagates in all direction, we considered several propagations on the first visible concentric wavefront, then we estimate the wave parameters. Under weak wind condition, the parameters are expected to be similar, which is the case for these events. So, to give a general characteristics on the parameters of the wave, we compute the average for all the parameters obtained from each direction we considered. Hence, the propagation direction presented in Table is chosen arbitrarily for the ray tracing since the values obtained from all directions considered are similar. Based on your comment, we have explain this in the main text.

Question b. Degree measured clockwise from North?

Yes, the propagation direction is measured in degree clockwise from the North.

Question c. And how do you define the propagation direction of a concentric outward propagating wave?

As metioned in the response to the "a.", we determined the propagation direction for a single direction that we are computing the wave parameters. The propagation direction is determines as follows:

t_1 t_2 t_3 t_4 t_5
Conti...: As shown in Figure above, we apply discrete Fourier transform (Equation 1) to the regions in the selected time series images (labelled as t1,......., t5).

$$F(k,l) = \sum_{x=0}^{m-1}\sum_{y=1}^{n-1} e^{-i2\pi\left(\frac{xk}{m}+\frac{yl}{n}\right)} f(x,y) \tag{1}$$

Where $F(k,l)$ is the Fourier transform of the function $f(x,y)$, k, l, are the zonal and meridional wavenumbers, $M \times N$ is the dimensions of the analyzed image.

Next the cross-spectrum, $C(k,l)$ giving by Equation 2 was then estimated for each two successive time series images represented by $f(x,y)$ and $g(x,y)$.

$$C(k,l) = f(k,l)g^*(k,l) \tag{2}$$

Conti...: in which $C(k,l)$ is the cross spectrum between two successive time series and $f(k,l)$ and $g(k,l)$ represent the discrete Fourier transform, respectively. $g^*(k,l)$ represent the complex conjugate of $g(k,l)$ is the complex conjugate. The cross-spectrum was then average over the $n-1$ computed spectra.

We then computed the amplitude of the cross spectrum expressed by the modulus of the cross-spectrum (Equation 3),

$$|C(k,l)| \tag{3}$$

and the phase of the cross-spectrum express as

$$\varphi(k,l) = arctg\left\{\frac{Im[C(k,l)]}{Re[C(k,l)]}\right\}, \qquad -\pi \leq \varphi \leq \pi. \tag{4}$$

The determination of wave parameters $(\lambda_H, \tau, c_H, \text{ and } \phi)$ using cross-spectrum had been described by Maekawa (2000).
From the cross-spectrum:

   i. The zonal (k) and meridional (l) wavenumbers of gravity waves are the k and l corresponding to the maximum amplitude of the cross-spectrum;

   ii. Using the zonal (k) and meridional (l) wavenumbers, and the phase $(\varphi(k,l))$, the observed phase velocity is given by;

$$c_H = \frac{1}{\sqrt{k^2 + l^2}} \times \frac{\Delta\varphi(k,l)}{360°} \times \frac{1}{\Delta t}, \tag{5}$$

   where Δt is the time difference between two successive images

   iii. The horizontal wavelength λ_H of the wave was determined by

$$\lambda_H = \frac{1}{\sqrt{k^2 + l^2}}, \tag{6}$$

   iv. Next, the observed period of the gravity wave is estimated using:

$$\tau_H = \frac{\lambda_H}{c_H}, \tag{7}$$

   v. Finally, the propagation direction of the wave can be determined from

$$\phi = tan^{-1}\left[\frac{l(l_{max})}{k(k_{max})}\right], \tag{8}$$

   where k_{max} and l_{max} are the maximum wavenumbers in the x and y directions.

Continuation:

d.   Is only the value of the centre fit shown for the propagation direction?

Yes, it is. However, we would like to mention that the center fit is an a approximation, considering zero wind, but for the only ray path shown is for only a chosen value as described in (a).

Figure 2:   (+ description): Maybe do this as an example on top of one of the plots from Figure 1, so one can better understand what you are doing. Maybe explain the crest/trough part already at point 1. Makes it easier to follow. In 2: The 3 circles have to have the same radius, no? In 5: Why so complicated? Why not directly measure from P to where one of the lines from 3 crosses the black circle? Are all these steps done manually for each case or is there an automated software?

(a.) The 3 circles have to have the same radius, no?

Yes, the 3 circles in this case have the same radius.

(b.) In 5: Why so complicated? Why not directly measure from P to where one of the lines from 3 crosses the black circle?

It appears a bit complicated here because, we are trying to give details on our approach and also because we are using three circles in this case, care is taken in order to accurately verify the computation.

(c.) Are all these steps done manually for each case or is there an automated software?

Yes, please, we have developed a software to automatically run the computation. We only need the three initial positions of the three (3) centers as inputs.

Based on your comment the description here has been modified to simlify version in the main text as shown below.

Chapter 2.1: Ray tracing part: How is the vertical wavelength/wave number determined, which is necessary for the raytracing? All 4 stopping criteria seem a bit arbitrary. Can you explain in more detail why you chose these four stopping criteria? What is the physical reasoning behind each of them?.

- How is the vertical wavelength/wave number determined, which is necessary for the raytracing?

  The vertical wavelength/wave number was determine along the ray path at each step. However, Equation 3 (dispersion relation) in the main text has some conditions imposed. This restriction causes the dispersion equation to reduce to

  $$\omega_{Ir}^2 = \frac{k_H^2 N^2}{m^2 + k_H^2 + 1/4H^2},\tag{9}$$

  when dissipation is negligible (Gossard and Hooke, 1975) below the turbopause. Equation 3 is the dispersion relation for a GW in the presence of molecular viscosity and thermal diffusivity.

All 4 stopping criteria seem a bit arbitrary. Can you explain in more detail why you chose these four stopping criteria? What is the physical reasoning behind each of them?

- Since a GW propagates at the group velocity, this ray tracing is constrained to permit GWs propagating slower than the speed of sound, $c_g \leq 0.9c_s$, where the factor 0.9 is arbitrarily chosen. Here $c_g = \sqrt{c_{g_x}^2 + c_{g_y}^2 + c_{g_z}^2}$ is the group velocity in the wave propagation direction. This condition is set to remove spectrum of acoustic waves.

- When a GW encounters a region in the atmosphere where the horizontal phase velocity is exactly equal to the horizontal wind speed, the GW approaches a critical level or absorption level. Physically, the vertical propagation of the wave becomes very slow, thereby causing the wave not to propagate horizontally because $m \to \infty$. In this condition, the intrinsic frequency of the wave approaches zero in this region causing the wave to be rapidly absorbed by the atmosphere. Therefore, for the ray tracing to calculate the wave trajectory, it is necessary for the intrinsic frequency of GW to be greater than zero ($\omega_{Ir} > 0$).

Chapter 2.1:

- As GWs propagate higher into the thermosphere, molecular viscosity and thermal diffusivity become an important dissipative process owing to the decrease in density with altitude. This causes an increase in the momentum flux of GWs in the lower thermosphere until it reaches a maximum value and then begins to decrease rapidly with increasing altitude. This, therefore, implies as GWs attain their maximum momentum flux, they tend to dissipate. Hence, it is necessary for the momentum flux along a GW ray path must satisfy $R_m > 10^{-15}R_0$. R_m is the momentum flux at each altitude and R_0 is the momentum flux at the reference altitude. The factor 10^{-15} was arbitrarily chosen.

- The vertical wavelength needs to be smaller than the viscosity scale, to ensure that the viscosity will not change too much in time and altitude, that is, $\left[|\lambda_z| < \frac{2\pi}{\frac{d\nu/dz}{nu}}\right]$, Here, $\nu = \mu/\rho$ is kinematic viscosity with μ being molecular viscosity and ρ the density (Vadas, 2007). This condition is necessary because GWs with these characteristics must satisfy the imposed simplifications (slowly varying parameters) to obtain the dispersion relation.

- Based on your comments, this aspect of the manuscript have been modified to include this comment.

The advantage of this ray-tracing method (variable background wind over this large altitude range) should be made clear somewhere in the text.

This model is used to study the propagation of GWs relative to variable background wind in the atmosphere and to determine the possible source location. The propagation of GWs in the presence of background wind enables the investigations of the effect of the wind on the wave.

Comment #08: **L186ff:** Please reorder for better readability:

Response: "Adapting Equation 3, the overshooting top height (OT_{Height}) from Griffin et al. (2016), the overshooting tops (OT) were estimated using the brightness temperature (BT) of the OT, the tropopause height and temperature" has been modified to:

Adapting Equation 3 from Griffin et al. (2016), the overshooting top height (OT_{Height}) is estimated using the brightness temperature (BT) and the lapse rate (LR) of the overshooting top (OT), the tropopause height and temperature.

$$OT_{Height} = H_{Trop} + \frac{OT_{BT} - T_{Trop}}{OT_{LR}} \qquad (10)$$

Here H_{Trop} is the tropopause height, OT_{BT} is the brightness temperature of the OT, T_{Trop} is the tropopause temperature and OT_{LR} is the OT lapse rate.

The cloud top brightness temperature was obtained from the Advanced Baseline Imager (ABI), which is an imaging radiometer of GOES-R satellite. The ABI has 16 different spectral bands, including two visible channels, four near-infrared channels, and 10 infrared channels with a spatial resolution of 0.5 - 2 km. Among the weather and climate products of these channels, the CTBT product is derived from the 11, 12 and 13.3 μm infrared observations.

The OT lapse rate was estimated using the radiosonde profile and the CTBT. The OT lapse rate for the days considered in the determination of the tropopause temperature and altitude were averaged and was found to be -7.35 Kkm^{-1}.

Comment #09: **L160:** Why do you state this here, as you are not tracing any waves forward to the thermosphere?

Response: We mentioned it here just to emphasize the fact that these two conditions are not the most important stopping conditions within the altitude range considered.

Comment #10: [...] regions have been used to identify [...]

Response: **L220:** "[...] regions has been used to identify [...]" has been changed to "[...] regions have been used to identify [...]".

Comment #11: **L221 & 222:** I am confused by the use of references in this sentence. Why are you referencing other papers for things you have done here in your paper?

Response: There references were giving because, we intend to give credence to previous work. Base on the comments, the sentence on L221 & 222 has been modified to:

The coldest regions has been used to identify convective overshooting tops (Bedka et al., 2010; Jurkovic et al., 2015) and the possible source of the CGWs (Nyassor et al., 2021 and reference therein).

Comment #12:   **L231:** Maybe better "deployed"

Response: We have change the word "employed" to "use".

Figure 6:   The description of the different colours and vectors belongs to the caption, not the text.

Response: The regions where wave propagation is not permitted (forbidden region) due to the characteristics of the wind in the troposphere correspond to the wind from 0 - 17 km (red rings). Between the tropopause and mesopause (light blue rings), the wind between 18 and 87 is presented, whereas above 87 to 100 km, the wind are shown by the green rings.

The description of the different colours and vectors has been included in the caption as:

Caption description: The wind characteristics from 0 17 km is represented by red rings, from 18 - 87 km by light blue ring and above 87km by green rings.

Comment #13:   **L258f:** If this criterion is not applicable to the cases you show, why do you introduce it?

Response: We have modified this part of the text, taking into consideration your comment.

The waves observed here have phase speed sufficiently large that the winds below do not introduce major distortions in the wave fronts and that they hence can be still recognized as concentric wave structures.

Comment #14:   **L284:** Maybe use "shown" instead of "demonstrated"?

Response: "demonstrated" has been changed to "shown"

Comment #15:   How is the CAPE calculated?

The CAPE can be estimated using

$$CAPE = \int_{p_f}^{p_n} R_d(T_{vp} - T_{ve})dInp \tag{11}$$

where T_{vp} is the virtual temperature of a lifted parcel moving upward moist adiabatically from the level of free convection to the level of neutral buoyancy, T_{ve} is the virtual temperature of the environment, R_d is the specific gas constant for dry air, p_f is the pressure at the level of free convection, and p_n is the pressure at the level of neutral buoyancy.

Source: https://glossary.ametsoc.org/wiki/Convective_available_potential_energy

Comment #16: **L290ff:** Is this an observation from your data or from Kim et al.? I would suggest to rephrase: It was observed in previous studies that the presence of deep convection with colder cloud tops brightness temperatures further decreases the tropopause temperature (Kim et al., 2018). In our data this also happens between 12:00 UT on September 30, 2019, and 12:00 UT on October 3, 2019, when the cloud top temperature ranges between -40°C to -90°C.

Response: Is this an observation from your data or from Kim et al.?

Yes, this is an observation form the data we used in this work, the temperature profile from radiosonde and radio occultation, and cloud top images from GOES-16.

Your suggestion has been considered in the main text.

Comment # 17: Reorder **Figures 10 & 11** according to their first mentioning in the text.

Response: Due to the comment of the RC1, this entire section has been modified.

Comment # 18: **L315ff:** Please rephrase. The first and second sentence seem to be in contrast to each other. Were all four cores there or only core 3 & 4?

As mentioned in the previous comment, the entire section on the tracking of the convective cores in space and time have been re-written due to the commments and suggestions of RC1.

Comment #19: **L344 - 355:** Please explain better where you get the diameter of the plume at the tropopause from (31 km you state, but not where you extracted this value from).

Response: The explanation of the estimate of the plume diameter is given below. This is the new/modified version of the previous explanation.

This radius is the same as the radius of the first visible concentric structure in the OH images. The vertical dotted line indicates the height of the cone. The red horizontal solid line indicates the diameter of the tropopause, and the black and white vertical slanted dashed lines extending vertically at either side of the dotted line are used to demarcate the propagation of the CGWs above the tropopause after the overshooting of the tropopause. To determine the tropopause diameter, the concept of a conical propagation configuration of CGWs was used Vadas et al. (2009b); Nyassor et al. (2021). The base of the cone with a radius (same as the radius of the CGWs) of 154 km was set at an altitude of 87 km. We then followed the slant heights of the cone, thereby determining the radius at each kilometer until we reached the vertex of the cone. The vertex of the black and white dash line-slanted path is above the tropopause. The radius at the tropopause (i.e., the red horizontal line in the right panel of Figure 10) is ∼31 km (diameter of ∼62 km).

To approximate the diameter of the tropopause, the diameter of the convective plume was considered. According to Vadas et al. (2009a, 2012), a typical diameter of a convective plume is 15 - 20 km. So, we take into account the dome-like protrusion shooting from the highest overshooting point to the anvil of the cloud. Then, we set a theshold of 70°C and constructed a circle with a radius 31 km around the pixel with the coldest CTBT. The 70°C threshold was set because it was observed that other protrusion do originate from CTBT within this BT range within every 10 min. So, to restrict the selection of OTs to the maximum spatial resolution of 2 km plus ∼4 km (two extra pixel), we set the diameter of the overshooting region to be the diameter of the plume at the tropopause. The determination of the plume at the tropopause is important because it is used approximate possible regions within which overshootings are most likely to occur.

Chapter 3.4: This chapter seems a bit like unnecessary information to me. Please either remove or explain why it is necessary for your findings (e.g. mention it in the summary section).

Response: This events are presented in the current work to give emphasize to the severity of the convective activity before, during, and after the wave events presented.

Comment #20: **L441:** Is signifies the correct word here?

Response: I guess "indicates" would be the correction word here. So "signifies" has been changed to "indicates".

Comment #21: **L482f:** spectra (plural) − > were

Response:	The entire Section 3.5 has been removed.

Figure 15:	Please use a more intuitive colour scale for a continuous (not around 0 centred) range. See also Crameri, Shephard, Heron (2020) for hints on good colour scale usage.

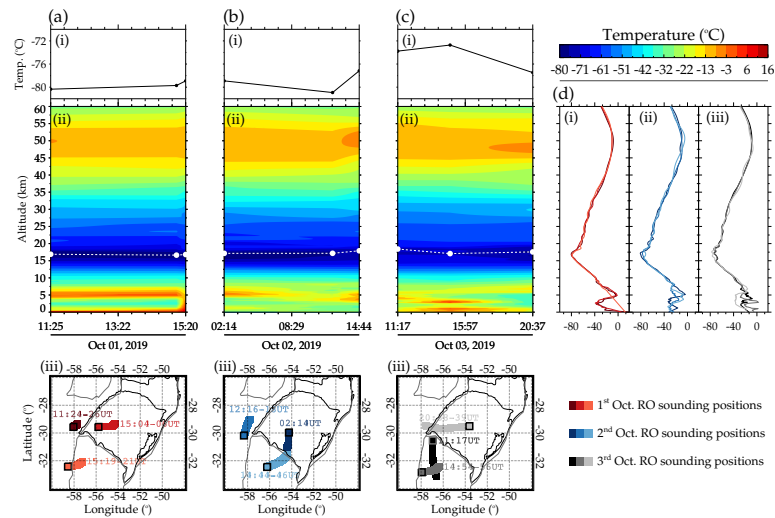
Response:	To L482 & Figure 15.
	As a result of the comments and suggestions in RC1, the entire Section 3.5 has been removed.

Comment #22:	**L524:** *Rossby*

Response	"Rosby" has been changed to "Rossby"

Figure A1:	For better comparability, the colour scale (extend) for the upper plots should be kept constant. Additionally, please add an x-axis. Otherwise the points in the lower panels are really hard to interpret. Is the tropopause here defined by thy laps rate?

Response:	Thanks very much. Please, the modified plot is shown below:

Figure A1:


- Is the tropopause here defined by thy laps rate?

Yes, please. We estimated the tropopause using both the cold point criterion and confirmed it using the lapse rate criterion.

Comment #23: Please check citation formatting throughout the whole manuscript.

Response: The citation formatting had been checked throughout the manuscript and the neccessary correction had been implemented.

Referee #02 Response

"Sources of Concentric Gravity Waves Generated by a Moving Mesoscale Convective System in Southern Brazil" by Nyassor et al.

The authors thank the reviewers for their insightful and constructive comments, corrections and suggestions. We implemented the comments, corrections and suggestions into a revised version of the manuscript. Please find our answers to the questions of the reviewers below, accompanied by the red marked-up texts in the manuscript version. All major changes made due to the comments of RC 1 and RC 2 are highlighted in indigo.

Comment on acp-2022-267

Anonymous Referee #02

Referee comment on "Sources of Concentric Gravity Waves Generated by a Moving Mesoscale Convective System in Southern Brazil" by Prosper Kwamla Nyassor et al.,
Atmos. Chem. Phys. Discuss., https://doi.org/10.5194/acp-2022-267-RC1, 2022

The paper presents a thorough analysis of concentric GW patterns in the middle atmosphere and deep convection as a potential source. The investigation methods are sound and the figures of generally high quality. Much emphasis is given to the development of the convection in the potential match time and how large an emission area and match error might be. This distinguishes the current work from previous studies and I recommend to publish the current study for ACP. However, I think that the structure of the paper needs to be improved. In particular, the MCS tracking analysis is never shown together with actual brightness temperatures, which would elucidate which structures are actually tracked. Some real zooms would be helpful, so the details close to the source can be distinguished. There are quite a number of repitions (please remove), but sometimes a motivation why the next step in the analysis chain is performed whould be helpful.

Author response: We thank Referee #02 for the revision of the manuscript and constructive suggestions. We addressed the individual comments below.

Major comments:

The presentation logic needs to be improved. The tracking data are shown on several figures, but never become really clear. My suggestion would be:

Introduction: Please sketch your multi-step approach: a) back-traces, b) coparision with instantaneous map c) area region + tracking → likelihood for a specific convective event / MCS in short. Do so without providing results but refer to (sub)sections. Then one gets a plan of what you are going to do

Response:
Figure 1: A 3D diagram showing a multi-step process of concentric gravity waves from the generation in the troposphere to the observation in the mesosphere.

The description of Figure 1 has been given in Section 1.1 in the main text.

Figures 3 - 6:   a) remove the inlay showing the tracking b) add a new panel showing a real zoom of the core circle with the RT and the symbols, use red and blue for the respective tropopause crossing of the ray.

We thank for this comments and suggestions. We updated Figures 3 - 5 accordingly and included it into the main text as Figure 4. We further redefined the symbols used to represent the OTs for better visibility. The respective tropopause crossing positions of the model and zero wind ray paths have been represented by the colors of the ray paths.

Comment # 01:   Do a new combined Figure where you show for one fixed time the BT -90 → -50°C, the tracking position at this time with a larger symbol and the tracks for the other time with smaller symbols. For a second panel of each wave-event: Combine this with tracks overalyed on winds as in F11. For the tracks the area of the circle / zoom region is sufficient and this would allow to resolve the movements. The large area including the observation side is not required, on the other hand.

Response: The plots of the tracking have been modified to include the fixed time the BT -90 → -50°C, the tracking position at this time with a larger symbol, and the tracks for the other time with smaller symbols.

Continuation: However, instead of just one figure for a wave event, we rather used this approach for the OT at each 10 mins cloud top brightness temperature (CTBT) image with the OT corresponding to the time frame represented by a large symbol. To differentiate the symbol to that time from other time, an open version of the symbol are used.

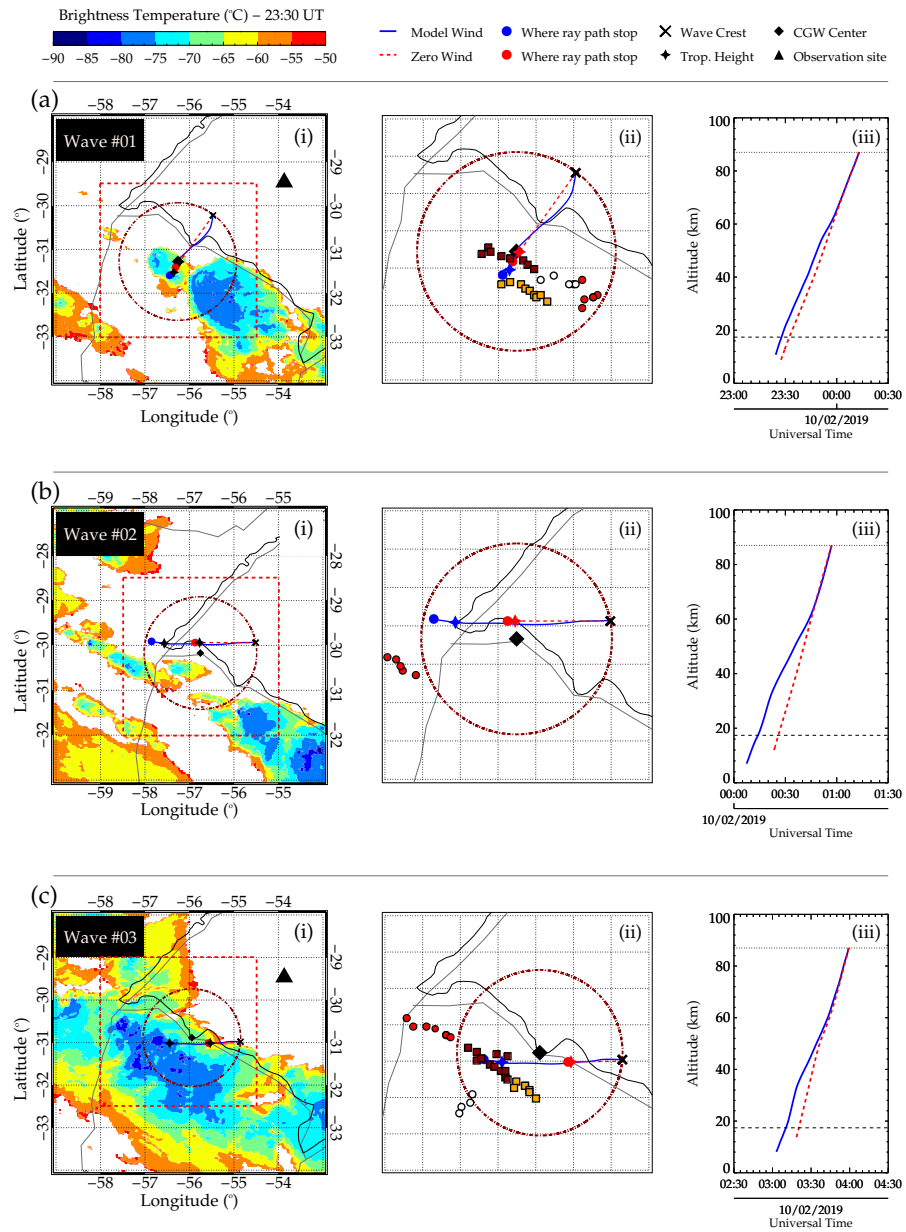
Figures 4:


Figure 4: Ray tracing results of concentric gravity wave (CGW) events one (#01), two (#02), and three (#03) on October 1 - 2, 2019.

Conti.: For squares (circles), closed squares (circles) are used the OTs not corresponding to the time of the CTBT, whereas the large open square (circle) for the OT at the time of the CTBT. As a result of these modifications: twelve (12) and nine (9) different subplots, were made for the Waves #01 and #03, and wave #02 to explicitly tracked the OTs.

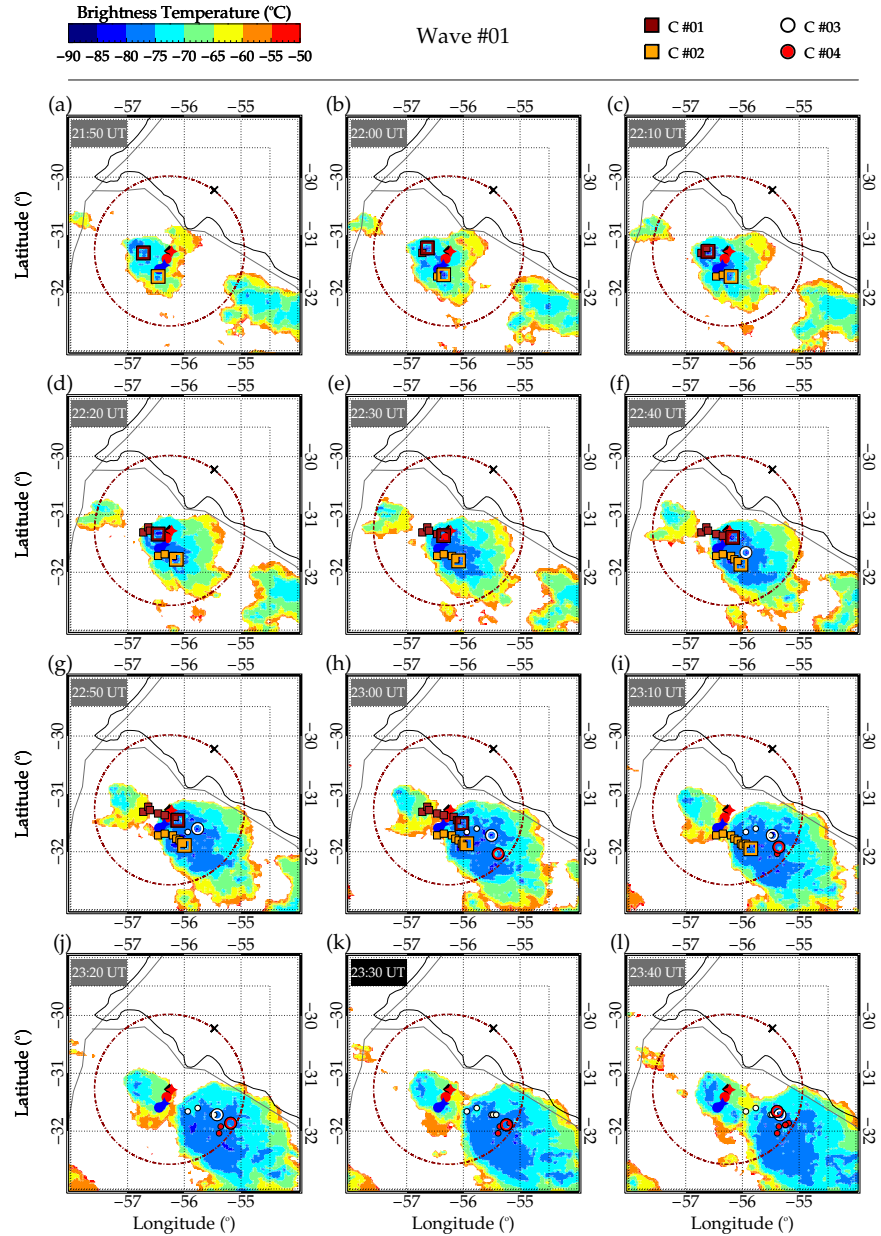
Tracking OTs: Figure 12 shows the OTs tracked in space at 10 mins CTBT time stamp.


Figure 12. Tracking of the individual convective cores / overshooting tops (Cs #01, #02, #03 and #04) in space and time for Wave #01.

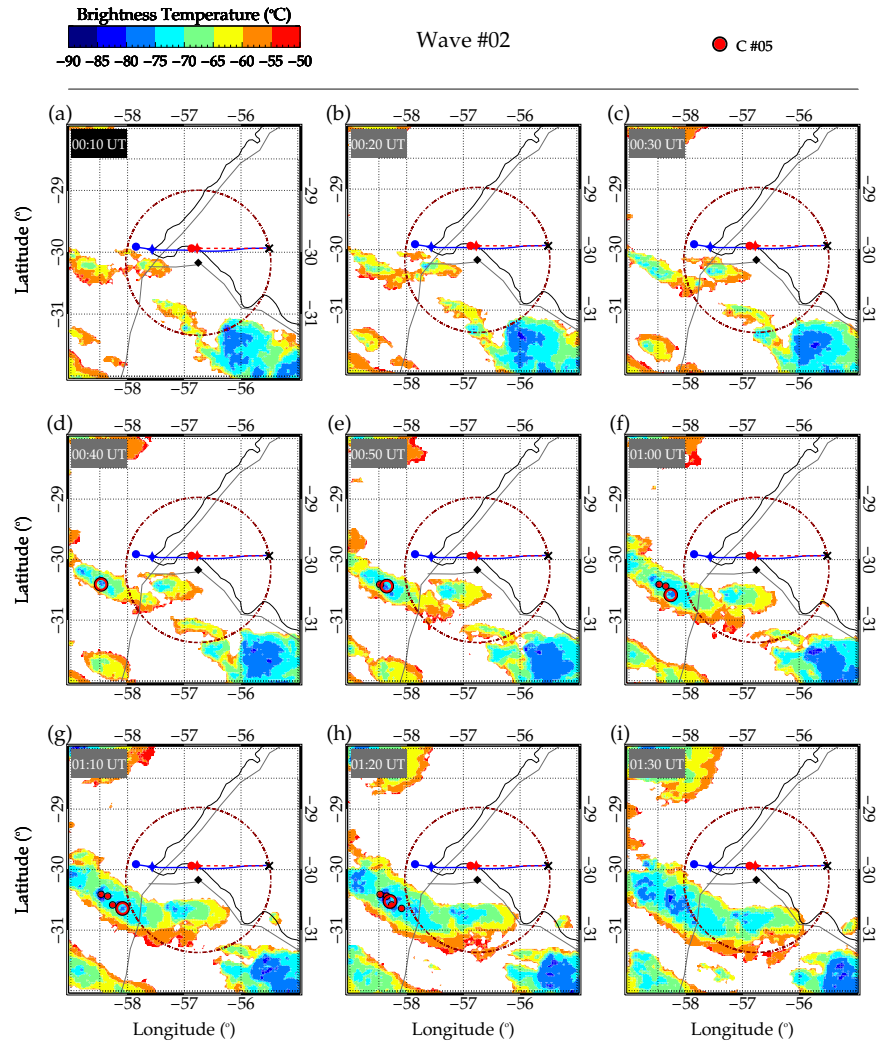
Tracking OTs: Figure 13 shows the OTs tracked in space at 10 mins CTBT time stamp.


Figure 13. Tracking of the individual convective cores / overshooting tops (C #05) in space and time for Wave #02.

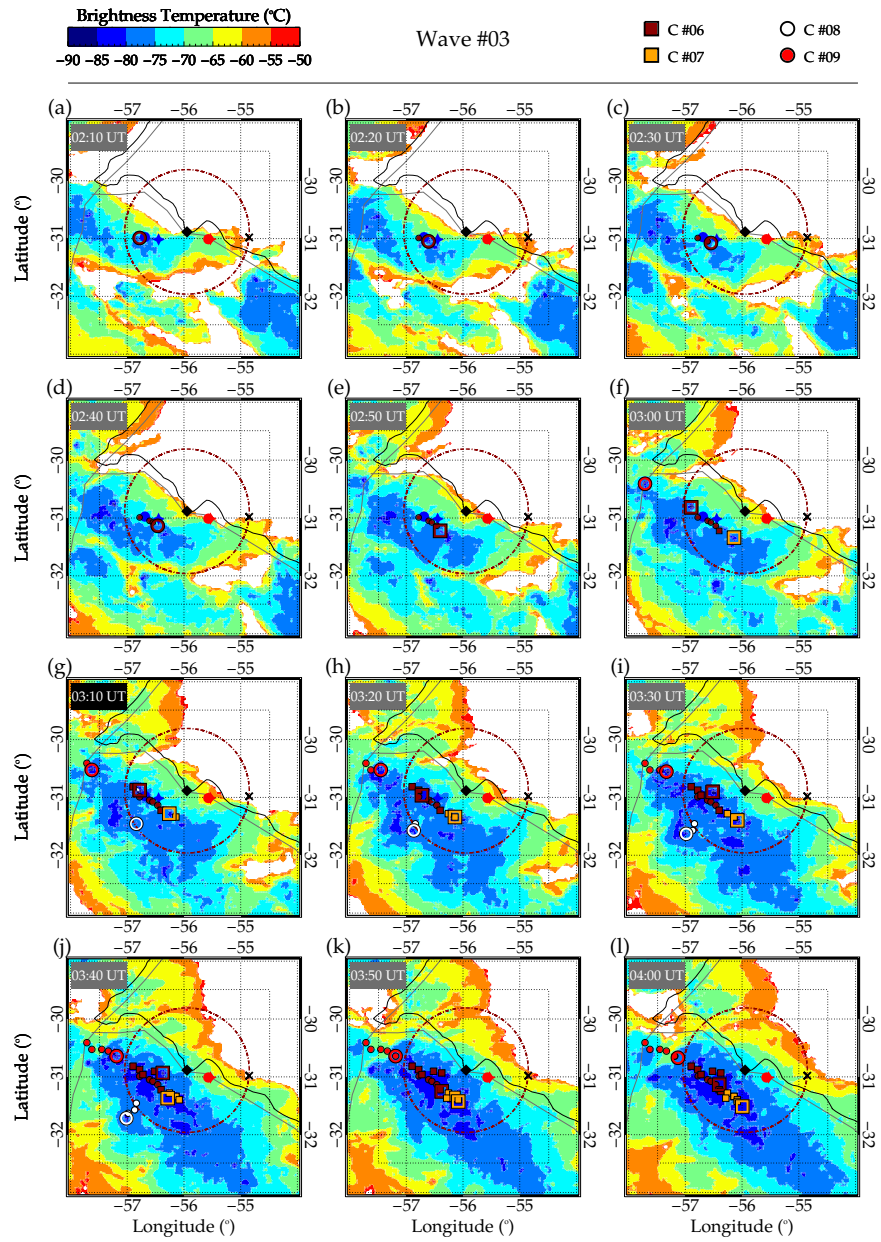
Tracking OTs: Figure 14 shows the OTs tracked in space at 10 mins CTBT time stamp.


Figure 12. Tracking of the individual convective cores / overshooting tops (Cs #06, #07, #08, #09) in space and time for Wave #03.

Comment #02:   For the tracking run from C #01 to C #09, don't repeat C #01 - #04 for the second / third event. Then it becomes immediately clear that these are not the same!

Response: The OTs tracked throughout the text have been labeled from #01 to #09. These changes are implemented for both the tracking of the OT in space (in Figures 12, 13, and 14) and time (Figure 10) as well.

Conti...: In Figure 10, the time corresponding to the highest OTs is represented by the open squares (circles). Similar symbol connotations are used to aid the comparison between the highest overshooting top in space and time.

Tracking OTs: Figure 10 shows the OTs tracked in time at 10 mins CTBT time stamp for the three (3) CGWs (Waves #01, #02, and #03).
Figure 10. Tracking of the individual convective cores / overshooting tops (i.e., Cs #01, #02, #03, #04, #05, #06, #07, #08, and #09) in time for Waves #01, #02, and #03.

Comment #03: **Summary:** Please provide a more generic summary. Describe the new points of your method (combing RT and tracking, error estimates) first. Briefly summarize what you found.

Response: The findings of this method have been described in the summary/conclusion in the main manuscript. Also, in the introduction, a brief description of the method has been given based on the comment of the Referee #01.

Comment #04:   More to the details of the writing: You quite often present a result in something like two sentences where you don't have the details. One or two paragraphs later you then explain this. That is unhelpful, becuase one gets sidetracked. Rather than having preliminary results a motivation at the head of the section where you are in the general plan would be helpful.

Response: Thank you very much for this comment. Due to this comment, the entire result and discussion section have been rewritten in order to have a flow in the presentation of the results and discussion. Also, the order in the presentation has been changed according to the order of occurrence of the CGW events. For the OT tracking in time, we presented this section to first demonstrate the overshooting extension and also to verify if significant overshooting top place. The tracking in space then follows afterward.

Section 3.5

There are several problems with this section:

Comment A):   The observational filter of GPS-RO allows only to see GWs with wavelengths larger than ~ 100 km, actually even longer than $200\text{-}300$ km for the fast waves discussed here (cf. comments to LL170 below). That is for along-LOS wavelength, still one would need a very favorable viewing geometry to see the waves. As every MCC also emits longer horizontal scales it is much more likey you sound these (cf. horizontal wavelengths of GWs determined from AIRS). This makes the approach faulty from the beginning.

Comment B):   Which vertical wavelengths did you determine? They are not shown! Are they compatible with the extremly high phase speeds you gain directly from the OH observations. At least at the OH layer they must be long ($\lambda_z > 15\,km$) or you couldn't observe the waves from an OH layer. In the stratosphere refraction by the background wind is negligible (your own argument), thus they the GWs have long λ_z their, too. In that case you need to spedify how you sepeareted between GWs and background.

Comment C):   A lot is missing in the descrition. What did you take for the propagation direction? Radial from a center would be my approach ...

This section does not contribute much to the overall results. Thus I suggest to simply remove section 3.5 from the paper rather than trying to fix the points.

Response: Thank you very much for this comment. As suggested, we have removed this section from the manuscript.

Specific comments:

Comments #01: **L257:** Please omit or reformulate the statement: "It is worth ... " Convective GWs can have a wide range of phase speeds. Considering previous works by Hye-Yeong Chun and Joan Alexander you would assume the spectrum to peak at phase speeds of 20 - 30 m/s. Actually, such lower phase speed CGWs drive the QBO. Therefore, the statement must not be made in such generality. I would rather say, the waves observed here have phase speed sufficiently large that the winds below do not introduce major disturbances in the wave fronts and that they hence can be still recognized as concentric wave structures.

Response: Based on your comment, your suggestion has been used to replace this text: "The waves observed here have phase speeds sufficiently larger than the background wind and do not introduce major distortions in the wavefronts. So they can still be recognized as concentric wave structures".

Comments #02: In all maps: You show circles in lon/lat. Shouldn't it be circles in terms of (km)? So close to the tropics the difference is only 15%, still ....

Response: All circles are indeed in km on the maps. We showed them in degrees because of the unit of the axes of the plot. However, the equivalence is given in kilometers in the main text.

Comments #03: **Fig 10 and description:** This repeats a lot between legend and text, but it does never become really clear to me what you are after. Please try to reformulate. In particular, it is not the tropopause diameter, but the diameter of something at the tropopause and it remains unclear to me whether you try to estimate backward from the observed rings or forward from the source or both.

Response: The description of of Figure 10 has been rewritten to give a detail explanation to the why the tropopause diameter was introduced in this work.

Minor comments and technical corrections:

Comments #01: **L23** of the GWs → omit the

Response: "the" has been omitted.

Comments #02:   If you consider it from the view point of the mesosphere - otherwise mountain waves are probably more important and spontaneous imbalance for higher latitude of similar importance

Response: Thanks for the comment. The sentence has been rewritten to factor in the suggestion as: "There are several known sources of mesospheric GWs among which tropospheric convection - severe weather conditions such as thunderstorms are considered to be the most important and natural sources of AGWs in the tropical troposphere."

Comments #03:   **L27:** has → have

Response: "has" has been changed to "have".

Comments #04:   Since you give a quite comprehensive overview, perhaps add something of the following:
There are also some studies linking satellite observations with OLR. That includes work by McLandress et al., JGR, 2000, Jiang et al., JGR, 2004 for MLS, Choi et al 2009 (introducing a CGW source model), Preusse et al. 2001 (IR limb sounding). Also, a typhoon may act as a source to quasi-circular waves of much larger scales → Kim, Chun and Wu, JGR, 2009).

Response: In the introduction, as mentioned, OLR and MLS observations have been reviewed. Literature review on typhoon being a source to quasi-circular waves have as well been included.

Comments #05:   **L74 - L75:** repeats 1024 pixels.

Response: The repeated "1025 pixel" have been removed.

Comments #06:   **L105:** this is horizontal and time? Please say so

Response: This has been implemented as "The spatial (horizontal) and temporal wave parameters .... " in the main text.

Comments #07:   Equations 1 & 2. This would be more meaningful if you also provide the dispersion relation

Response: The dispersion relation has now been provided in the main manuscript.

Comment #08: **L144:** Omit the sentence The backgrounds ... That's coming in the next paragraph comprehensively.

Response: The sentence "The backgrounds (i.e., wind and temperature) were concatenated within 65 - 75 km of altitude" has been removed.

Comment #09: What does happen, if you have a bias? A potential bias could induce a locally enhanced / reduced buoyancy frequency. Would it be worth correcting for that first?

Response: As you rightfully said, bias could induce a locally enhanced/reduced buoyancy frequency. The correction has been implemented.

Comment #10: **L155:** Since you use this as stopping condition: What is your actual conserved quantity? In GROGRAT it would be wave action flux.

Response: For this model, the the real component of the observed frequency ω_{Ir} remains constant along a ray's path provided the unperturbed background variables are independent of time (Lighthill, 1978, Vadas et al., 2005).

Comment #11: **L158:** module → sounds a bit strange, simply omit?

Response: "module" has been omitted as suggested.

Comment #12: **L164:** I am missing the point of the "Therefore". You mean unusual cold so you want to see whether both lead to the same deviation?

Response: Exactly. The reason for both methods is for verification. The section of the paragraph containing this information in the main text has been modified to clarify this.

Comment #13: **L167/169:** repeats

Response: The repeated sentence has been removed.

Comment #14: **L170** With that you very likely see different horizontal wavelengths than the ones you find in the airglow. The observational filter of GPS is given in:

@Article{lange_2003,
Author = "M. Lange and Ch. Jacobi",
Title = "Analysis of gravity waves from radio occultation measurements",
Journal = "Springer Berlin",
Pages = "479-484",
Year = 2003
}

They actually come to the same values as found by the analytical approach in Preusse et al. JGR 2002. With that you need very favourable viewing conditions (angle between LOS and wave fronts) to see the same wave. More likely you are observing longer parts of the wave spectrum emitted from the same event.

How did you remove the large-scale background in the GPS profile?

Response: A Savitzky-Golay high-pass filter was used. However, based on your comment in the major comment on **Section 3.5**, every aspect of the radio occultation has been removed besides the temperature profile used to verify the tropopause temperature variations in radiosonde observation.

Comment #15: **L177** That sentence is a bit ambigious. Do you mean: A large overshoot results in a particular cold tropopause? Or do you mean: If the tropopause is already particularly cold you need more energy to create an overshooting? Please insert one more sentence making this more specific.

Response: We meant to say that the tropopause is already particularly cold so more energy is needed to create an overshooting. As suggested, a sentence has be inserted to give more specifc interpretation to the preceding sentence.

Comment #16: **L203:** Why $T_{core}/2$ and not $\Delta T_{core}/2$?

Response: In this case, the T_{core} does not change for an image. So, in this estimation, the T_{core} is held constant while the $T_{core}/2$ is computed. It is important to mentioned that the determination of the T_{core} is based on ΔT. The T_{core} is an index used to determine the pixel with their temperature scale.

Comment #17: **L220** regions have been

Response: "regions has been" has been changed to "regions have been"

Comment #18: **L237 Suggestion:** The blocking diagram hence visualizes where the background winds induces a zero vanishing intrinsic frequency of the GWs.

Response: The suggestion given above has been included in the main text.

Comment #19: **L243:** I like the 3D blocking diagram as it shows the altitude structure, but swap introduction of 6b and discussion of phase speed: the quantitative argument is much better seen from 2D. (Or reading further, just omit the in-advance statement L244).

Response: Based on your comment, the position of the Figure 6 in the previous version of manuscript, now Figure 7, the 2D projection of the blocking diagram has been change to suit the text.

Comment #20: **L265:** There is Taylor and Hapgood (1988) as well (please include, it's the first) - and then I think you have the full list. Maybe "Numerous" is a bit strong. Anyway, you here repeat from the introduction.

Response: Taylor and Hapgood (1988) has been cited in the main text as suggested. Also, the introduction to this section has been modified to remove the repetition.

Comment #21: **L277:** That sentence is too long and too warped.

Response: The sentence has been simplified in the main text.

Comment #22: **Figure 10:** Diameter of the tropopause: what do you mean? diameter of circular wave fronts at tropopapuse altitude? Diameter of overshooting?

Response: Here "diameter of the tropopause" is the estimated diameter of the tropopause defined to be the region within which a possible overshooting may occur. The diameter of circular wavefronts at tropopause altitude is the diameter the CGW is supposed to have at the tropopause since CGWs have a conical propagation. In the case of "diameter of overshooting", it is the diameter of the overshooting region (i.e., the diameter of the coldest CTBT captured by GOES).

Comment #23: **Figure 11** You don't need three grey-scale bars, only information is time.

Response: Thank you for the suggestion.

Comment #24:   **L353:** Take your own values! You should be able to just take them out of e.g. Figure 7.

Response: Thank you for the suggestion.

Comment #25:   **Literature:** For backward ray tracing: Some work by Pramitha?

Response: Yes. Pramitha used backward ray tracing to show evidence for tropospheric wind shear excited GWs.
