23 **Abstract.** Here we present a field measurement of ClNO<sub>2</sub> (nitryl chloride) and N<sub>2</sub>O<sub>5</sub> (dinitrogen  
24 pentoxide) by a Time-of-Flight Chemical Ionization Mass Spectrometer (ToF-CIMS) with the Filter  
25 Inlet for Gas and AEROSols (FIGAERO) at a regional site in Pearl River Delta during a  
26 photochemical pollution season from Sept. 26<sup>th</sup> to Nov. 17<sup>th</sup>, 2019. Three patterns of air masses are  
27 sampled during this campaign, including the dominating air masses from the north and northeast  
28 urban regions (Type A), the southeast coast (Type B), and the South China Sea (Type C). The  
29 concentration of ClNO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> were observed to be much higher in Type A and B than those in  
30 Type C, indicated in Type C, indicating that the urban nighttime chemistry is more active than the  
31 background marine regions. N<sub>2</sub>O<sub>5</sub> uptake coefficient and ClNO<sub>2</sub> production yield were estimated by  
32 measured parameters based on the field measurement, and the performance of the previously derived  
33 parameterizations were-was assessed. The nighttime ClNO<sub>2</sub> correlated with particulate chloride and  
34 the mass concentration of fine particles (most likely due to aerosol surface area), but not with nitrate  
35 radical formation rate, suggested that the ClNO<sub>2</sub> formation was limited by the N<sub>2</sub>O<sub>5</sub> uptake rather  
36 than N<sub>2</sub>O<sub>5</sub>-source at this site. By examining the relationship of-between particulate chloride and other  
37 species, we implied that anthropogenic emissions (e.g., biomass burning) rather than sea salt  
38 particles dominate the origin of particulate chloride, despite-although the site is being only about 100  
39 km away from the ocean. A box model with detailed chloride chemistry-chlorine chemistry is used to  
40 investigate the impacts of ClNO<sub>2</sub> chemistry on atmospheric oxidation. Model simulations showed the  
41 chloride radical-chlorine radical liberated by ClNO<sub>2</sub> photolysis during the next day had a small-slight  
42 increase in concentrations of OH, HO<sub>2</sub> and RO<sub>2</sub> radicals, as well as minor contributions to RO<sub>2</sub>  
43 radical and O<sub>3</sub> formation (<5%, on daytime average) in all the three types of air masses. Relative  
44 higher contributions were observed in Type A and B. The overall low contributions of ClNO<sub>2</sub> to  
45 atmospheric oxidation are consistent with those reported recently from wintertime observations in  
46 China (included-including Shanghai, Beijing, Wangdu and Mt. Tai). This may be attributed to: (1)  
47 Relative low particle mass concentration limited ClNO<sub>2</sub> formation; (2) Other reactions channels, like  
48 nitrous acid (HONO), oxygenated volatile organic compounds (OVOCs, including formaldehyde),  
49 and ozone photolysis, had larger-more significant radical formation rate during the ozone pollution  
50 episodes and weakened the ClNO<sub>2</sub> contribution indirectly. The results provided scientific insights  
51 into the role of nighttime chemistry in photochemical pollution under various scenarios in coastal  
52 areas.

53

54 

## 1. Introduction

55 Chloride radicalChlorine radical is an important oxidant in the tropospheric besides OH radicals,  
56 NO<sub>3</sub> radicals and ozone (Saiz-Lopez and von Glasow, 2012; Simpson et al., 2015; Wang et al.,  
57 2019b), which alters the fate of many atmospheric compositions, including oxidants, reactive  
58 nitrogen compounds, volatile organic compounds (VOCs), and other halogens. Cl radical is much  
59 more reactive than OH ~~with respect to~~concerning certain VOCs (e.g., alkanes) by a few orders of  
60 magnitude for reaction rate constant (Atkinson and Arey, 2003; Atkinson et al., 2006), therefore, it  
61 contributes to atmospheric oxidation capacity considerably in the troposphere despite low  
62 concentrations. For example, the global model showed ~~about~~ 20 % of ethane, 14 % of propane  
63 oxidation are attributed to ~~the~~ chloride chemistrychlorine chemistry at the global scale (Wang et al.,  
64 2019c). Modeling simulations also demonstrated that chloride chemistrychlorine chemistry enhanced  
65 oxidative degradation of VOCs by >20% at some locations (Sarwar et al., 2014).

66 Photolysis of ClNO<sub>2</sub> (R1) is a major source of the tropospheric ~~chloride radical~~chlorine radical  
67 (Thornton et al., 2010b; Simpson et al., 2015), other ~~chloride radical~~chlorine radical sources include  
68 the reaction of HCl with OH (Riedel et al., 2012; Eger et al., 2019), photolysis of Cl<sub>2</sub> and other  
69 halogen compounds like ICl and BrCl (Peng et al., 2021). Tropospheric ClNO<sub>2</sub> is not only ~~an~~  
70 importantcritical chlorine activation precursor but also a nocturnal ~~reservoir~~reservoir of reactive  
71 nitrogen, which is mainly formed ~~in~~by N<sub>2</sub>O<sub>5</sub> heterogeneous reaction ~~of~~on chlorine-containing  
72 particles with a ~~branch~~branching ratio at nighttime (R2).

75 where  $\varphi$  represents the yield of ClNO<sub>2</sub>. This mechanism was firstly proposed by Finlaysonpitts et al.  
76 (1989) through detecting the products of N<sub>2</sub>O<sub>5</sub> uptake on NaCl particles. Given this reaction, the  
77 formation of ClNO<sub>2</sub> can be influenced by the N<sub>2</sub>O<sub>5</sub> uptake (such as N<sub>2</sub>O<sub>5</sub> uptake probabilities and  
78 aerosol surface area) as well as the production yield of ClNO<sub>2</sub>.

79 N<sub>2</sub>O<sub>5</sub> uptake coefficient,  $\gamma(\text{N}_2\text{O}_5)$ , have been reported highly varied under tropospheric conditions  
80 (Brown and Stutz, 2012). Both the field and laboratory studies revealed that this process can be  
81 affected by ambient temperature, relative humidity (Mozurkewich and Calvert, 1988; Mentel et al.,  
82 1999; Hallquist et al., 2003), chemical compositions (such as the content of nitrate, liquid water,  
83 chloride, and organics) (Mentel et al., 1999; Brown et al., 2006; Bertram and Thornton, 2009; Gaston

设置了格式: 下标

设置了格式: 下标

84 et al., 2014; McDuffie et al., 2018b; Tang et al., 2014; Anttila et al., 2006), as well as particle  
85 morphology (Mielke et al., 2013; Zong et al., 2021). Until now, the key factors that controlling N<sub>2</sub>O<sub>5</sub>  
86 uptake coefficient in the different environments are still not well understood. ClNO<sub>2</sub> yield is also  
87 highly varied subject to the liquid water and chloride content in the aerosol (Behnke et al., 1997;  
88 Roberts et al., 2009; Bertram and Thornton, 2009). Several studies demonstrated that the ClNO<sub>2</sub>  
89 yield is also affected by other factors like aerosol sulfate (Staudt et al., 2019) and organics (Ryder et  
90 al., 2015; Tham et al., 2018; McDuffie et al., 2018a). However, the comprehensive quantitative  
91 relationship of these factors in controlling the yield still has large uncertainties. These gaps in  
92 parameterization of N<sub>2</sub>O<sub>5</sub> uptake coefficients and ClNO<sub>2</sub> yield result in challenging to accurately  
93 predict ClNO<sub>2</sub> and particulate nitrate production. These gaps in understanding the critical controlling  
94 factors for N<sub>2</sub>O<sub>5</sub> uptake coefficient as well as ClNO<sub>2</sub> yield lead to the prediction of ClNO<sub>2</sub> and  
95 particulate nitrate production very challenge.

96 Osthoff et al. (2008) and Thornton et al. (2010a) directly observed elevated ClNO<sub>2</sub> in coastal and  
97 inland U.S. by chemical ionization mass spectrometer (CIMS), respectively. They shed light on the  
98 significance of ClNO<sub>2</sub> photolysis in launching the radical chemistry during the morning time, and  
99 also affecting halogen chemistry and reactive nitrogen cycling. Large amounts of chloride  
100 radicalchlorine radicals are liberated through the photolysis of nocturnal accumulated ClNO<sub>2</sub> (R1),  
101 which oxidizes VOCs and produces peroxy radicals (RO<sub>2</sub>) to initiate the daytime radical cycling in  
102 the morning, when other radical source, like ozonolysis and photolysis of O<sub>3</sub>, HONO and HCHO, are  
103 still weak (Osthoff et al., 2008). The impacts of ClNO<sub>2</sub> chemistry on primary source of radicals and  
104 ozone formation is a critical topic, the answer of which is very helpful to narrow the gap of the  
105 missing primary source of ROx and improve our knowledge of the correct ozone pollution  
106 mechanism (Tan et al., 2017; Tham et al., 2016). Model simulation highlighted ClNO<sub>2</sub> chemistry  
107 could increase mean daily maximum 8 h ozone by up to 7.0 ppbv in some areas in the Northern  
108 Hemisphere (Sarwar et al., 2014). The large contribution was also confirmed in the southern  
109 California region by a box model study (Riedel et al., 2014). In addition, global model simulation  
110 showed ClNO<sub>2</sub> chemistry increases wintertime ozone by up to 8 ppb over polluted continents (Wang  
111 et al., 2019c). Particularly, previously modelling results also highlight the importance of ClNO<sub>2</sub>  
112 chemistry in enhancing O<sub>3</sub> production in China (Li et al., 2016; Yang et al., 2022b).

113 Several field studies reported the measurement of ClNO<sub>2</sub> in varied environments in the past  
114 decade (Riedel et al., 2012; Young et al., 2012; Mielke et al., 2013; Riedel et al., 2013; Bannan et al.,  
115 2015; Faxon et al., 2015; Mielke et al., 2015; Phillips et al., 2016; Bannan et al., 2017; Wang et al.,  
116 2017c; Wang et al., 2017d; Le Breton et al., 2018; McDuffie et al., 2018a; Yun et al., 2018a; Zhou et  
117 al., 2018; Bannan et al., 2019; Eger et al., 2019; Haskins et al., 2019; Jeong et al., 2019; Xia et al.,

118 2020; Xia et al., 2021; Tham et al., 2016; Tham et al., 2014; Wang et al., 2016; Phillips et al., 2012;  
119 Lou et al., 2022; Sommariva et al., 2018), in which the maximum ClNO<sub>2</sub> up to sub-ppbv to several  
120 ppbv were reported, indicating its ubiquitous~~ubiquity~~ presence worldwide and a broad atmospheric  
121 impacts over various regions. During the CalNex-LA campaign 2010, ClNO<sub>2</sub> was measured at  
122 ground site, the Research Vessel and aircraft platform, which depicted a full picture of the abundance  
123 of ClNO<sub>2</sub> and confirmed its large impacts on atmospheric chemsity in both urban and coastal  
124 regions in California (Riedel et al., 2012; Young et al., 2012; Mielke et al., 2013). Recently, Wang et  
125 al. (2016) used a box model simulated the chemical evolution of the plume after leaving the  
126 observation site in Hongkong and showed ClNO<sub>2</sub> chemistry had a following-day enhancement of  
127 ozone peak and daytime ozone production rate by 5–16% and 11–41%, along with a large increasing  
128 of OH, HO<sub>2</sub> and RO<sub>2</sub> concentration especially in the morning. While Xia et al. (2021) and Lou et al.  
129 (2022) reported winter measurments of ClNO<sub>2</sub> in north and east China, respectively, ~~both~~ they both  
130 showed moderate ClNO<sub>2</sub> level and a relative small contributions of ClNO<sub>2</sub> chemistry to radical  
131 source and ozone enhancement on campaign average. These results is quite different with that  
132 happened during the summertime in China (Tham et al., 2016; Wang et al., 2016; Tan et al., 2017),  
133 and highlight the large variation of ClNO<sub>2</sub> chemistry influenced by temporal spatial distribution.

134 Despite its likely importance to the regional atmospheric oxidation and air quality, investigations  
135 of ClNO<sub>2</sub> chemistry in China remain relatively sparse. There are several field measurements of  
136 ClNO<sub>2</sub> conducted in the China in recent years, while considering the large diversities of air mass in  
137 inland and coastal regions in China, more field and model works are need to gain more insights to  
138 the ClNO<sub>2</sub> chemistry in various atmospheric environments and assess its atmospheric impacts. Until  
139 now, only several field measurement of ClNO<sub>2</sub> were reported in Pearl River Delta (PRD) region  
140 (Tham et al., 2014; Wang et al., 2016; Yun et al., 2018a), and only Wang et al. (2016) reported a  
141 comprehensive analysis of the impact of ClNO<sub>2</sub> chemistry on radical and ozone formation in 2013 as  
142 mentioned before. To understanding the increasing O<sub>3</sub> problem in recent years (Wang et al., 2019a)  
143 and examining the role of ClNO<sub>2</sub> chemistry in O<sub>3</sub> formation in PRD, we measured ClNO<sub>2</sub>, N<sub>2</sub>O<sub>5</sub>, and  
144 other related parameters at a regional site in PRD during a severe photochemical pollution season in  
145 2019. The abundance, formation, and variation during different air masses patterns are well  
146 characterized. The factors impact its formation are diagnosed. Finally, the contribution of ~~chloride~~  
147 radical~~chlorine~~ radicals liberated by ClNO<sub>2</sub> photolysis on the daytime radical chemistry, as well as  
148 ozone formation are comprehensively assessed by a box model coupled with detailed ~~chloride~~  
149 chemistry~~chlorine~~ chemistry.

150 **2. Method**

151 **2.1 Measurement site**

152 This campaign was conducted at the Guangdong Atmospheric Supersite of China, which is located  
153 on the top of a mountain (~ 60 m high, a.s.l.) in Heshan (22.728°N, 112.929°E), Jiangmen city,  
154 Guangdong Province (Yang et al., 2022a). This site was in the western Peral River Delta where no  
155 major industry in the surroundings, but with some farmland and a few residents live at the hill foot.  
156 The traffic is far away from this site and believed to have little influence on the sampling~~seldom~~  
157 ~~disturbs the sampling~~. The anthropogenic activity is much lower than the urban regions like  
158 Guangzhou City, but the air quality is often influenced by neighbor cities, especially the outflow of  
159 air masses from the regions on the north and northeast. Therefore, the air masses sampled at this site  
160 are sometimes representative of the urban pollution from the center PRD. There were many  
161 atmospheric intensive studies once conducted in the site to study the air pollutions in PRD (Tan et al.,  
162 2019; Yun et al., 2018b). In this study, the instruments were located on the top floor of the  
163 measurement building with inlets approximately 15 m above the ground. The data presented in the  
164 study were collected from 27<sup>th</sup> September to 17<sup>th</sup> November 2019, during which photochemical  
165 pollution occurred frequently (Yang et al., 2022a). Time is given as CNST (Chinese National  
166 Standard Time = UTC+8 h). During the campaign, sunrise was approximately at 06:00 and sunset  
167 was approximately at 18:00 CNST.

设置了格式: 字体: (默认) Times New Roman

168 **2.2 Instrument setup**

169 A comprehensive suite of instrumentation was overviewed and listed in Table 1. An iodide-adduct  
170 Time-of-Flight Chemical Ionization Mass Spectrometer (ToF-CIMS) with the Filter Inlet for Gas and  
171 AEROSols (FIGAERO) was applied to measure ClNO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> along with other oxygenated  
172 organic species (Ye et al., 2021; Wang et al., 2020b). In brief, the gas phase species were measured  
173 via a 2-m-long, 6-mm-outer-diameter PFA inlet while the particles were simultaneously collected on  
174 a Teflon filter via a separate 2-m-long, 10-mm-outer-diameter copper tubing inlet; both had flow  
175 rates of 2 L min<sup>-1</sup> with a drainage flow of 20 L min<sup>-1</sup>. The gas phase was measured for 25 minutes at  
176 1 Hz, and the FIGAERO instrument was then switched to place the filter in front of the ion molecule  
177 region; it was then heated incrementally to 200 °C to desorb all the mass from the filter to be  
178 measured in the gas phase, which resulted in high-resolution thermograms. ClNO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> are  
179 measured as the iodide adduct ions at m/z 207.867 (IClNO<sub>2</sub><sup>-</sup>) and m/z 234.886 (IN<sub>2</sub>O<sub>5</sub><sup>-</sup>) in the ToF-  
180 CIMS, respectively. The measurement background and sensitivities for detecting ClNO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub>  
181 with the dependence of water content were quantified ~~and described in details~~ (see Appendix). The  
182 limit of detection (LOD) for ClNO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> were 4.3 and 6.0 pptv in 1-minute time-resolution,  
183 respectively, with an uncertainty of ~30%.

184 Sub-micron aerosol composition (PM<sub>1</sub>) were measured by a High-Resolution Time of Flight  
 185 Aerosol Mass Spectrometer (HR-ToF-AMS) (DeCarlo et al., 2006). The soluble ions of sodium and  
 186 potassium was measured by a commercial instrument (GAC-IC) equipped with an aerosol collector  
 187 and detected by ion chromatography (Dong et al., 2012). The particle number size distribution  
 188 (PNSD) was measured by a scanning mobility particle sizer (SMPS, TSI 3938). The aerosol surfaces  
 189 area was calculated based on the size distribution measurement and corrected to wet particle-state by  
 190 a hygroscopicity growth factor, with a total uncertainty of determining wet aerosol surface areas by  
 191 ~30% (Liu et al., 2013). VOCs were measured by Proton Transfer Reaction Time-of-Flight Mass  
 192 Spectrometry (PTR-MS)(Wu et al., 2020; He et al., 2022) and an automated gas chromatograph  
 193 equipped with mass spectrometry or flame ionization detectors (GC-MS). A commercial instrument  
 194 (Thermo Electron model 42i) was used to monitor NO<sub>x</sub>. O<sub>3</sub> was measured by a commercial  
 195 instrument using ultraviolet (UV) absorption (Thermo Electron 49i). PM<sub>2.5</sub> was measured by a  
 196 Tapered Element Oscillating Microbalance (TEOM, 1400A analyzer). SO<sub>2</sub> and CO were measured  
 197 by commercial instruments (Thermo Electron 43i and 48i). In addition, the meteorological  
 198 parameters were available during the measurement. Photolysis frequencies were determined by a  
 199 spectroradiometer (Bohn et al., 2008). The aerosol liquid water content (ALWC) is calculated from  
 200 the ISORROPIA-II thermodynamic equilibrium model (Clegg et al., 1998). We used the reverse  
 201 mode in ISORROPIA-II with the input of water-soluble ions along with ambient temperature (*T*) and  
 202 relative humidity (RH). Given the high RH in this campaign, we ran the model by assuming aerosol  
 203 phase were metastable.

204 **Table 1.** Summary of the information about observed gas and particle parameters during the  
 205 campaign.

Species	Limit of detection	Methods	Accuracy
N <sub>2</sub> O <sub>5</sub>	6.0 pptv (3 $\sigma$ , 1 min)	FIGAERO-ToF-CIMS	$\pm$ 30%
ClNO <sub>2</sub>	4.3 pptv (3 $\sigma$ , 1 min)	FIGAERO-ToF-CIMS	$\pm$ 30%
NO	60 pptv (2 $\sigma$ , 1 min)	Chemiluminescence	$\pm$ 20%
NO <sub>2</sub>	0.3 ppbv (2 $\sigma$ , 1 min)	Mo convert	$\pm$ 20%
O <sub>3</sub>	0.5 ppbv (2 $\sigma$ , 1 min)	UV photometry	$\pm$ 5%
VOCs	0.1 ppbv (5 min)	PTR-ToF-MS	$\pm$ 30%
VOCs	20-300 pptv (1 h)	GC-FID/MS	$\pm$ 20%
PM <sub>2.5</sub>	0.1 $\mu$ g m <sup>-3</sup> (1 min)	TEOM	$\pm$ 5%
CO	4 ppbv (5 min)	IR photometry	$\pm$ 5%
SO <sub>2</sub>	0.1 ppbv (1 min)	Pulsed UV fluorescence	$\pm$ 10%
HCHO	25 pptv (2 min)	Hantzsch fluorimetry	$\pm$ 5%
PNSD	14 nm -700 nm (4 min)	SMPS	$\pm$ 20%
Aerosol composition	<0.16 $\mu$ g m <sup>-3</sup> (30 min)	GAC-IC	$\pm$ 30%
PM <sub>1</sub> components	0.15 $\mu$ g m <sup>-3</sup> (4 min)	HR-ToF-AMS	$\pm$ 30%
Photolysis frequencies	Varies with species (20 s)	Spectroradiometer	$\pm$ 10%

206

## 207 2.3 Box model setup

208 A zero-dimensional chemical box model constrained by the field campaign data was applied to  
209 simulate the ClNO<sub>2</sub> chemistry. The box model was based on the Regional Atmospheric Chemical  
210 Mechanism version 2 (RACM2) described in Goliff et al. (2013), and [chloride-chlorine-related](#)  
211 chemical mechanism ~~were~~[was](#) added (Wang et al., 2017b; Tan et al., 2017). Briefly, [chloride](#)  
212 [chemistry](#)[chlorine chemistry](#) was adapted to RACM2 from the modifications to Master Chemical  
213 Mechanism (Xue et al., 2015), and the oxidation products from reactions between lumped VOC  
214 species and [chloride radical](#)[chlorine radicals](#) were adapted from those of OH oxidation from RACM2.  
215  $j(\text{ClNO}_2)$  was calculated according to the NASA-JPL recommendation based on the work by Ghosh  
216 et al. (2012). The impact of O<sub>3</sub> by ClNO<sub>2</sub> chemistry was assessed by differing the results of two  
217 scenarios [with and without the constrains of the observed ClNO<sub>2</sub>](#)[with or without the constraints of](#)  
218 [the observed ClNO<sub>2</sub>](#) in the model simulation. For the reaction rate constant of the lumped species  
219 with Cl, the fastest value from different species was used to represent the upper limit of the impact of  
220 [chloride chemistry](#)[chlorine chemistry](#). It should be note that the setting will lead to overestimation on  
221 [the contributions from ClNO<sub>2</sub> chemistry](#). The model was constrained by the observed ClNO<sub>2</sub>, NO<sub>x</sub>,  
222 O<sub>3</sub>, CO, VOCs (assignment to RACM2), photolysis frequencies, ambient ~~temperature~~[temperature](#),  
223 and pressure. The model runs were from 29 September to 17 November, 2019 with most of the  
224 measurement data taken accounted for, and with a two-days spin-up. The [constant](#) lifetime [of the](#)  
225 [input trace gases](#) corresponds to a deposition velocity of 1.2 cm s<sup>-1</sup> with an assumed boundary layer  
226 height of 1000 m [was used for the input trace gases](#), and the model-generated species [was](#)[were](#) set to  
227 24 hours lifetime due to the loss caused by the dry deposition (Lu et al., 2012). The input data were  
228 averaged and interpolated to 1 hour of resolution.

## 229 3. Results and discussions

### 230 3.1 Overview of measurement

231 Figure 1 shows time series of ClNO<sub>2</sub> and relevant trace gases, ~~particulate~~[particles](#), and meteorological  
232 parameters during the measurements. In this campaign, the meteorological condition featured high  
233 temperature ( $24.7 \pm 3.8^\circ\text{C}$ ) and high humidity ( $62.1\% \pm 15.6\%$ ), low wind speed ( $1.5 \pm 0.8 \text{ m s}^{-1}$ ),  
234 and the dominant air flow were from north and northwest. Compared to those with previously

235 measurements at the same site in January 2017 (Yun et al., 2018b), the temperature was higher and  
 236 relative humidity was lower during the measurements. The average and maximum concentration of  
 237 particulate matter (PM<sub>2.5</sub>) was  $47.6 \pm 19.3 \mu\text{g m}^{-3}$  and  $138 \mu\text{g m}^{-3}$ , respectively, which is significantly  
 238 lower than that observed in January 2017, with a maximum up to  $400 \mu\text{g m}^{-3}$ . The dominant air  
 239 pollutant was O<sub>3</sub> with hourly campaign maximum and the average mean daily maximum 8-hour O<sub>3</sub>  
 240 (MDA8 O<sub>3</sub>) of 152.8 ppbv and  $75.2 \pm 20.9$  ppbv, respectively. There were 27 days out of 53 days  
 241 with the hourly maximum of O<sub>3</sub> exceeded the Chinese national air quality standard ( $200 \mu\text{g m}^{-3}$ ,  
 242 equivalent to 93 ppbv), suggesting severe ozone pollution during the measurement period in PRD  
 243 region. NO<sub>2</sub> concentration was also elevated with  $21.0 \pm 10.4$  ppbv on campaign average. The  
 244 concurrent high O<sub>3</sub> and NO<sub>2</sub> made large nitrate radical production rate occurred with a daily average  
 245 of  $2.5 \pm 1.8 \pm 2.1 \text{ ppbv h}^{-1}$  (median,  $1.8 \text{ ppbv h}^{-1}$ ). The campaign maximum NO<sub>3</sub> production rate was  
 246 observed up to  $18.6 \text{ ppbv h}^{-1}$  in the afternoon at 11<sup>th</sup> November, 2019. At night, the nitrate radical  
 247 production rate was  $1.8 \pm 1.5 \text{ ppbv h}^{-1}$  on campaign average (median,  $1.4 \text{ ppbv h}^{-1}$ ). However, high  
 248 NO<sub>3</sub> production rate did not mean high concentrations of NO<sub>3</sub>, N<sub>2</sub>O<sub>5</sub> and ClNO<sub>2</sub> in the atmosphere,  
 249 as the concentration affected by both their sources and sinks.

250  
 251 **Figure 1.** Time series of N<sub>2</sub>O<sub>5</sub>, ClNO<sub>2</sub> and relevant parameters. The grey dotted line in the O<sub>3</sub> panel  
 252 denotes Chinese national air quality standard for hourly maximum O<sub>3</sub> ( $200 \mu\text{g m}^{-3}$ , equivalent to 93  
 253 ppbv). NO<sub>3</sub> radical is calculated based on a thermal equilibrium with measured NO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub>.

254  $\text{N}_2\text{O}_5$  existed at a moderate concentration at most nights, with the daily nocturnal peaks range from  
255 <100 pptv to 1180 pptv and nocturnal average of  $64 \pm 145$  pptv. During the nights from 27<sup>th</sup> – 30<sup>th</sup>  
256 September, 2019, the  $\text{N}_2\text{O}_5$  concentration was significantly higher than other nights. The  $\text{NO}_3$   
257 lifetime, calculated by steady state method (Brown et al., 2003), was much longer in the four nights  
258 than other nights, implied relative weak sink of  $\text{NO}_3\text{-N}_2\text{O}_5$  for the first four nights. The lifetime of  
259  $\text{NO}_3$  was < 1 minute in general (except the first four nights), indicating active  $\text{NO}_3$  chemistry at this  
260 site. The  $\text{NO}_3$  concentration was calculated assuming the thermal equilibrium of  $\text{NO}_2\text{-NO}_3\text{-N}_2\text{O}_5$ ,  
261 with a possible lower bias caused by the equilibrium coefficient for reversible reactions of  $\text{NO}_3$  and  
262  $\text{N}_2\text{O}_5$  ( $K_{eq}$ ) (Chen et al., 2022). Figure 1 shows the variation of calculated  $\text{NO}_3$  coincided with  $\text{N}_2\text{O}_5$ .  
263 Elevated  $\text{NO}_3$  occurred at the first four nights with a maximum of 90 pptv (1 h time resolution),  
264 which is comparable with the reported  $\text{NO}_3$  level at other sites in Pearl River Delta (Wang and Lu,  
265 2019; Brown et al., 2016).  $\text{ClNO}_2$  showed a clear diurnal variation with high level during the night.  
266 The nocturnal average and hourly maximum were  $198 \pm 232$  pptv and 1497 pptv, respectively. The  
267 abundance of  $\text{ClNO}_2$  and  $\text{N}_2\text{O}_5$  are lower than those observed at the same site in 2017, with high  
268  $\text{N}_2\text{O}_5$  and the highest value ever observed  $\text{ClNO}_2$  of 3358 pptv and 8324 pptv (1-minute time  
269 resolution), respectively (Yun et al., 2018b). Which<sup>▲</sup>The difference of  $\text{ClNO}_2$  level between the two  
270 campaigns conducted in 2017 and 2019 may be caused by the difference of aerosol loading between  
271 2017 and 2019. High particulate chloride ion was observed in the site with  $0.74 \pm 1.33 \mu\text{g m}^{-3}$  on  
272 nocturnal average, which was higher at night with a peak in the second half of night and decrease at  
273 daytime.

### 274 3. 2 Characterization of pollutants in different air masses.

275 We noticed the air mass is highly varied during the measurements. For example, during the period of  
276 10/02 - 10/05, the observed ozone and  $\text{ClNO}_2$  were much lower than other days; while during the  
277 period of 11/11 - 11/13, the air masses were much polluted with high  $\text{O}_3$ ,  $\text{PM}_{2.5}$  and  $\text{ClNO}_2$ . We  
278 therefore plotted the backward trajectories of 24 h history of air masses arriving at the measurement  
279 site at 500 m AMSL height at 00:00, 06:00, 12:00, 18:00 day by day. The measurement period was  
280 separated into three patterns meteorologically according to the analysis of backward trajectories.  
281 Table 2 listed the detailed information about the air mass classification. The air masses from  
282 northeast (and north) was the dominant with a total of 37 days, which was characterized with the  
283 outflow of the center city clusters of PRD and those from inland through long distance transport. We  
284 checked the pollutants of the air masses from PRD and the north out of PRD (e.g., Hunan or Jiangxi  
285 Province), while no significant difference was found. Therefore, we merged the two inland air  
286 masses as Type A. The second type was from the coastal or offshore from east and southeast (Type

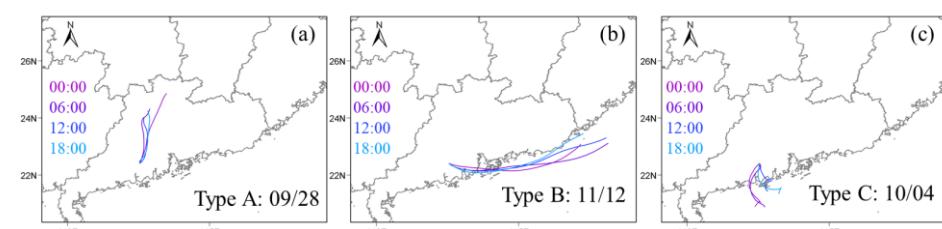

设置了格式: 非突出显示  
设置了格式: 下标, 非突出显示  
设置了格式: 非突出显示  
设置了格式: 非突出显示

287 B), which features the outflow of coastal cities like Shenzhen and Hong Kong, which occurred on 12  
 288 days in total. The third type was the clean air masses from the South China Sea (4 days, Type C).  
 289 Figure 2 shows three cases of each air masses mentioned above.

290 **Table 2.** The detailed information of three air mass types.

Air mass type	Periods	Days
Type A: inland air from northeast	09/26-10/01; 10/08; 10/11-10/20; 10/24- 11/10; 11/14-15	37 (69.8%)
Type B: coast air from east	10/06-07; 10/09-10; 10/21-23; 11/11-13; 11/16-17	12 (22.6%)
Type C: marine air from south	10/02-05	4 (7.5%)

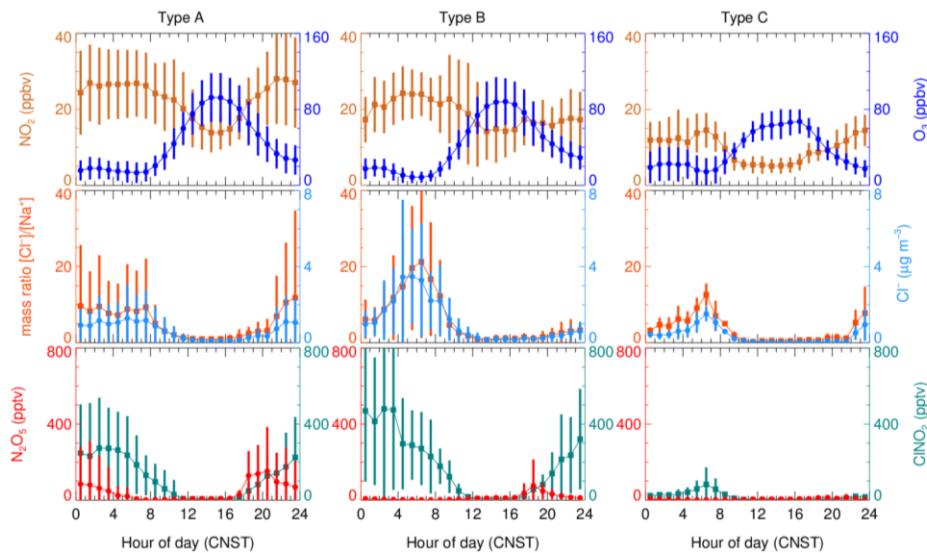

291 The mean diurnal profiles of measured  $\text{NO}_2$ ,  $\text{O}_3$ ,  $\text{N}_2\text{O}_5$ ,  $\text{CINO}_2$ , the particle chloride content and  
 292 the ratio of chloride to sodium in the three types of air masses are shown in Figure 3, with a detailed  
 293 summary of related parameters in nocturnal medians listed in Table 3. High levels of  $\text{NO}_2$  and  $\text{O}_3$   
 294 were observed in Type A and B air masses, with small difference of  $\text{NO}_2$  diurnal variation during the  
 295 second half of night. In comparison, the two pollutants in Type C were much lower. If we focus on  
 296 the abundance at night, we found a large difference in  $\text{NO}_2$  level with a sequence Type A > Type B >  
 297 Type C, which results in the same sequence of  $\text{NO}_3^-$  productions in different air masses. The  
 298 nocturnal  $\text{NO}_2$  seems to be a good indicator of the level of pollution, that nocturnal  $\text{CO}$ ,  $\text{PM}_{2.5}$  and  
 299  $\text{SO}_2$  also followed this order with highest concentration in Type A. These results indicate that the  
 300 most polluted air mass came from the inland urban regions of PRD.

301  
 302 **Figure 2.** Three typical cases with air mass from different regions at 29<sup>th</sup> Sept., 12<sup>th</sup> Nov. and 4<sup>th</sup> Oct.,  
 303 respectively. Backward trajectory of 24 h history of air masses arriving at the measurement site with  
 304 500 m height at 00:00, 06:00, 12:00, 18:00.

305 Given the particulate chloride a precursor of  $\text{CINO}_2$ , we examined its diurnal variations in the  
 306 three air mass types. The highest level of  $\text{Cl}^-$  was found in Type B, and then followed by Type A and  
 307 Type C (also at night). Although the diurnal profile of  $\text{Cl}^-$  in the three types is similar, the increasing

308 rate of  $\text{Cl}^-$  during the second half of night in Type A is much slower than those in coastal and offshore  
 309 air masses. This imply a difference source of chloride, which will be further discussed in the Section  
 310 3.4.  $\text{N}_2\text{O}_5$  was observed with moderate concentration in the Type A air mass throughout the night,  
 311 with a nocturnal peak of 152.4 pptv between 20:00-21:00, while little  $\text{N}_2\text{O}_5$  only occurred in the first  
 312 half of night in Type B and C with a peak of 75.9 pptv and 13.6 pptv, respectively. The concentration  
 313 difference may be attribute to two aspects. Firstly, the difference of  $\text{P}(\text{NO}_3)$  results in more  $\text{N}_2\text{O}_5$   
 314 produced in Type A. Secondly, compared with the air mass from coastal or offshore regions, the  
 315 nocturnal temperature and RH condition from Type A is much lower, and the loss of  $\text{N}_2\text{O}_5$  may be  
 316 faster in Type B and C than that in Type A. The nocturnal median RH in Type A reached up to 67%,  
 317 while 78% and 79% in Type B and Type C, suggesting a favorable condition for heterogeneous  
 318 hydrolysis of  $\text{N}_2\text{O}_5$  for all the three air mass types. The elevated  $\text{ClNO}_2$  was observed in Type A and  
 319 B with a nocturnal peak of 273.6 pptv and 479.8 pptv, respectively. Significantly less  $\text{ClNO}_2$  was  
 320 observed in Type C air mass with a peak of 82.6 pptv. The reason of the different levels of  $\text{ClNO}_2$   
 321 observed in the three air masses types are discussed in Section. 3.4.

322  
 323 **Figure 3.** Mean diurnal profiles of  $\text{N}_2\text{O}_5$ ,  $\text{ClNO}_2$  and relevant parameters in the three types of air  
 324 masses.

325 **Table 3.** Statistics results (median  $\pm$  standard deviation) of the related parameters in the three types  
 326 of air masses (from 18:00 to 06:00 CNST).

Air mass	Type-A	Type-B	Type-C
RH (%)	67.0 $\pm$ 11.9	78.0 $\pm$ 10.9	79.0 $\pm$ 9.1

### 3.3 N<sub>2</sub>O<sub>5</sub> uptake coefficient and ClNO<sub>2</sub> yield

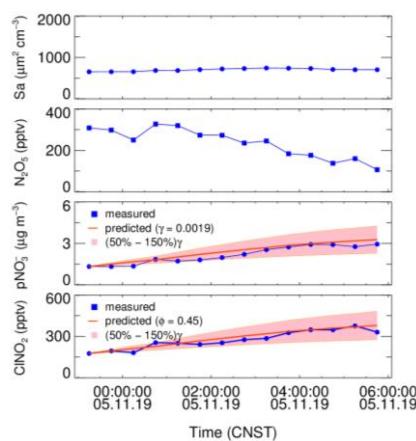

In line with previous studies, we estimate N<sub>2</sub>O<sub>5</sub> uptake coefficient and ClNO<sub>2</sub> yield using the measurements of N<sub>2</sub>O<sub>5</sub>, ClNO<sub>2</sub> and particulate nitrate (Phillips et al., 2016; Wang et al., 2018; Tham et al., 2018). By assuming both the nocturnal enhancement of nitrate and ClNO<sub>2</sub> are mainly attributed to N<sub>2</sub>O<sub>5</sub> uptake processes, ClNO<sub>2</sub> yield can be solely derived by the regression analysis of ClNO<sub>2</sub> versus particulate nitrate (Wagner et al., 2012; Riedel et al., 2013). The  $\varphi$ ClNO<sub>2</sub> can then be obtained by the fitted regression slope (S, Eq. 1) and named as regression method.

$$\varphi = 2S/(S+1) \quad (\text{Eq. 1})$$

Combining with the data of N<sub>2</sub>O<sub>5</sub> and aerosol surface area, the increase in ClNO<sub>2</sub> and nitrate can be simulated simultaneously by setting the input of N<sub>2</sub>O<sub>5</sub> uptake coefficient and ClNO<sub>2</sub> yield (named as simulation method). The optimal N<sub>2</sub>O<sub>5</sub> uptake coefficient and ClNO<sub>2</sub> yield are obtained simultaneously by adjusting the two parameters until the simulation reproduces the observed increase ClNO<sub>2</sub> and nitrate (Phillips et al., 2016; Xia et al., 2020; Tham et al., 2018). This analysis assumes only N<sub>2</sub>O<sub>5</sub> uptake process dominates the increase of ClNO<sub>2</sub> and nitrate, and other physicochemical processes like vertical transportation, depositions are less important. This method requests the air mass in the analysis duration time is relative stable and less affected by emission and transportation. In addition, it is not valid in the case with negative changes of ClNO<sub>2</sub> and nitrate. The following selection criteria is set to pick out the suitable plumes to meet the assumptions. Firstly, the consistent increase trends of ClNO<sub>2</sub> and the NO<sub>3</sub><sup>-</sup> and clear correlation between them during the analysis duration should be observed with a regression coefficient threshold of 0.5, which indicates the two products have the same source. Secondary, an equivalent or faster increase of ammonium accompanied with nitrate, to ensure insignificant degas of HNO<sub>3</sub> to the atmosphere. The observational data were averaged to 30 min for the following analysis, the time-period of each derivation ranges from 2.5 to 10 hours. Figure 4 depicts an example of the derivation on 5<sup>th</sup>

351 November, 2019, the stable Sa indicates stable air mass during the analysis period. And the  
 352 prediction is well reproduced the observed increase in  $\text{ClNO}_2$  and  $\text{NO}_3^-$ .

353 During this campaign, we carefully identified 20 plumes with clear correlations between  $\text{ClNO}_2$   
 354 and particulate nitrate by the slope method ( $R^2 \geq 0.5$ ). As shown in Table 4, the derived  $\text{ClNO}_2$  yield  
 355 varied from 0.13 to 1.00 with a median of  $0.45 \pm 0.22$  (mean value of 0.44). In the 20 plumes, we  
 356 derived  $\text{N}_2\text{O}_5$  uptake coefficient and  $\text{ClNO}_2$  for 12 cases in total. The results in other 8 night were not  
 357 valid due to the lack of Sa data (four nights) or producing unreasonably high results due to the  
 358 observed low  $\text{N}_2\text{O}_5$  concentration near the detection limit biased the simulations. We show good  
 359 consistent of derived  $\text{ClNO}_2$  yields by the two different methods. The estimated  $\text{N}_2\text{O}_5$  uptake  
 360 coefficient showed a large variation and ranged from 0.0019 to 0.077 with a median of  $0.0195 \pm$   
 361 0.0288 (mean value of 0.0317). The estimated  $\gamma_{\text{N}_2\text{O}_5}$  is within the range determined by previous  
 362 field studies (Tham et al., 2018). Specifically in China, the average level of  $\gamma_{\text{N}_2\text{O}_5}$  is comparable  
 363 with those reported in urban Beijing (Wang et al., 2017a; Wang et al., 2018), Wangdu (Tham et al.,  
 364 2018), and Jinan (Wang et al., 2017c) during the summertime, but systematically higher than those  
 365 determined in China in wintertime (Xia et al., 2021; Wang et al., 2020a; Brown et al., 2016), except  
 366 the case reported on the urban canopy of Beijing (Chen et al., 2020). McDuffie et al. (2018a)  
 367 summarized the reported  $\varphi_{\text{ClNO}_2}$  based on the observations, and we showed that the estimated  
 368 average  $\varphi_{\text{ClNO}_2}$  in this study is in the middle to upper end of the values reported globally (Xia et al.,  
 369 2021; McDuffie et al., 2018a). Due to the limited data points, we cannot distinguish the difference of  
 370  $\gamma_{\text{N}_2\text{O}_5}$  between the three air mass patterns. The  $\text{ClNO}_2$  yields in Type A are slightly lower than those  
 371 in Type B with an average of 0.41 and 0.47, respectively.

372  
 373 **Figure 4.** An example of the derivation of  $\text{N}_2\text{O}_5$  uptake coefficient and  $\text{ClNO}_2$  yield constrained by

374 observation of aerosol surface area,  $\text{N}_2\text{O}_5$  and the enhancement of particulate nitrate and  $\text{ClNO}_2$  on  
 375 5<sup>th</sup> November, 2019. The pink region presents  $\pm 50\%$  uncertainty of  $\text{N}_2\text{O}_5$  uptake coefficient.

376 **Table 4.** The derived  $\text{N}_2\text{O}_5$  uptake coefficient and  $\text{ClNO}_2$  yields at each night.

NO.	Period	$\gamma\text{N}_2\text{O}_5$ <sup>a</sup>	$\varphi\text{ClNO}_2$ <sup>a</sup>	$\varphi\text{ClNO}_2$ <sup>b</sup>	$r^2$ <sup>b</sup>	Type

20	11/13 21:00-00:00	0.0070	0.70	0.75	0.92	B

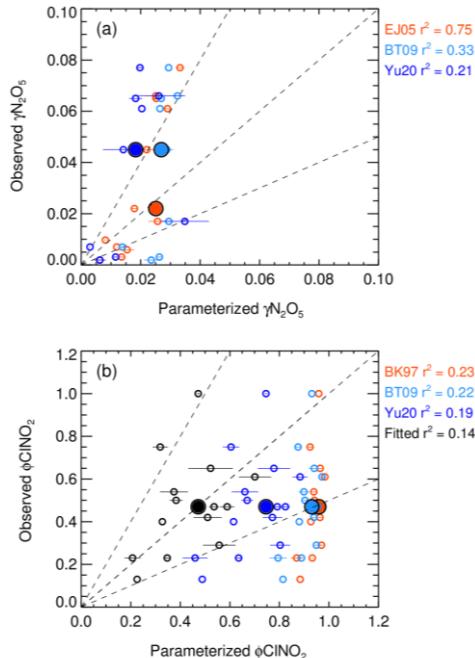

377 Note: <sup>a</sup> the values of  $\gamma\text{N}_2\text{O}_5$  and  $\varphi\text{ClNO}_2$  are derived by simulation method; <sup>b</sup> the  $\varphi\text{ClNO}_2$  and the  
 378 correlation coefficient ( $R^2$ ) between  $\text{ClNO}_2$  and particulate nitrate are derived by regression method,  
 379 the data was filtered with a correlation coefficient obtained from linear fitting threshold of 0.5.

380 To gain insight into the factors governing the  $\text{N}_2\text{O}_5$  uptake and  $\text{ClNO}_2$  formation processes, the  
 381 estimated  $\gamma\text{N}_2\text{O}_5$  and  $\varphi\text{ClNO}_2$  were compared with those predicted from complex laboratory-derived  
 382 and field-derived parameterizations. An aqueous inorganic iconic reaction mechanism once raised by  
 383 Bertram and Thornton (2009) and established a volume-limited parameterization by considering the  
 384 aerosol volume, surface area, nitrate content, ALWC, and chloride content (named BT09, Eq. 8).

$$385 \gamma_{BT09} = \frac{4H_{aq}V^k}{CS_a} \left( 1 - \frac{1}{1 + \frac{k_3[H_2O]}{k_2b[N\text{O}_3]} + \frac{k_4[Cl^-]}{k_2b[N\text{O}_3]}} \right) \quad (8)$$

386 Where  $H_{aq}$  is Henry's law coefficient of  $\text{N}_2\text{O}_5$ ,  $V$  is the aerosol volume;  $k$  is equal to  $1.15 \times 10^6 - (1.15$

387  $\times 10^6)^{\exp(-0.13[H_2O])}$ ;  $k_3/k_{2b}$  is the ratio of reaction rate of  $H_2O$  versus  $NO_3^-$  to  $H_2ONO_2^+$  that was set to  
388 0.06, and  $k_4/k_{2b}$  is the ratio of reaction rate of  $Cl^-$  versus  $NO_3^-$  to  $H_2ONO_2^+$  that was set to 29  
389 (Bertram and Thornton, 2009). The mean values of particulate volume to surface ratio (V/Sa) was  
390 measured. A simple parameterization (EJ05) considered the effect of enhanced RH and temperature  
391 on  $N_2O_5$  uptake was also included (Evans and Jacob, 2005). In addition, the recently established  
392 empirical parameterization based on the same framework (Eq. 8, named Yu20), optimized some  
393 parameters according to the meta-analysis of five field measurements in China by Yu et al. (2020),  
394 also assessed in the study. Figure 5(a) shows the correlation of estimated  $\gamma N_2O_5$  versus the  
395 parameterization. All the three parameterizations fail to predict the high values. The simple  
396 parameterization of EJ05 had the best performance with a high correlation and a consistent  
397 prediction of the median value. While other two parameterizations, BT09 and Yu20, underestimated  
398 the observed  $\gamma N_2O_5$ . Figure 6(a-h) show the dependence of the observed  $\gamma N_2O_5$  on the factors  
399 reported in previous literatures that possibly alert the processes of  $N_2O_5$  uptake and  $CINO_2$  formation.  
400 We show that  $\gamma N_2O_5$  highly correlated with the ambient RH as well as liquid water content,  
401 confirming the critical role of water content in  $N_2O_5$  uptake and explained the reason why EJ05 had a  
402 good performance. The dependence of  $\gamma N_2O_5$  on nitrate mass concentration does not follows the rule  
403 of nitrate suppressing effect (Wahner et al., 1998), which may be due to the covariance of nitrate and  
404 liquid water content. With respect to other factors, insignificant impacts on the  $N_2O_5$  uptake are  
405 obtained.

406

407 **Figure 5.** The inter-comparison of observation and parameterization of  $\text{N}_2\text{O}_5$  uptake coefficient (a)  
408 and  $\text{ClNO}_2$  yield (b). The larger size of solid dots represents the median results. The parametrizations  
409 of EJ05, BT09, Yu20 and BK97 cited from Evans and Jacob (2005), Bertram and Thornton (2009),  
410 Yu et al. (2020), Behnke et al. (1997), respectively. The fitted  $\text{ClNO}_2$  yield (colored by black) in  
411 panel (b) shows the best fitting result in the study by adopting the  $k_4/k_3$  of 32.0.

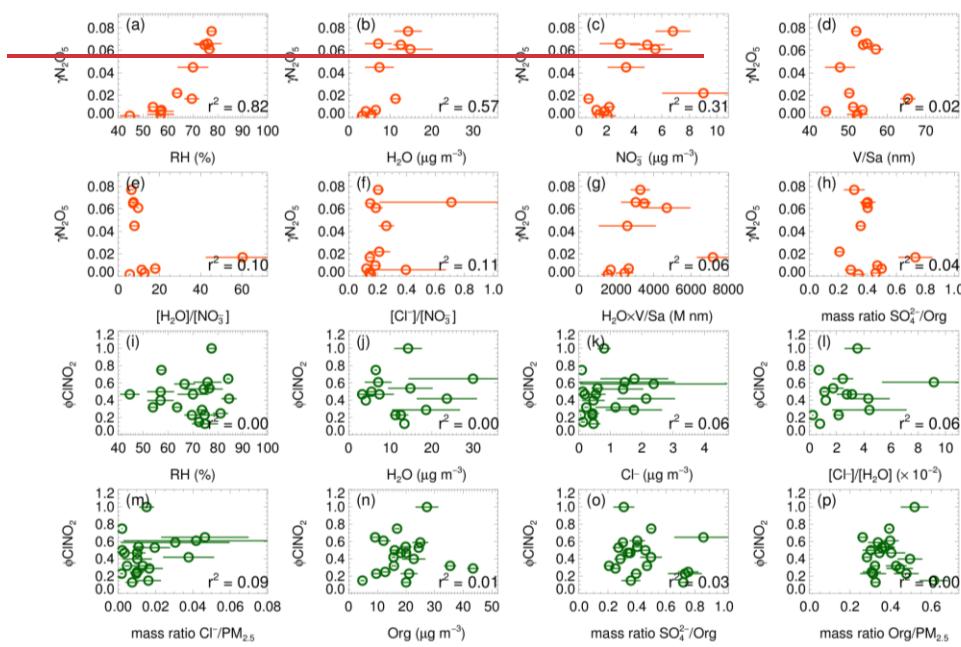

412 Bertram and Thornton (2009) also proposed a  $\text{ClNO}_2$  yield parameterization method that  
413 considering the ratio of ALWC and chloride content (Eq. 9), here the  $k_4/k_3$  was the ratio of reaction  
414 rate of  $\text{H}_2\text{ONO}_2^+$  versus  $\text{Cl}^-$  to  $\text{H}_2\text{O}$  and adopted as  $483 \pm 175$ . Behnke et al. (1997) determined this  
415 ratio of  $836 \pm 32$ , while it is estimated to be  $105 \pm 37$  in Yu et al. (2020).

416 
$$\varphi_{BT09} = \left( \frac{[\text{H}_2\text{O}]}{1+k_4/k_3[\text{Cl}^-]} \right)^{-1} \quad (9)$$

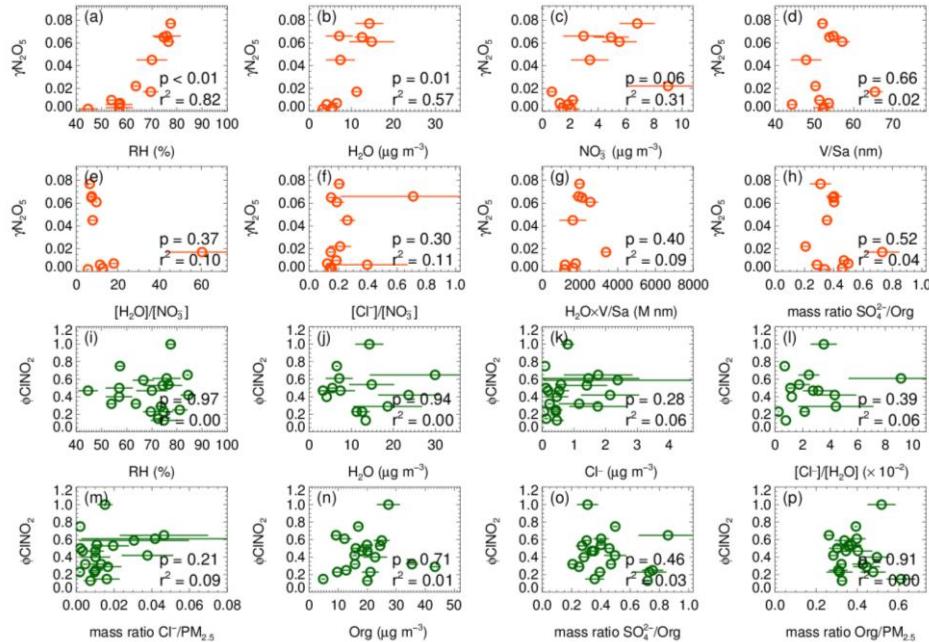

417 Figure 5(b) shows that all the predicting  $\text{ClNO}_2$  yield based on the abovementioned  
418 parameterizations overestimated the observations. The performance of the parameterization schemes  
419 of BK97 and BT09 based on the model aerosol conditions with an overestimation up to  $\sim 100\%$  are  
420 expected and consistent with previous studies, which may be caused by the unaccounted potentially  
421 competitive effect of other species like organics, sulfate for the  $\text{NO}_2^+$  intermediate (McDuffie et al.,

设置了格式: 上标

422 2018a; Staudt et al., 2019; Xia et al., 2021; Wang et al., 2017d). Although the empirical  
 423 parameterization (Yu20) based on field observations improved the prediction and narrowed the gap  
 424 effectively, the overestimation is still large with an average of ~50%, which indicated that the yield  
 425 are more strongly suppressed [in this study](#) than those observed in the campaigns of Yu et al. (2020).  
 426 The factor 32.0 ( $k_4/k_3$  in Eq. 9) was derived by iterative algorithms to achieve the best consistent  
 427 between the observed and parameterized  $\text{ClNO}_2$  yield, which is smaller than the Yu20 parameters by  
 428 factors of 3.3. We examined the relationships of  $\text{ClNO}_2$  yields with aerosol water content and other  
 429 aerosol compositions as shown in Figure 6(i-p). We show that  $\varphi\text{ClNO}_2$  only weakly correlated with  
 430 the content of chloride (including the mass ratio and fraction in  $\text{PM}_{2.5}$ ) and the molar ratio of chloride  
 431 to water, confirmed the dependence found in laboratory studies. However, we did not find the  
 432 dependence of the yields with aerosol organic or sulfate, as well as the RH and water alone in the  
 433 campaign, implying the  $\text{ClNO}_2$  yield mechanism is much more complicated than the laboratory  
 434 conditions.

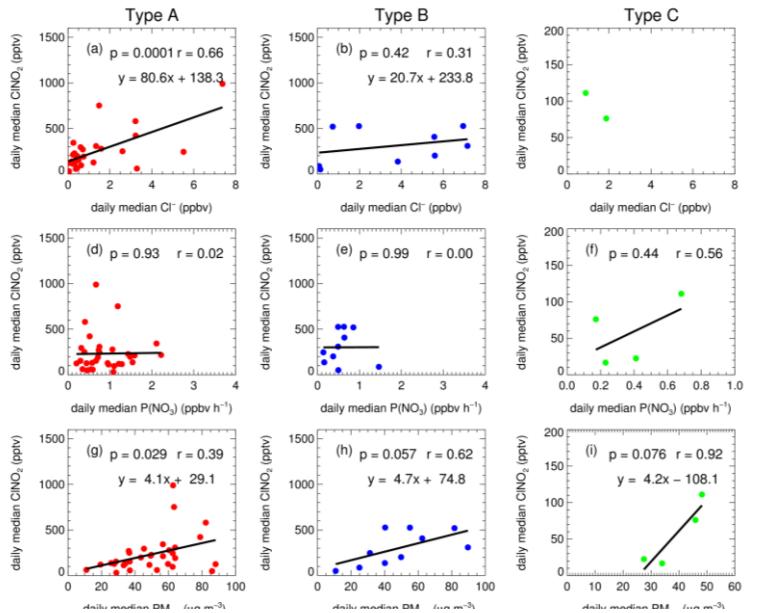

435

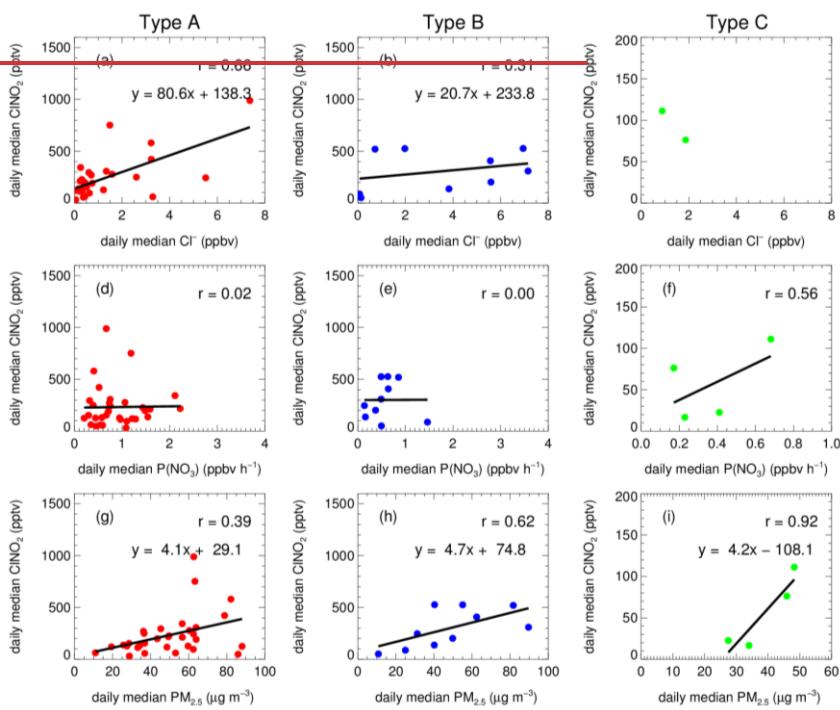

436 **Figure 6.** The estimated  $\text{N}_2\text{O}_5$  uptake coefficient and  $\text{ClNO}_2$  yield versus related parameters.

438 **3.4 The factors influence  $\text{ClNO}_2$  formation**

439 The  $\text{ClNO}_2$  formation can be largely affected by the budget of  $\text{NO}_3\text{-N}_2\text{O}_5$  and  $\text{N}_2\text{O}_5$  uptake processes.  
440 The variation of  $\text{NO}_3$  loss by VOC and NO alert the  $\text{NO}_3$  loss distribution by  $\text{N}_2\text{O}_5$  uptake and  
441  $\text{ClNO}_2$  formation indirectly. Figure 7 shows the correlation between daily median  $\text{ClNO}_2$  and mass  
442 concentration of chloride,  $\text{PM}_{2.5}$  and  $\text{NO}_3$  production rate for the three types of air masses. Due to the  
443 limited dataset of type C, the correlation analysis may not make sense, therefore, we did not take  
444 type C into consideration in detailed discussion. We show that the mass concentration of chloride  
445 also showed a correlation coefficient with  $\text{ClNO}_2$  by 0.66 and 0.31 for type A and B, respectively.  
446 Furthermore, the mass concentration of  $\text{PM}_{2.5}$  correlated reasonably with the  $\text{ClNO}_2$  formation with  
447 the correlation coefficient of 0.39 and 0.62 for type A and B, respectively. But, the levels of  $\text{ClNO}_2$   
448 demonstrate little relationship with the nitrate production rate. This is quite different from the results  
449 observed in United Kingdom, where the  $\text{ClNO}_2$  levels are mainly controlled by  $\text{NO}_2$  and  $\text{O}_3$ , rather  
450 than by the  $\text{N}_2\text{O}_5$  uptake processes (Sommariva et al., 2018).

451

452

453 **Figure 7.** The functional dependence of daily median of  $\text{ClNO}_2$  on particulate chloride, nitrate  
454 radical production rate and  $\text{PM}_{2.5}$  in the air mass of Type A (a, d, g), Type B (b, e, h) and Type C (c, f,  
455 i).

456 The low correlation between  $\text{ClNO}_2$  and  $\text{NO}_3$  production rate is within expectations. In general,  
457 the production of nitrate radical controls the total budget of  $\text{N}_2\text{O}_5$ , if  $\text{N}_2\text{O}_5$  uptake dominated the sink  
458 of  $\text{NO}_3$ , as the result the  $\text{N}_2\text{O}_5$  uptake and its products would show good correlation with  $\text{NO}_3$   
459 production rate. But in fact,  $\text{NO}_3$  loss can also be affected by other loss pathways, like the reactions  
460 with NO and VOCs. In many cases, the  $\text{NO}_3$  loss is dominated by VOC or NO, that means the  
461  $\text{ClNO}_2$  formation is suppressed. If the two loss pathways are highly varied due to irregular emissions,  
462 then the relationship between  $\text{ClNO}_2$  and  $\text{NO}_3$  production rate would be less correlated. We  
463 confirmed large variations of NO and VOC (not shown) in hourly and daily scales, which means the  
464 proportion of  $\text{N}_2\text{O}_5$  uptake to the total loss of  $\text{NO}_3$  is highly varied correspondingly. In addition, the  
465 variation of  $\text{N}_2\text{O}_5$  uptake coefficient and  $\text{ClNO}_2$  yield also result in the weak correlation between  
466  $\text{NO}_3$  production rate and  $\text{ClNO}_2$  concentration. The weak correlation reflects the highly variable  
467 chemical processes from  $\text{NO}_3$  production to  $\text{ClNO}_2$  production in this region. Overall, the low  
468 correlation in the study indicated that the  $\text{ClNO}_2$  formation through  $\text{N}_2\text{O}_5$  uptake is not limited by  
469  $\text{NO}_3$  formation processes, at least in Type A and B. With respect to the air mass Type C,  $\text{ClNO}_2$   
470 showed correlation with  $\text{P}(\text{NO}_3)$  with the correlation coefficient of 0.56.

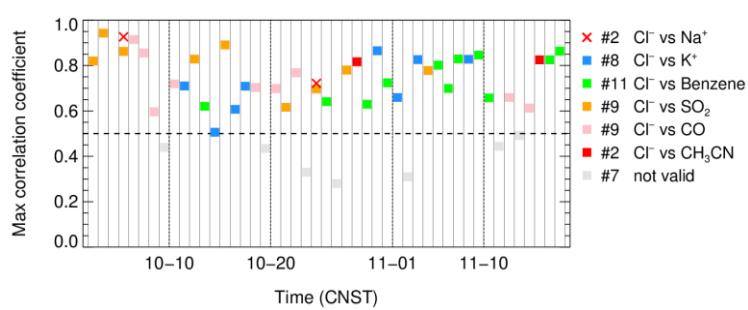

471 As the precursor of  $\text{ClNO}_2$ , higher concentrations of particulate chloride result in high  $\text{ClNO}_2$   
472 yield from  $\text{N}_2\text{O}_5$  uptake to some extent, as evidenced by our field observation (Figure 6) and  
473 previous laboratory studies (Bertram and Thornton, 2009; Roberts et al., 2009; Ryder et al., 2015).  
474 High  $\text{PM}_{2.5}$  concentrations usually provide more aerosol surface area to promote  $\text{N}_2\text{O}_5$  uptake. The  
475 close relationship between  $\text{ClNO}_2$  and  $\text{PM}_{2.5}$  indicate that aerosol surface area, most likely, is a  
476 critical factor that limited  $\text{ClNO}_2$  formation. The proportion of nitrate in the total  $\text{PM}_{1.0}$  was small  
477 with an average of 10.4%, therefore the correlation of  $\text{ClNO}_2$  and  $\text{PM}_{2.5}$  cannot attribute to the  
478 covariance between nitrate and  $\text{PM}_{2.5}$ . In addition, the  $\text{ClNO}_2$  level in the air mass of Type B show  
479 higher correlation to both  $\text{Cl}^-$  and  $\text{PM}_{2.5}$  than type A, suggesting that the  $\text{ClNO}_2$  formation in Type B  
480 is more effectively affected by the levels of chloride and  $\text{PM}_{2.5}$ .

481 Recently model simulation indicated that the  $\text{ClNO}_2$  chemistry level is sensitive to the emission of  
482 chloride in PRD (Li et al., 2021). In this study, a question raised that where is the source of chloride?  
483 The mass ratio of  $\text{Cl}^-/\text{Na}^+$  is often used as an indicator of sea salt or anthropogenic sources to  
484 chloride with a threshold of 1.81 (Yang et al., 2018; Wang et al., 2016). High ratio means the  
485 particulate chloride affected by anthropogenic emission rather than sea salt. We determine that the

设置了格式: 下标  
设置了格式: 下标

486 mean mass ratios of  $\text{Cl}^-$  to  $\text{Na}^+$  are 5.3, 6.3 and 3.1 in Type A, B and C, respectively (Figure 3). This  
 487 indicated that  $\text{PM}_{2.5}$  sampled during the campaign was not strongly influenced by fresh sea salt  
 488 aerosols. In the three types, the Type C air mass had a lowest ratio and may be influenced by both sea  
 489 salt and anthropogenic emissions, which seems reasonable since it come from South China Sea. If  
 490 we assume that Type A air mass is free of sea salt and only influenced by anthropogenic activities,  
 491 the higher ratio implies more intensive chloride source in Type B. The correlation between  
 492 particulate chloride and some possible indicators, including  $\text{K}^+$ , benzene,  $\text{SO}_2$ , CO, acetonitrile  
 493 ( $\text{CH}_3\text{CN}$ ), were examined day by day. Figure 8 shows the max correlation coefficient ( $R^2$ ) in each  
 494 day with a threshold of 0.5. We filtered out 39 out of 46 days during this campaign with a fraction of  
 495 85%. Among the 39 days, a total of 11 days is associated with strongest correlation between  $\text{Cl}^-$  and  
 496 benzene, which is typically come from industrial emissions.  $\text{Cl}^-$  also correlated with  $\text{K}^+$ , CO and  
 497  $\text{CH}_3\text{CN}$  in 19 day in total, implies potential contributions from biomass burning emissions. In total of  
 498 9 days for highest correlations of  $\text{Cl}^-$  with  $\text{SO}_2$  indicated coal-fired power plants emissions may also  
 499 contributed to  $\text{Cl}^-$  emission. We summarized that the source of chloride may be highly varied from  
 500 different anthropogenic activities including biomass burning, industrial processes as well as coal-  
 501 fired power plants. The statistic results in Table 5 suggest that the  $\text{Cl}^-$  in air mass of Type A were  
 502 affected by various sources, especially related to the sources associated with  $\text{K}^+$ , benzene and  
 503  $\text{CH}_3\text{CN}$ ; the  $\text{Cl}^-$  in Type B was mainly contributed by the similar source of CO, and Type C was only  
 504 affected by coal-fired power plants emissions. In addition, Figure 8 showed that there are 2 days that  
 505 the correlations between  $\text{Cl}^-$  and  $\text{Na}^+$  exceeded the max of the selected anthropogenic factor matrix,  
 506 indicated that the aerosol still also impacted by sea salt to some extent.

507

508 **Figure 8.** The max correlation coefficient between particulate chloride and a selected parameter  
 509 matrix (including  $\text{K}^+$ , benzene,  $\text{SO}_2$ , CO, acetonitrile ( $\text{CH}_3\text{CN}$ )) in each day. The labelled number in  
 510 each legend indicates the days be the maximum, the dashed line denotes the threshold of 0.5 (39  
 511 valid days out of 46 in total). The cross means the correlation coefficient between  $\text{Cl}^-$  and  $\text{Na}^+$  is

512 larger than the max.

513 **Table 5.** The statistic of the days for highest factors correlated with particulate chloride in different  
514 air mass pattern.

Factors	Type A	Type B	Type C
K <sup>+</sup>	8	0	0
Benzene	9	2	0
SO <sub>2</sub>	5	1	3
CO	4	5	0
CH <sub>3</sub> CN	2	0	0

515 **3.5 The impacts of ClNO<sub>2</sub> on atmospheric oxidation**

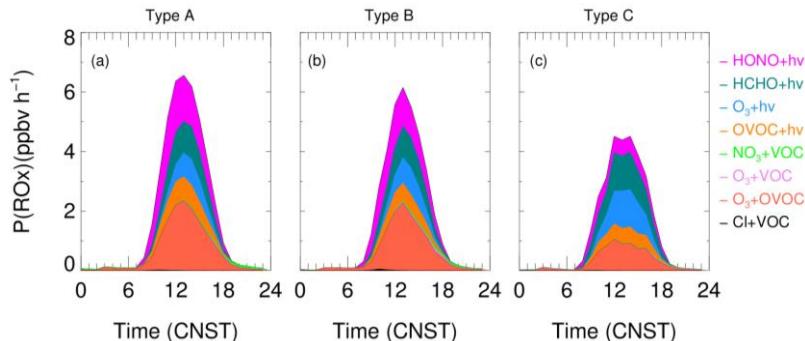

516 In this section, we focus on the assessment of the impact of ClNO<sub>2</sub> photolysis on the source of  
517 radicals and the contribution to the atmospheric oxidation. Figure 9 shows the diurnal accumulation  
518 of ROx production rate from model simulations with ClNO<sub>2</sub> chemistry in the three types of air mass.  
519 The total ROx production rate was higher in Type A and then followed by Type B and C, in which  
520 photolysis of HONO, HCHO, O<sub>3</sub> and OVOCs had large contributions. In addition, we noticed that  
521 the significant role of OVOCs (including photolysis and reacts with O<sub>3</sub>) in producing ROx at this site,  
522 especially in the Type A and B air mass. This result is consistent with that constrained by observed  
523 OVOCs in Guangzhou City (Wang et al., 2022c).

524 Cl radical, liberated by ClNO<sub>2</sub>, enhanced little ROx production, with a morning peak contribution of  
525 1.3%, 2.2% and 1.8% for Type A, B, C, respectively (08:00-09:00). The contribution of ClNO<sub>2</sub>  
526 photolysis to the production of ROx is less than 1% on daytime averaged, similar to the results  
527 obtained in winter Shanghai (Lou et al., 2022) as well as North China (Xia et al., 2021), and much  
528 lower compared to previous studies reported in summer time in both north and south China (Tan  
529 et al., 2017; Tham et al., 2016). However, another winter campaign conducted in Hongkong in winter  
530 showed much more significant impacts compared with our observation (Wang et al., 2016), indicated  
531 that the ClNO<sub>2</sub> chemistry can also had a large influence on the radical formation in wintertime.

设置了格式: 下标

532 (Tham et al., 2016; Wang et al., 2016) In addition, we noticed that the significant role of OVOCs  
533 (including photolysis and reacts with O<sub>3</sub>) in producing ROx at this site, especially in the Type A and  
534 B air mass. This result is consistent with that constrained by observed OVOCs in Guangzhou City  
535 (Wang et al., 2022c).

536

537 **Figure 9.** The diurnal cycle and distribution of ROx production rate in the three types air masses.

538 Figure 10 shows the enhancement of OH, HO<sub>2</sub> and RO<sub>2</sub> radicals with the consideration of CINO<sub>2</sub> chemistry. The enhancement of the three radicals peaked in the morning. On average, OH concentration was enhanced by 1.5% to 2.6% in different air masses. The percentage of enhancement for HO<sub>2</sub> radical was 1.9% to 4.6%, whereas the enhancement for RO<sub>2</sub> was a little bit higher (3.0% to 540 6.8%). In general, the enhancement of radicals was more significant in Type B than other two types 541 of air masses, which is related to elevated CINO<sub>2</sub> concentrations for these air masses. Low CINO<sub>2</sub> 542 and other radical precursors led to an earlier enhancement peak (08:00-09:00) in Type C and lasted a 543 short time period. Although the increase peak occurred later at 09:00-10:00 for the air mass of Type 544 A and Type B, the increase lasted for a longer time and had a longer effect. Overall, daytime OH, 545 HO<sub>2</sub> and RO<sub>2</sub> enhanced by 1.0%, 2.0%, and 3.0% on campaign average.

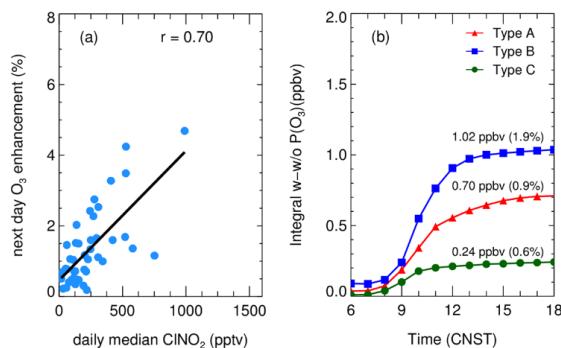

548

549 **Figure 10.** The diurnal cycle on the enhancement of OH (a), HO<sub>2</sub> (b), RO<sub>2</sub> (c) by CINO<sub>2</sub> chemistry 550 in the three air mass patterns.551 Figure 11 depicts the integral enhancement of O<sub>3</sub> production by CINO<sub>2</sub> photolysis varied from less

552 than 0.1 ppb to 4 ppb day by day, with a percentage of <1% to 4.9% with a median of 0.8%. Our  
553 results are comparable with the winter case in North China (Xia et al., 2021). The next day O<sub>3</sub>  
554 enhancement was highly correlated with the level of CINO<sub>2</sub> with the correlation coefficient of 0.7  
555 (Fig. 11(a)). The daily net O<sub>3</sub> production enhanced by 0.70 ppbv  $\text{h}^{-1}$  (0.9%), 1.02 ppbv  $\text{h}^{-1}$  (1.9%),  
556 0.24 ppbv  $\text{h}^{-1}$  (0.6%) on daytime accumulation in Type A, B, C, respectively, which is consistent with  
557 the nocturnal level of CINO<sub>2</sub> in the three air masses presented in Table 3.

558

带格式的: 段落间距段前: 0 磅

559

560 **Figure 11.** (a) The correlation of daily median CINO<sub>2</sub> (18:00-06:00) and its impact on next day net  
561 O<sub>3</sub> production enhancement during the campaign; (b) the average contribution of daytime integral O<sub>3</sub>  
562 by CINO<sub>2</sub> mechanism in the three types of air masses.

563 Table 6 summarized the observation-constrained box model simulation results about the impacts  
564 of CINO<sub>2</sub> chemistry. The average CINO<sub>2</sub> concentration in the observation is moderate compared with  
565 previous observations, other radical precursors (e.g., HCHO) also elevated at the same time. This  
566 leads to a large total radical and ozone production rate and relative minor contribution by CINO<sub>2</sub>  
567 chemistry. Which indicates that the contribution of CINO<sub>2</sub> chemistry is affected by the budget of  
568 other radical precursors. In addition, significant contribution by CINO<sub>2</sub> chemistry to photochemical  
569 pollution also frequently observed in different campaigns (Tham et al., 2016; Wang et al., 2016), in  
570 which the receptor site may have aging plumes with higher CINO<sub>2</sub> and thus larger contributions  
571 (Wang et al., 2016), suggests the large variability of CINO<sub>2</sub> and its environmental impacts at various  
572 air masses. Here, our observations should be representative of the local condition and reflects the  
573 chemistry and impacts of CINO<sub>2</sub> on the air pollutions in PRD region.

574 **Table 6.** The summary of impacts of CINO<sub>2</sub> on the next-day enhancement of ozone and radical  
575 production based on box model that constrained by field observations in previous literatures.

 579 contribution.

580

581 Previous studies suggest that chlorine radicals from ClNO<sub>2</sub> photolysis may contribute significantly  
 582 to the oxidation of some VOCs species, especially for long-chain alkanes (Shi et al., 2020; Wang et  
 583 al., 2022b). The oxidation of long-chain alkanes (C10~14 n-alkanes) by chlorine and OH  
 584 radicals during the morning hour (0809:00—0910:00) were also evaluated based on modeled  
 585 oxidants concentration. We observe small contributions of chlorine radical with a percentage of 4.3%,  
 586 4.3% and 3.8% for n-decane, n-dodecane, and n-tetradecane, respectively, during the period (Oct.  
 587 16<sup>th</sup> to Nov. 17<sup>th</sup>, 2019) when the long-chain alkanes measurement was valid. We also checked the  
 588 role of chlorine radicals in short-chain alkanes oxidation, obtaining a slightly larger contribution than  
 589 the long-chain alkanes, which is attributed to a relatively larger reaction rate constants between Cl  
 590 with OH with respect to the short-chain alkanes. The daytime average contributions of Cl ranged  
 591 from 1.4% - 1.6% varied by the chain length of the alkanes. Therefore, we concluded that chlorine  
 592 radicals liberated by ClNO<sub>2</sub> photolysis play a role in the oxidation of alkanes in the morning time,  
 593 but are not critical compared with OH oxidation on the daytime average. We note that several studies  
 594 reported other sources produced a large number of halogen radicals like Cl<sub>2</sub> (Liu et al., 2017; Xia et  
 595 al., 2020), BrCl (Peng et al., 2021), the daytime reaction of HCl with OH (Riedel et al., 2012; Eger et  
 596 al., 2019; Li et al., 2019). These may cause more alkanes oxidized by halogen radicals. However, it is  
 597 not possible to assess the overall impacts by constraining all precursors of chlorine radical in this  
 598 work, which may warrant further investigation by more comprehensive field studies equipped with  
 599 the instruments for detecting these species.

600 We observe small contributions of chloride radicalchlorine radical with a percentage of 3.2%, 3.7%  
601 and 4.2% for n-decane, n-dodecane and n-tetradecane, respectively. The contributions reduced to <1%  
602 on daytime average. We also checked the role of chloride chlorine radicals in short chain alkanes  
603 oxidation, obtaining an even smaller contribution than the long chain alkanes. The contributions  
604 reduced to <1% on daytime average. Therefore, we concluded that, chloride radicalchlorine radicals  
605 liberated by  $\text{CINO}_2$  photolysis, is not critical to the oxidation of alkanes compared with OH oxidation  
606 during the campaign. We note that several studies reported other sources produced large amount of  
607 chloride radical halogen radicals like  $\text{Cl}_3$  (Liu et al., 2017; Xia et al., 2020),  $\text{BrCl}$  (Peng et al., 2021),  
608 the daytime reaction of  $\text{HCl}$  with OH (Riedel et al., 2012; Eger et al., 2019; Li et al., 2019),  $\text{Br}_2$  (Xia et  
609 al., 2022). However, it is not possible to assess the overall impacts by constraining all precursors of  
610 chloride radicalchlorine radical in this work, which may warrant further investigation by more  
611 comprehensive field studies equipped with the instruments for detecting these species.

#### 612 4. Conclusion

613 An intensive field study in Pearl River Delta took place during a photochemical pollution season  
614 from Sept. 26<sup>th</sup> to Nov. 17<sup>th</sup>, 2019, providing a comprehensive observation dataset to understand the  
615  $\text{CINO}_2$  chemistry and its impacts on the air quality. In general, we observed a wide variation for  
616 determining factors of  $\text{CINO}_2$  formation in different kinds of air masses. We found that the air  
617 masses highly varied from different regions and divided in three types according to the results of  
618 backward trajectory. Two of them, types of air mass from northern and northeastern inland cities and  
619 the eastern coastal regions, features polluted with elevated  $\text{O}_3$  and related trace gases like  $\text{NO}_x$  and  
620  $\text{CO}$ . Correlation analysis showed that  $\text{CINO}_2$  formation is limited by chloride availability and  $\text{PM}_{2.5}$   
621 concentrations (mostly due to aerosol surface area) at this site. In general, we observed a wide  
622 variation for determining factors of  $\text{CINO}_2$  formation in different kinds of air masses.

623 We estimated the  $\text{N}_2\text{O}_5$  uptake coefficients and  $\text{CINO}_2$  yield during this campaign and assessed the  
624 performance of previous parameterizations schemes. The newly developed observation-based  
625 empirical parameterization was also checked and showed an overall underestimation. We showed the  
626  $\gamma_{\text{N}_2\text{O}_5}$  only strongly correlated with RH, and the parameterization proposed by Evans and Jacob  
627 (2005) showed a considerable consistent with the observation. The  $\text{CINO}_2$  yield only showed weak  
628 correlation with the content of particle chloride, and the exist parameterizations systematically  
629 overestimated the yield.

630 The particulate chloride mainly originated from anthropogenic emissions rather than sea salt.  
631 However, the specific contributing source of chloride in this region cannot be determined, due to the  
632 varying correlation relationship with different kinds of anthropogenic emission indicators day by day.

633 ~~We can only infer that the air mass of Type A affected by most complicated anthropogenic emissions~~  
634 ~~including biomass burning, coal-fired power plants as well as the even possible usage of industrial~~  
635 ~~solvents.~~ This result highlights the  $\text{ClNO}_2$  chemistry may be triggered by many kinds of  
636 anthropogenic activities in the PRD regions (Wang et al., 2016; Yang et al., 2018). ~~The sources of~~  
637 ~~particulate chloride warrant further detailed exploration using the dataset along with other~~  
638 ~~observations in this region.~~

639 ~~In the end, we investigate the impacts of  $\text{ClNO}_2$  chemistry on atmospheric oxidation by a box~~  
640 ~~model. It is demonstrated that Observation-constrained box model revealed chloride radical chlorine~~  
641 ~~radicals~~ liberated by  $\text{ClNO}_2$  chemistry had a relatively small contribution to the following daytime  
642 level of  $\text{OH}$ ,  $\text{HO}_2$ , and  $\text{RO}_2\text{RO}_x$  radicals, as well as a small enhancement of and  $\text{O}_3$  and  $\text{RO}_x$   
643 production in all the three types of air masses in this region. The impacts of  $\text{ClNO}_2$  chemistry were  
644 larger in the Type B than that of Type A. Overall, the small contribution of  $\text{ClNO}_2$  chemistry in  
645 PRD region may be due to the limited  $\text{ClNO}_2$  produced by  $\text{N}_2\text{O}_5$  uptake processes, and other strong  
646 primary sources of radicals weakened its contribution indirectly. Given complex source of particulate  
647 chloride, we call for more field investigations to address the ~~chloride chemistry chlorine chemistry~~  
648 and its roles in air pollutions in China.

649 **Data availability.** The datasets used in this study are available from the corresponding author upon  
650 request (byuan@jnu.edu.cn).

651 **Author contributions.** H.C.W. and B.Y. designed the study. E.Z, X.X.Z. and H.C.W. operated and  
652 calibrated the CIMS, H.C.W. analyzed the data, H.C.W. and B.Y. wrote the manuscript with inputs  
653 from all coauthors.

654 **Competing interests.** The authors declare that they have no conflicts of interest.

655 **Acknowledgements.** This work was supported by the National Natural Science Foundation of China  
656 (grant No. 41877302, 42175111, 42121004), Guangdong Natural Science Funds for Distinguished  
657 Young Scholar (grant No. 2018B030306037), Key-Area Research and Development Program of  
658 Guangdong Province (grant No. 2019B110206001), and Guangdong Innovative and Entrepreneurial  
659 Research Team Program (grant No. 2016ZT06N263). This work was also supported by Special Fund  
660 Project for Science and Technology Innovation Strategy of Guangdong Province (Grant  
661 No.2019B121205004). The authors gratefully acknowledge the Jinan University science team for

662 their technical support and discussions during this campaign. We thank for the NOAA Air Resources  
663 Laboratory for providing the HYSPLIT model.

664 **Appendix**

665 **A1. The measurement background and calibration of CIMS**

666 The background measurement of ClNO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> was performed during the campaign. Figure 1A  
667 showed an example of the background check at the beginning of the campaign, which confirmed the  
668 negligible background signal in the measurement of ClNO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> in the ambient condition. The  
669 calibration of ClNO<sub>2</sub> measurement sensitivity has been introduced in Wang et al. (2022a). In brief, a  
670 nitrogen flow (6 mL min<sup>-1</sup>) containing 10 ppmv Cl<sub>2</sub> was passed over a slurry containing NaNO<sub>2</sub> and  
671 NaCl to produce ClNO<sub>2</sub> (Thaler et al., 2011), and NaCl was included in the slurry in order to  
672 minimize the formation of NO<sub>2</sub> as a byproduct. The mixed flow containing ClNO<sub>2</sub> was then  
673 conditioned to a given RH and sampled into the CIMS instrument. To quantify ClNO<sub>2</sub>, the mixed  
674 flow was delivered directly into a cavity attenuated phase shift spectroscopy instrument (CAPS,  
675 Model N500, Teledyne API) to measure background NO<sub>2</sub> concentrations or through a thermal  
676 dissociation tube at 365 °C to fully decompose ClNO<sub>2</sub> to NO<sub>2</sub>, and the total NO<sub>2</sub> concentrations were  
677 then determined using CAPS. The differences in the measured NO<sub>2</sub> concentrations with and without  
678 thermal dissociation was equivalent to ClNO<sub>2</sub> concentrations. The CAPS instrument had a detection  
679 limit of 0.2 ppbv in 1 min for NO<sub>2</sub> and an uncertainty of ~10%. To calibrate CIMS measurements of  
680 N<sub>2</sub>O<sub>5</sub>, a humidity adjustable mixed flow containing stable N<sub>2</sub>O<sub>5</sub>, which was produced via O<sub>3</sub>  
681 oxidation of NO<sub>2</sub>, was sampled into the CIMS instrument to obtain a normalized humidity  
682 dependence curve of N<sub>2</sub>O<sub>5</sub>. While the concentration of N<sub>2</sub>O<sub>5</sub> source is not quantified due to the  
683 absence of a N<sub>2</sub>O<sub>5</sub> detector, so we delivered the N<sub>2</sub>O<sub>5</sub> source flow through a supersaturated sodium  
684 chloride solution to convert N<sub>2</sub>O<sub>5</sub> to ClNO<sub>2</sub> with a unit efficiency at 50% RH, which is a widely used  
685 method for the calibration of ClNO<sub>2</sub> by CIMS technique. The absolute N<sub>2</sub>O<sub>5</sub> sensitivity at ~~RH~~ 50%  
686 RH can be realized and then scaled to other humidity condition by the normalized N<sub>2</sub>O<sub>5</sub> sensitivity  
687 curve determined before. The sensitivity curves for N<sub>2</sub>O<sub>5</sub> and ClNO<sub>2</sub> to water content were shown in  
688 Figure A1A2. In this study, the sensitivity of the instrument was calibrated after the campaign. The  
689 main parameters (pressure, voltages, etc.) of the CIMS were checked every day and were relatively

stable, indicating that the CIMS is operating stably during the campaign.

Figure A2-A3 shows the high-resolution peak fitting results of typical mass spectra at m/z 235 and m/z 208 for  $\text{N}_2\text{O}_5$  and  $\text{ClNO}_2$  in three air mass patterns, respectively. The peaks of  $\text{N}_2\text{O}_5$  and  $\text{ClNO}_2$  were clearly resolved in the mass spectra. The peak of  $\text{IN}_2\text{O}_5^-$  can be well retrieved by separating a large adjacent peak of  $\text{C}_2\text{H}_4\text{IO}_3\text{S}^-$  in the air masses affected by marine emissions (Type B and C), which might be hydroperoxymethyl thioformate (HPMTF) from dimethyl sulfide oxidation (Veres et al., 2020). The interference signals including  $\text{H}_3\text{INO}_2\text{S}^-$  for  $\text{ClNO}_2$  measurements can also be well separated in all the three air mass patterns. These results underline the necessity and feasibility in the application of ToF analyzer in detecting  $\text{N}_2\text{O}_5$  and  $\text{ClNO}_2$  with iodide CIMS.

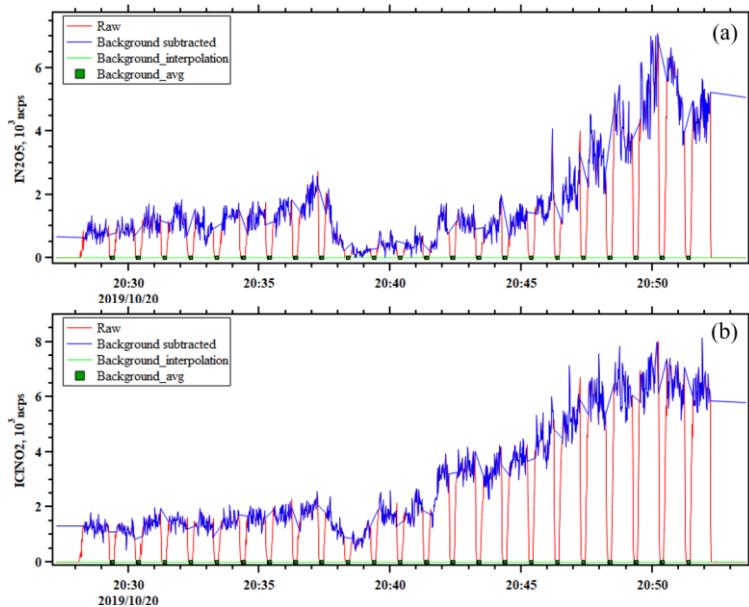

Figure A1. An example of background measurement for  $\text{N}_2\text{O}_5$  (a) and  $\text{ClNO}_2$  (b) in October 20<sup>th</sup>, 2019.
