22

23 **Abstract**

24 Clouds affect the Earth climate with an impact that depends on the cloud nature (solid/
25 liquid water). Although the Antarctic climate is changing rapidly, cloud observations are sparse
26 over Antarctica due to few ground stations and satellite observations. The Concordia station is
27 located on the East Antarctic Plateau (75°S, 123°E, 3233 m above mean sea level), one of the
28 driest and coldest places on Earth. We used observations of clouds, temperature, liquid water
29 and surface radiation performed at Concordia during 4 austral summers (December 2018-2021)
30 to analyse the link between liquid water and temperature and its impact on surface radiation in
31 the presence of supercooled liquid water (liquid water for temperature less than 0°C) clouds
32 (SLWCs). Our study has shown that, at the Concordia station, the very local structure of the ice
33 surface highly impacts the surface albedo and therefore the radiation budget. The ERA5 or
34 CERES data are not able to reproduce the diurnal variation of the local albedo. We established
35 that a two-sine empirical function with 24-h and 12-h periods well fits the BSRN observed
36 albedo. We show that ground-based observations are likely the best way to estimate the Net SR
37 in Concordia. Our analysis shows that, within SLWCs, temperature logarithmically increases
38 from -36.0°C to -16.0°C when liquid water path increases from 1.0 to 14.0 g m⁻², and SLWCs
39 positively impact the net surface radiation, which logarithmically increases by 0.0 to 50.0 W m⁻²
40 when liquid water path increases from 1.7 to 3.0 g m⁻². We finally estimate that SLWCs have
41 a great potential radiative impact over Antarctica whatever the season considered, up to 5.0 W
42 m⁻² over the Eastern Antarctic Plateau and up to 30 W m⁻² over the Antarctic Peninsula in
43 summer.

44

45 **1. Introduction**

46 Antarctic clouds play an important role in the climate system by influencing the Earth's
47 radiation balance, both directly at high southern latitudes and, indirectly, at the global level
48 through complex teleconnections (Lubin et al., 1998). However, in Antarctica, ground stations
49 are mainly located on the coast and yearlong observations of clouds and associated
50 meteorological parameters are scarce. Meteorological analyses and satellite observations of
51 clouds can nevertheless give some information on cloud properties suggesting that clouds vary
52 geographically, with a fractional cloud cover ranging from about 50 to 60% around the South
53 Pole to 80-90% near the coast (Bromwich et al., 2012; Listowski et al., 2019). In situ aircraft
54 measurements performed mainly over the Western Antarctic Peninsula (Grosvenor et al., 2012;
55 Lachlan-Cope et al., 2016) and nearby coastal areas (O'Shea et al., 2017) provided new insights
56 to polar cloud modelling and highlighted sea-ice production of Cloud-Condensation Nuclei and
57 Ice Nucleating Particles (see e.g. Legrand et al., 2016). Mixed-phase clouds (made of solid and
58 liquid water) are preferably observed near the coast (Listowski et al., 2019) with larger ice
59 crystals and water droplets (Lachlan-Cope, 2010; Lachlan-Cope et al., 2016; Grosvenor et al.,
60 2012; O'Shea et al., 2017; Grazioli et al., 2017). Based on the raDAR/liDAR-MASK
61 (DARDAR) spaceborne products (Listowski et al., 2019), it has been found that clouds are
62 mainly constituted of ice above the continent. The abundance of Supercooled Liquid Water
63 (SLW, the water staying in liquid phase below 0°C) clouds depends on temperature and
64 liquid/ice fraction. It decreases sharply poleward, and is two to three times lower over the
65 Eastern Antarctic Plateau than over the Western Antarctic. An important point remains the
66 inability of both research and operational weather prediction models to accurately represent the
67 clouds (especially SLW clouds, SLWCs) in Antarctica causing biases of several tens $W m^{-2}$ on
68 net surface radiation (Listowski and Lachlan-Cope, 2017; King et al., 2006, 2015; Bromwich
69 et al., 2013) over and beyond the Antarctic (Lawson and Gettelman, 2014; Young et al. 2019).

70 From year-long LIDAR observations of mixed-phase clouds at South Pole (Lawson and
71 Gettelman, 2014), SLWCs were shown to occur more frequently than in earlier aircraft
72 observations or weather model simulations, leading to biases in the surface radiation budget
73 estimates.

74 Liquid water in clouds may occur in supercooled form due to a relative lack of ice nuclei
75 for temperature greater than -39°C and less than 0°C . Very little SLW is then expected because
76 the ice crystals that form in this temperature range will grow at the expense of liquid droplets
77 (called the “Wegener-Bergeron-Findeisen” process; Wegener, 1911; Bergeron, 1928;
78 Findeisen, 1938; Storelvmo and Tan, 2015). Nevertheless, SLW is often observed at negative
79 temperatures higher than -20°C at all latitudes being a danger to aircraft since icing on the wings
80 and airframe can occur, reducing lift, and increasing drag and weight. As temperature decreases
81 to -36°C , SLW dramatically lessens, so it is highly difficult 1) to observe SLWCs and 2) to
82 quantify the amount of liquid water present in SLWCs. But during the Year Of Polar Prediction
83 (YOPP) international campaign, recent observations performed at the Dome C station in
84 Antarctica of 2 case studies in December 2018 have revealed SLWCs with temperature between
85 -20°C and -30°C and Liquid Water Path (LWP, the liquid water content integrated along the
86 vertical) between 2 to 20 g m^{-2} , as well as a considerable impact on the net Surface Radiation
87 (SR) that exceeded the simulated values by 20-50 W m^{-2} (Ricaud et al., 2020).

88 The Dome C (Concordia) station, jointly operated by French and Italian institutions in the
89 Eastern Antarctic Plateau ($75^{\circ}06'\text{S}$, $123^{\circ}21'\text{E}$, 3233 m above mean sea level, amsl), is one of
90 the driest and coldest places on Earth with surface temperatures ranging from about -20°C in
91 summer to -70°C in winter. There are three main instruments relevant to this study that have
92 been routinely running for about 10 years: 1) The H_2O Antarctica Microwave Stratospheric and
93 Tropospheric Radiometer (HAMSTRAD, Ricaud et al., 2010a) to obtain vertical profiles of
94 temperature and water vapour, as well as the LWP. 2) The tropospheric depolarization LIDAR

95 (Tomasi et al., 2015) to obtain vertical profiles of backscatter and depolarization to be used for
96 the detection of SLWCs. 3) The Baseline Surface Radiation Network (BSRN) station to
97 measure surface longwave (4–50 μm) and shortwave (0.3–3 μm), downward and upward
98 surface radiation (SR) from which the Net SR, calculated as the difference between the
99 downward and upward SRs, can be computed (Driemel et al., 2018) as:

$$100 \quad \text{Net} = \text{LWD} - \text{LWU} + \text{SWD} - \text{SWU} \quad (1)$$

101 where LWD, LWU, SWD and SWU correspond to Longwave Downward, Longwave Upward,
102 Shortwave Downward and Shortwave Upward SRs, respectively. Hereafter, we will use either
103 the term “radiative flux” or “radiation”, the latter consistent with the terminology presented
104 page 256 by Stull (1988).

105 The article is structured as follows. Section 2 presents the instruments during the period of
106 study. In section 3, we detail the methodology employed to detect the SLWCs and calculate
107 their impact on SR, and we present the statistical method to emphasize the relationship between
108 temperature and LWP on one hand, and SR and LWP on the other hand. The results are
109 highlighted in section 4 and discussed in section 5, before concluding in section 6.

110

111 **2. Instruments**

112 We have used the observations from 3 instruments held at the Dome C station, namely the
113 LIDAR instrument to classify the cloud as SLWC, the HAMSTRAD microwave radiometer to
114 obtain LWP and vertical profile of temperature, and the BSRN network to measure the SR
115 components: LWD, LWU, SWD and SWU to finally obtain the Net SR.

116 *2.1. LIDAR*

117 The tropospheric depolarization LIDAR (532 nm) has been operating at Dome C since 2008
118 (see http://lidarmax.altervista.org/englidar/_Antarctic%20LIDAR.php). The LIDAR provides
119 5-min tropospheric profiles of clouds characteristics continuously, from 20 to 7000 m above

120 ground level (agl), with a resolution of 7.5 m. For the present study, the most relevant parameter
121 is the LIDAR depolarization ratio (Mishchenko et al., 2000) that is a robust indicator of non-
122 spherical shape for randomly oriented cloud particles. A depolarization ratio below 10% is
123 characteristic of SLWC, while higher values are produced by ice particles. The possible
124 ambiguity between SLW droplets and oriented ice plates is avoided at Dome C by operating
125 the LIDAR 4° off-zenith (Hogan and Illingworth, 2003).

126 2.2. *HAMSTRAD*

127 *HAMSTRAD* is a microwave radiometer that profiles water vapour, liquid water and
128 tropospheric temperature above Dome C. Measuring at both 60 GHz (oxygen molecule line
129 (O₂) to deduce the temperature) and 183 GHz (H₂O line), this unique, state-of-the-art
130 radiometer was installed on site for the first time in January 2009 (Ricaud et al., 2010a and b).
131 The measurements of the *HAMSTRAD* radiometer allow the retrieval of the vertical profiles
132 of water vapour and temperature from the ground to 10-km altitude with vertical resolutions of
133 30 to 50 m in the Planetary Boundary Layer (PBL), 100 m in the lower free troposphere and
134 500 m in the upper troposphere-lower stratosphere. The time resolution is adjustable and fixed
135 at 60 seconds since 2018. Note that an automated internal calibration is performed every 12
136 atmospheric observations and lasts about 4 minutes. Consequently, the atmospheric time
137 sampling is 60 seconds for a sequence of 12 profiles and a new sequence starts 4 minutes after
138 the end of the previous one. The temporal resolution on the instrument allows for detection and
139 analysis of atmospheric processes such as the diurnal evolution of the PBL (Ricaud et al., 2012)
140 and the presence of clouds and diamond dust (Ricaud et al., 2017) together with SLWCs
141 (Ricaud et al., 2020). In addition, the LWP (g m⁻²) that gives the amount of liquid water
142 integrated along the vertical can also be estimated. Observations of LWP have been performed
143 when the instrument was installed at the Pic du Midi station (2877 amsl, France) during the
144 calibration/validation period in 2008 prior to its set up in Antarctica in 2009 (Ricaud et al.,

145 2010a) and during the Year Of Polar Prediction (YOPP) campaign in summer 2018-2019
146 (Ricaud et al., 2020). At the present time, it has not yet been possible to compare HAMSTRAD
147 LWP retrievals with observations from other instruments, neither at the Pic du Midi nor at
148 Dome C stations. To better evaluate its performance, the 2021-2022 and the future 2022-2023
149 summer campaigns are dedicated to in-situ observations of SLWCs. Comparisons with
150 numerical weather prediction models were showing consistent amounts of LWP at Dome C
151 when the partition function between ice and liquid water was favouring SLW for temperatures
152 less than 0°C (Ricaud et al., 2020). Note that microwave observations at 60 and 183 GHz are
153 not sensitive to ice crystals. This has already been discussed in Ricaud et al. (2017) when
154 considering the study of diamond dust in Antarctica. As a consequence, possible precipitation
155 of ice, within or below SLW clouds, as detected by the Lidar, does not affect the retrievals of
156 temperature, water vapour and liquid water.

157 2.3. BSRN

158 The BSRN sensors at Dome C are mounted at the Astroconcordia/Albedo-Rack sites, with
159 upward and downward looking, heated and ventilated Kipp&Zonen CM22 pyranometers and
160 CG4 pyrgeometers providing measurements of hemispheric downward and upward broadband
161 shortwave (SW, 0.3–3 μm) and longwave (LW, 4–50 μm) radiative fluxes at the surface,
162 respectively. These data are used to retrieve values of net surface radiation. All these
163 measurements follow the rules of acquisition, quality check and quality control of the BSRN
164 (Driemel et al., 2018).

165 2.4. Period of study

166 From the climatological study presented in Ricaud et al. (2020), the SLWCs are mainly
167 observed above Dome C in summer, with a higher occurrence in December than in January:
168 26% in December against 19% in January representing the percentage of days per month that
169 SLW clouds were detected during the YOPP campaign (summer 2018-2019) within the LIDAR

170 data for more than 12 hours per day. We have thus concentrated our analysis on December and
171 the 4 years: 2018-2021. Since we have to use the three data sets (LIDAR, HAMSTRAD and
172 BSRN) in time coincidence, the actual number of days per year selected in our analysis is
173 presented in Table 1.

174

175 **3. Methodology**

176 *3.1. SLWC detection and Surface Radiation Impact*

177 Consistent with Ricaud et al. (2020), we use LIDAR observations to discriminate between
178 SLW and ice in a cloud. High values of LIDAR backscatter coefficient ($\beta > 100 \beta_{\text{mol}}$, with β_{mol}
179 the molecular backscatter) associated with very low depolarization ratio ($< 5\%$) signifies the
180 presence of an SLWC whilst high depolarization ratio ($>20\%$) indicates the presence of an ice
181 cloud or precipitation. Once the SLWC is detected both in time and altitude, the regular
182 temperature (θ) profile within the cloud and the LWP measured by the HAMSTRAD
183 radiometer in time coincidence are selected together with the SR observed by the BSRN
184 instruments: Net, LWD, LWU, SWD and SWU SR.

185 The Lidar profiles are interpolated along the temperature vertical grid and then according
186 to the temperature time sampling. As a consequence, for a given time and height, we have a
187 depolarization ratio, a backscatter signal, a regular temperature and a (not height-dependent)
188 LWP. The same method is used for SR. BSRN SRs are time interpolated to be coincident with
189 the LWP values. So, for a given time, we have a set of BSRN SRs (Net, LWU, LWD, SWU
190 and SWD) and an LWP. At a (time, height) point showing high backscatter signal and low
191 depolarization, the associated parameters (regular temperature, LWP and SRs) are flagged as
192 “SLW cloud”. The statistic is thus done using all the SLW-flagged points without any
193 averaging. The temperature corresponds to the in-cloud temperature.

194 Figure 1 shows, as a typical example, the time evolution of the LIDAR backscatter
195 coefficient and depolarization ratio, as well as the HAMSTRAD LWP and temperature vertical
196 profile for the 27 December 2021. Associated with the SLWCs, the LWP increases with time
197 from 1.0 to 3.0 g m⁻². The SLWCs are present over a temperature range varying from
198 about -28.0 °C to -33.0 °C. Note the cloud present at 04:00-05:00 UTC that is not labelled as a
199 SLWC but rather as an ice cloud (high backscatter and high depolarization signals) with no
200 associated increase of LWP and temperature above -28.0 °C.

201 Figure 2 highlights the time evolution of the SLWC obtained on 27 December 2021
202 together with some snapshots from the HALO-CAM video camera taken with or without SLWC
203 on: 01:00 (no SLWC), 07:19 (SLWC), 09:00 (no SLWC), 10:14 (SLWC), 13:00 (no SLWC),
204 16:03 (SLWC), 18:01 (no SLWC) and 20:53 UTC (SLWC). SLWCs (high backscatter and low
205 depolarization signals) are clearly detected at 07:00-08:00, 10:00-11:00, 16:00-17:00, 21:00-
206 22:00 and 23:00-24:00 UTC over an altitude range 500-1000 m above ground level (agl). In
207 general, SLWCs observed over the station did not correspond to overcast conditions.

208 Over the 4 summers (December 2018-2021), we have selected 3 datasets in time
209 coincidence with SLWC: LWP, θ and SR. In order to estimate the impact of the SLWC onto
210 the SR, we calculated the anomaly of the daily SR with respect to the clear-sky SR associated
211 to the same day. Since it is impossible to measure for the same day the SR with and without
212 cloud, we have in priority looked for clear-sky days over the months of December in the 2018-
213 2021 period. Only 5 clear-sky days were selected on: 2 and 19 December 2018, and 3, 17 and
214 26 December 2021. These 5 days, considered as the reference SRs (SR_{Ref}), are presented in
215 Figure 3. We have also calculated (Figure 4) the time evolution of the clear-sky surface
216 radiation variability (δSR_{Ref}), namely the difference in SR observed by the BSRN instruments
217 between each of 5 clear-sky day and the corresponding values averaged over the 5 days, for
218 Net, LWD, LWU, SWD and SWU SR. The SR_{Ref} for the 5 days shown Figure 3 are all

219 consistent to each other with an obvious diurnal cycle in Net, LWD, LWU, SWD and SWU SR
 220 (we recall that in December there is a 24-h solar illumination at Dome C). The variability within
 221 the 5 days (δSR_{Ref}) shown Figure 4 is within $\pm 20 \text{ W m}^{-2}$ for the Net SR with a greater Net SR
 222 in 2018 than in 2021, within $\pm 35 \text{ W m}^{-2}$ for LWD and LWU SR (maxima on 17 December 2021
 223 and minima on 2 December 2018), and within $\pm 25 \text{ W m}^{-2}$ for SWD and SWU SR (maxima on
 224 26 December 2021 and minima on 2 December 2018).

225 Based on these 5 SR_{Ref} , we performed a systematic study over the 4-summer period by
 226 calculating the surface radiation anomaly ΔSR defined as:

$$227 \quad \Delta SR = SR - SR_{Ref} \quad (2)$$

228 for Net, LWD, LWU, SWD and SWU. As an example, we show in Figure 5 the time evolution
 229 for 27 December 2021 of the presence of the SLWC together with ΔSR calculated with respect
 230 to SR_{Ref} set to 26 December 2021. Associated with the SLWC, LWD and LWU ΔSR increase
 231 by 30-50 and 10-30 W m^{-2} , respectively, whilst SWD and SWU ΔSR decrease by 50-150 W m^{-2} ,
 232 respectively. The effect on the Net ΔSR is positive (10-100 W m^{-2}) at 07:00-08:00, 10:00-11:00,
 233 16:00-17:00 UTC and negative (from -30 to -100 W m^{-2}) at 21:00-22:00 and 23:00-24:00 UTC.
 234 Note that spikes appear in Net ΔSR , SWU ΔSR and SWD ΔSR mainly during scattered
 235 conditions and when large cloud episodes appear or disappear. They are real and can possibly
 236 come from the inhomogeneity of the cloud distribution. We thus want to statistically analyse
 237 all the ΔSR calculated in 2018-2021 with the 5 SR_{Ref} in order to check whether the net effect
 238 of the SLWC on the SR is positive or negative and to evaluate its sensitivity to liquid water
 239 amounts.

240 3.2. Statistical Method

241 The datasets are binned into 1°C -wide bins for θ , 0.2 g m^{-2} -wide bins for LWP, and
 242 5 W m^{-2} -wide bins for ΔSR . The number of points per bin is calculated for all the paired
 243 datasets, namely θ -LWP, and ΔSR -LWP (Net ΔSR -LWP, LWD ΔSR -LWP, LWU ΔSR -LWP,

244 SWD ΔSR -LWP and SWU ΔSR -LWP). The 2D probability density (PD) is calculated for the
 245 paired datasets and defined as $PD_{ij} = 100 \frac{N_{ij}}{N_t}$, where N_{ij} and N_t are the count number in the
 246 bin ij and the total count number ($N_t = \sum_{j=1}^N \sum_{i=1}^M N_{ij}$), respectively, with M and N being the
 247 total number of bins in LWP on one side, and in temperature or ΔSR on the other side,
 248 respectively. This study is focused on the evaluation of the LWP sensitivity for a given
 249 temperature and for a given radiation component (Net, LWD, LWU, SWD, SWU). So, for each
 250 value of θ_j (within a 1°C -wide bin j) or ΔSR_j (within a 5 W m^{-2} -wide bin j), a weighted average
 251 of LWP (\overline{LWP}_j) is calculated together with its associated weighted standard deviation (σ_{LWP_j}),
 252 considering all the LWP_{ij} values (within 0.2 g m^{-2} -wide bins) from $i=1$ to M , with M the total
 253 number of LWP bins and w_{ij} the weight, namely the number of points ($w_{ij} = N_{ij}$), associated
 254 to the bin ij :

$$255 \quad \overline{LWP}_j = \frac{\sum_{i=1}^M w_{ij} LWP_{ij}}{\sum_{i=1}^M w_{ij}} \quad (3)$$

256 and

$$257 \quad \sigma_{LWP_j} = \sqrt{\frac{\sum_{i=1}^M w_{ij} (LWP_{ij} - \overline{LWP}_j)^2}{\sum_{i=1}^M w_{ij}}} \quad (4)$$

258 For each θ and ΔSR dataset, the distribution of the total count numbers N_{tj} per 1°C or
 259 5 W m^{-2} -wide bin ($N_{tj} = \sum_{i=1}^M N_{ij}$ with $j = 1, \dots, N$) can be fitted by a function $N(x)$, with $x =$
 260 θ or ΔSR , based on 2 to 3 Gaussian distributions as:

$$261 \quad N(x) = \sum_{k=1}^{2 \text{ or } 3} a_k \exp\left(-\frac{1}{2} \left(\frac{x - \mu_k}{\sigma_k}\right)^2\right) + c \quad (5)$$

262 with a_k , μ_k and σ_k being the amplitude, the mean and the standard deviation of the k^{th} Gaussian
 263 function ($k = 1, 2$ or 3) and c is a constant. We have used $k = 2$ for ΔSR and $k = 3$ for θ . Table
 264 2 lists all the fitted parameters (a_k , μ_k , σ_k and c with $k = 1$ to 2 or 3).

265 In the relationship between x (θ or ΔSR) and LWP, we have considered x_j (θ_j or ΔSR_j) to
 266 be significant when:

$$267 \quad |x_j - \mu_k| \leq \sigma_k \text{ for } k = 1 - 2 \text{ (for } \Delta SR) \text{ or } 1 - 3 \text{ (for } \theta) \quad (6)$$

268 and used for this significant point its average value and standard deviation, $\overline{LWP_j}$ and σ_{LWP_j} ,
 269 respectively, with $j = 1, \dots, N$.

270 Finally, a logarithmic function of the form

$$271 \quad x = a + b \ln(\overline{LWP}) \quad (7)$$

272 has been fitted onto these significant points where the retrieved constants a and b are shown in
 273 Table 3 for x being θ , Net ΔSR , LWD ΔSR , LWU ΔSR , SWD ΔSR and SWU ΔSR .

274

275 **4. Results**

276 *4.1. Temperature-Liquid Water Relationship in Supercooled Liquid Water Clouds*

277 The relationship between temperature and LWP within SLWCs over the 4-summer period
 278 at Dome C is presented Figure 6 left in the form of a Probability Density that is the fraction of
 279 points within each bin of 0.2 g m^{-2} width in LWP and 1.0°C width in temperature. It clearly
 280 shows a net tendency for liquid water to increase with temperature, up to $\sim 14 \text{ g m}^{-2}$ in LWP and
 281 -18°C in temperature, with two zones having a density as high as $\sim 2\%$, at $[0.5 \text{ g m}^{-2}, -33^\circ\text{C}]$
 282 and $[1.5 \text{ g m}^{-2}, -32^\circ\text{C}]$. We have performed a weighted average of the LWPs within each
 283 temperature bin (Figure 6 centre). Then, we have fitted 3 Gaussian distributions to the count
 284 numbers as a function of temperature (Figure 6 right). If we now only consider temperature
 285 bins within one-sigma of the centre of the Gaussian distributions, we can fit the following
 286 logarithmic relation of the temperature θ as a function of LWP within the SLWC (Figure 6
 287 centre):

$$288 \quad \theta(LWP) = -33.8 (\pm 1.5) + 6.5 \ln(LWP) \quad (8)$$

289 for $\theta \in [-36; -16]$ °C and $LWP \in [1.0; 14.0]$ g m², where (± 1.5 °C) corresponds to the
 290 range where the relationship is valid within the 2 blue dashed lines in Figure 6 centre. In other
 291 words, based on our study, we have a clear evidence that supercooled liquid water content
 292 exponentially increases with temperature. Considering the temperature vs. LWP relationship,
 293 the 2 main Gaussian distributions are centred around -28°C and -30°C, corresponding to
 294 temperatures usually encountered in Concordia whilst the third one, far much less intense, is
 295 centred around -18°C, probably the signature of very unusual events occurring in Concordia as
 296 the warm-moist events. Episodes of warm-moist intrusions exist above Concordia originated
 297 from mid-latitudes (Ricaud et al., 2017 and 2020) and are known as “atmospheric rivers” (Wille
 298 et al., 2019). Although they are infrequent, they can provide high values of temperature and
 299 LWP.

300 *4.2. Impacts of Supercooled Liquid Water Clouds on Surface Radiation*

301 Although the amount of LWP is very low ($\ll 20$ g m²) at Dome C compared to what can
 302 be measured and modelled (Lemus et al., 1997) in the Arctic (50-75 g m²) and at
 303 middle/tropical latitudes (100-150 g m²), we intended to estimate its impact on the SR at Dome
 304 C. In Figures 7 to 9, the left panel presents the PDs (for bins of 0.2 g m² width in LWP and 5
 305 W m² width in ΔSR) of the surface radiation anomaly ΔSR as a function of the LWP, for Net,
 306 LWD, LWU, SWD and SWU, respectively. The central panel shows, for the same parameters,
 307 the corresponding weighted average LWP within 5 W m²-wide bins of radiation anomaly
 308 whereas the right panel shows the corresponding count number within 5 W m²-wide bins fitted
 309 by 2 Gaussian distributions.

310 Based on our analysis, the relationship between Net ΔSR (in W m²) and the LWP (in g m²)
 311 has been estimated from the HAMSTRAD and BSRN data as:

$$312 \quad \text{Net } \Delta SR(LWP) = -50.0 (\pm 10.0) + 90.0 \ln(LWP) \quad (9)$$

313 for $Net \Delta SR \in [-15; 50] \text{ W m}^{-2}$ and $LWP \in [1.5; 3.0] \text{ g m}^{-2}$, where ($\pm 10.0 \text{ W m}^{-2}$)
314 corresponds to the range where the relationship is valid within the 2 blue dashed lines in Figure
315 7 centre. Thus, for LWP greater than 1.7 g m^{-2} , our study clearly shows that there is a positive
316 impact of SLWC on the Net ΔSR that can reach 50 W m^{-2} for an LWP of 3.0 g m^{-2} .

317 The splitting of the net radiation anomaly between each of its four components can be
318 evaluated from their individual relationships with the LWP. These relations are gathered in
319 Table 3, established from the plots presented in Figures 7 to 9. They are of the same form as
320 for net surface radiation anomaly, i.e. a logarithmic dependence on LWP. Table 3 presents the
321 coefficients a and b of the logarithmic function $f(LWP) = a + b \ln(LWP)$ for the temperature
322 θ or the radiation components ΔSR , together with the valid range of these relations for $\theta, \Delta SR$
323 and LWP. For the values presented in Table 3, our study clearly shows that SLWCs have a
324 positive impact on LWD and LWU, with ΔSR increasing from 0 to 100 W m^{-2} and from 0 to
325 40 W m^{-2} for LWP ranging from 1.0 to 4.0 and from 1.6 to 2.5 g m^{-2} , respectively. Considering
326 the SR vs. LWP relationship, it seems that we have systematically one of the Gaussian
327 distributions centred around 0 W m^{-2} , reflecting the non-impacting part of SLWCs on SR
328 components.

329 Furthermore, our study also shows that SLWCs have a clear negative impact on SWD and
330 SWU, with ΔSR decreasing from 0 to -140 W m^{-2} and from 0 to -75 W m^{-2} with LWP ranging
331 from 1.2 to 3.8 and from 1.2 to 3.2 g m^{-2} , respectively.

332

333 **5. Discussion**

334 *5.1 Relation with critical temperature*

335 Note that the relationships show an exponential dependence of LWP on both temperature
336 and SR anomaly similar to the dependence of the molar volume and density of water on critical

337 temperature. As a matter of fact, the density ρ (g cm^{-3}) and molar volume ν ($\text{cm}^3 \text{mol}^{-1}$) of liquid
338 water are exponentially varying with temperature (Sippola and Taskinen, 2018):

$$339 \quad \rho = \rho_0 \exp\{-T_c(A + B\varepsilon + 2C\varepsilon^{1/2})\} \quad (13)$$

$$340 \quad \nu = \frac{M_{H_2O}}{\rho} = \frac{M_{H_2O}}{\rho_0} \exp\{T_c(A + B\varepsilon + 2C\varepsilon^{1/2})\} \quad (14)$$

341 where ρ_0 (g cm^{-3}), A (K^{-1}), B (K^{-1}), and C (K^{-1}) are parameters; T_c is the critical temperature
342 whose value varies from 227 to 228 K, and M_{H_2O} (g mol^{-1}) is the molecular weight of water.
343 ε (unitless) is defined as:

$$344 \quad \varepsilon = \frac{T}{T_c} - 1 \quad (15)$$

345 where T is temperature in K.

346

347 *5.2. Reference Surface Radiation and sastrugi effect*

348 In order to evaluate the surface radiation in clear-sky conditions at Concordia, we have
349 used, in complement to BSRN observations, and at the closest location to Concordia station,
350 two different data sets of surface radiations from i) the European Center for Medium-Range
351 Weather Forecasts Reanalysis version 5 (ERA5). ERA5 is a climate reanalysis dataset, covering
352 the period 1979 to present. ERA5 is being developed through the Copernicus Climate Change
353 Service (C3S). Extracted data (<https://cds.climate.copernicus.eu/cdsapp#!/dataset/reanalysis-era5-single-levels>) used here are hourly at a regular horizontal grid of $0.25^\circ \times 0.25^\circ$ in clear-sky
354 conditions: surface solar and thermal infrared, downward and net radiations. As explained on
355 the ERA5 website, clear-sky radiations are computed for the same atmospheric conditions of
356 temperature, humidity, ozone, trace gases and aerosol as the corresponding total-sky quantities
357 (clouds included), but assuming that the clouds are not there; ii) the Clouds and the Earth's
358 Radiant Energy System (CERES), containing SYN1deg (Hourly CERES and geostationary
359 (GEO) TOA fluxes, MODIS/VIIRS and GEO cloud properties, MODIS/VIIRS aerosols, and
360

361 Fu-Liou radiative transfer surface and in-atmospheric (profile) fluxes consistent with the
362 CERES observed TOA fluxes, as explained on <https://ceres.larc.nasa.gov/data/>). Surface fluxes
363 in SYN1deg are computed with cloud properties derived from MODIS and geostationary
364 satellites (GEO), where each geostationary satellite instrument is calibrated against MODIS
365 (Doelling et al. 2013; 2016) at 1°x1° horizontal resolution (<https://ceres.larc.nasa.gov/data/>).
366 Aerosol and atmospheric data were included as inputs to calculate the radiation flux.

367 We have compared the CERES and ERA5 data with the BSRN hourly-averaged data on
368 the 5 reference days (clear-sky conditions) for the Net, LWD, LWU, SWD and SWU SRs.
369 Figure 10 shows these variables for the 26 December 2021. The LWD and LWU values show
370 an overall consistency between ERA5 and CERES (of the order of ~10 W m⁻²), while a
371 systematic negative bias of ~20-40 W m⁻² is observed with respect to BSRN data. However,
372 the net longwave radiation, i.e. the difference LWD – LWU for each data set, is reduced to
373 around 5 W m⁻². The SWD and SWU signals from ERA5, CERES and BSRN show a similar
374 diurnal variation with differences less than 50 W m⁻². When considering the Net SR, some
375 obvious differences up to 50 W m⁻² can be seen between BSRN, ERA5 and CERES. Since the
376 net longwave radiation is within 10 W m⁻² for the three data sets, the source of this difference
377 therefore should come from either SWD or SWU radiation. We have calculated, for BSRN,
378 ERA5 and CERES data, the albedo defined as:

379
$$albedo = \frac{SWU}{SWD} \quad (10)$$

380 Figure 11 shows the diurnal evolution of the albedo on 26 December 2021 (clear-sky day).
381 The CERES and ERA5 albedos do not show any significant diurnal variation with quite
382 constant values of 0.74 and 0.83, respectively, whilst the observed BSRN albedo shows a clear
383 diurnal signal with a maximum of 0.85 from 10:00 to 14:00 UTC (from 18:00 to 22:00 LT) and
384 a minimum of 0.70 from 19:00 to 23:00 UTC (from 03:00 to 07:00 LT). The large diurnal signal
385 present in the observed albedo is likely the signature of the sastrugi effect that is obviously

386 absent in the ERA5 and CERES data sets. The BSRN SWU sensor has a circular footprint. For
 387 a sensor installed at a height h above the ground, 90% of the signal comes from an area at the
 388 surface closer than $3.1 h$ (Kassianov et al., 2014). Since at Dome-C the instrument is installed
 389 at a height of 2-3 m, the albedo is thus determined by the surface elements in the immediate
 390 vicinity (a few meters) of the sensor.

391 Sastrugi (Figure 12) are features formed by erosion of snow by wind. They are found in
 392 polar regions, and in snowy, wind-swept areas of temperate regions, such as frozen lakes or
 393 mountain ridges. Sastrugi are distinguished by upwind-facing points, resembling anvils, which
 394 move downwind as the surface erodes.

395 We have fitted the BSRN albedo averaged over the 5 reference days with the sum of 2 sine
 396 functions, imposing periods of 24 and 12 hours. Figure 13 shows the BSRN albedo averaged
 397 over the five clear-sky days, the fitted trigonometric function and the residuals between the
 398 averaged albedo and the fitted function. We can state that the sastrugi effect on the observed
 399 clear-sky albedo at Concordia is successfully fitted by 2 sine functions of 24h and 12h periods
 400 to within 0.003 mean absolute error, with a coefficient of determination R^2 equal to 0.993 and
 401 a root mean square error of 0.0004.

402 If we suppose that the sastrugi effect impacts mostly SWU rather than SWD, and the albedo
 403 calculated from BSRN observations is the “truth”, we can calculate a modified SWU*
 404 (including the sastrugi effect) for the ERA5 and CERES as:

$$405 \quad SWU(ERA5)^* = SWD(ERA5) \times albedo(BSRN) \quad (11)$$

$$406 \quad SWU(CERES)^* = SWD(CERES) \times albedo(BSRN) \quad (12)$$

407 Then we calculate the modified Net SR* (including the sastrugi effect) considering SWU* for
 408 ERA5 and CERES. As an example, we present Figure 14, similar to Figure 10, in which we
 409 added the albedo and the SWU* and Net SRs* (including the sastrugi effect) for CERES and
 410 ERA5 (solid lines). We observe that the Net SR* for ERA5 and CERES now coincides with

411 the BSRN Net SR to within 5 W m^{-2} , compared to differences up to 50 W m^{-2} found when the
412 sastrugi effect was not taken into account.

413 Moreover, we have considered all the BSRN observations in Decembers 2018, 2019, 2020
414 and 2021 to calculate the albedo (Figure 15), and we have superimposed the fitted trigonometric
415 function as described in Figure 13. The presence of clouds is well highlighted by observations
416 that depart from the fitted function whilst, during periods of clear-sky conditions, BSRN
417 albedos coincide well with the fitted function.

418 The study we have performed was extremely fruitful to evaluate the impact of the SLW
419 clouds on the SR. The methodology requires reference clear-sky SR values that can be
420 evaluated from: 1) models, 2) analyses and 3) observations. Our study has mainly shown that,
421 at the Concordia station, sastrugi were present and strongly impacted the net SR via the surface
422 albedo. This very local phenomenon cannot be taken into account by either the global-scale
423 analyses (ERA5 and CERES), or standard radiative transfer models (e.g. RRTMG). As a
424 consequence, the methodology we have developed based on field observations is likely the most
425 powerful tool to estimate the Net SR in Concordia. It has some drawbacks, as for instance some
426 biases for LWD and LWU between analyses and observations, but the LWD and LWU
427 difference used to calculate the Net SR dramatically lessens the bias.

428 *5.3. Modelling SLWC*

429 Previous studies have already underlined the difficulty to model the SLWC together with
430 its impact on surface radiations. Modelling SLWCs over Antarctica is challenging because 1)
431 operational observations are scarce since the majority of meteorological radiosondes are
432 released from ground stations located at the coast and very few of them are maintained all year
433 long, and satellite observations are limited to 60°S in geostationary orbit whilst, in polar orbit,
434 the number of available orbits does not exceed 15 per day, and 2) the model should provide a
435 partition function favouring liquid water at the expense of ice for temperatures between -36°C

436 and 0°C in order to calculate realistic SLW contents. Differences of 20 to 50 W m⁻² in the Net
437 SR were found in the Arpege model (Pailleux et al., 2015) between clouds made of ice or liquid
438 water during the summer 2018-2019 (Ricaud et al., 2020), differences that are very consistent
439 with the results obtained in the present study. Although SLWCs are less present over the
440 Antarctic Plateau than over the coastal region, their radiative impact is not negligible and should
441 be taken into account with great care in order to estimate the radiative budget of the Antarctic
442 continent in one hand, and, on the other hand, over the entire Earth.

443 *5.4. Errors*

444 Measurements of temperature, LWP, depolarization signal and SR are altered by random
445 and systematic errors that may affect the relationships we have obtained between LWP and
446 either temperature or SR anomalies. The temperature measured by HAMSTRAD below 1 km
447 has been evaluated against radiosonde coincident observations from 2009 to 2014 (Ricaud et
448 al., 2015) and the resulting bias is 0-2°C below 100 m and between -2 and 0°C between 100
449 and 1000 m. SLWCs are usually located around 400-600 m above the ground where the cold
450 bias can be estimated to be about -1.0°C. The one-sigma (1- σ) RMS temperature error over a
451 7-min integration time is 0.25°C in the PBL and 0.5°C in the free troposphere (Ricaud et al.,
452 2015). As a consequence, given the number of points used in the statistical analysis (>1000),
453 the random error on the weighted-average temperature is negligible (<0.02°C). The LWP
454 random and systematic errors are difficult to evaluate since there is no coincident external data
455 to compare with. Nevertheless, the 1- σ RMS error over a 7-min integration time can be
456 estimated to be 0.25 g m⁻² giving a random error on the weighted average LWP less than 0.08
457 g m⁻². Based on clear-sky observations, the positive bias can be estimated to be less than
458 0.4 g m⁻². Theoretically, SLW should not exist at temperatures less than -39°C although it has
459 been observed in recent laboratory measurements down to -42.55°C (Goy et al., 2018). Using
460 equation (8) with an LWP bias of 0.4 g m⁻² gives a temperature of -39.8°C (~0.8°C lower than

461 the theoretical limit of -39°C), so the biases estimated for temperature and LWP are very
462 consistent with theory.

463 The estimation of systematic and random errors on LIDAR backscattering and
464 depolarization signals and their impact on the attribution/selection of SLWC is not trivial. But
465 the most important point is to evaluate whether the observed cloud is constituted of purely liquid
466 or mixed-phase water. Even considering the backscatter intensity only, we could not exclude
467 that ice particles could have been present in the SLWC events investigated in 2018 (Ricaud et
468 al., 2020). Therefore, in the present analysis, although we made a great attention to diagnose
469 ice in the LIDAR cloud observations, we cannot totally exclude ice particles thus mixed-phase
470 parcels were actually present when we labelled the observed cloud as SLWCs.

471 The 4 instruments providing LWD, LWU, SWD and SWU SR follow the rules of
472 acquisition, quality check and quality control of the BSRN (Driemel et al., 2018). These data
473 are often considered as a reference against which products based on satellite observations and
474 radiative transfer models (such as e.g. CERES) are validated (Kratz et al., 2020). In polar
475 regions (Lanconelli et al., 2011), SWU and SWD SRs are expected to be affected by random
476 errors up to $\pm 20 \text{ W m}^{-2}$ while LWD SRs are expected to be affected by random errors not greater
477 than $\pm 10 \text{ W m}^{-2}$ (Ohmura et al., 1998). As a consequence, given the large number of
478 observations used per 5 W m^{-2} -wide bins (1000-3000), the random error on the weighted-
479 average SRs is negligible ($0.3\text{-}0.7 \text{ W m}^{-2}$) whatever the radiations considered, LW and SW.

480 Finally, apart from the instrument-related SR_{Ref} error, another source of error comes from
481 1) the geometry of observation and 2) the discontinuous SLWC layer. Firstly, LIDAR is almost
482 zenith pointing, HAMSTRAD makes a scan in the East direction (from 10° elevation to zenith),
483 whilst the BSRN radiometers detect the radiation in a 2π -steradians field of view (3D
484 configuration). That is to say, in our analysis, the whole sky contributes to the radiation whilst
485 only the cloud at zenith (1D configuration) and on the East direction (2D configuration) is

486 observed by the LIDAR and HAMSTRAD, respectively. Secondly, SLWCs cannot be
487 considered as uniform in the whole (see e.g. broken cloud fields in Figure 2).

488 5.5. *Other clouds*

489 Although the method we have developed to select the SLWCs has been validated using the
490 amount of LWP and, in another study, using space-borne observations (Ricaud et al., 2020), we
491 cannot rule out that, associated with the SLW droplets, are also ice particles, that is clouds are
492 constituted of a mixture of liquid and solid water. Generally, such clouds are a superposition of
493 a lower layer being made of liquid water and an upper layer being made of solid water (see Fig.
494 12.3 from Lamb and Verlinde, 2011). These mixed-layer clouds do not significantly modify the
495 relationship between temperature and LWP because 1) SLW observations from HAMSTRAD
496 are only sensitive to water in liquid phase and 2) temperature from HAMSTRAD is selected at
497 times and vertical heights where the LIDAR depolarization signal is very low (<5%). Although
498 we have verified that pure ice clouds were not selected by our method, we cannot differentiate
499 mixed-phase clouds from purely SLWCs. As a consequence, the presence of mixed-phase
500 clouds in addition to SLWCs may explain the negative part of the Net, LWD and LWU Δ SR
501 ($[-20;0] \text{ W m}^{-2}$) and the positive part of the SWD and SWU Δ SR ($[0;10] \text{ W m}^{-2}$) for low
502 values of LWP ($[0.8;1.6] \text{ g m}^{-2}$).

503 Furthermore, we already have noticed that SLWCs developed at the top of the PBL (Ricaud
504 et al., 2020) in the “entrainment zone” and maintained in the “capping inversion zone”,
505 following the terminology of Stull (1988), at a height ranging from 100 to 1000 m above ground
506 level. Nevertheless, during the local “night” at 00:00-06:00 LT, the PBL may collapse down to
507 a very low height ranging 20-50 m. In this configuration, it is hard to differentiate from LIDAR
508 observations between a SLWC and a fog episode, although the LIDAR can measure
509 depolarization (but not backscatter) down to approximately 10-30 m above the ground (Figure
510 S3 in Chen et al., 2017), so that we can distinguish liquid/frozen clouds very close to the ground.

511 Finally, we cannot rule out that, above the SLWCs that are actually observed by both
 512 LIDAR and HAMSTRAD, other clouds might be present, as e.g. cirrus clouds constituted of
 513 ice crystals. These mid-to-upper tropospheric clouds cannot be detected by HAMSTRAD (no
 514 sensitivity to ice crystals). In the presence of SLWCs either low in altitude or optically thick,
 515 the LIDAR backscatter signal is decreased in order to avoid saturation and the signal from upper
 516 layers is thus almost cancelled. These mid-to-high-altitude clouds are observed by the BSRN
 517 instruments and SR can be affected in this configuration. Based on the presence of cirrus clouds
 518 before or after the SLWCs (and sometimes during the SLWCs if optically thin), we can estimate
 519 that the number of days when SLWCs and cirrus clouds are simultaneously present to cover
 520 less than 10% of our period of interest.

521 *5.6. Potential radiative impact of SLWCs over Antarctica*

522 Based on 2007-2010 reanalyses, observations and climate models (Lenaerts et al., 2017),
 523 LWP over Antarctica is on average less than 10 g m^{-2} , with slightly larger values in summer
 524 than in winter by $2\text{-}5 \text{ g m}^{-2}$. Over Western Antarctica, LWPs are larger ($20\text{-}40 \text{ g m}^{-2}$) than over
 525 Eastern Antarctica ($0\text{-}10 \text{ g m}^{-2}$). As a consequence, LWPs observed at Concordia are consistent
 526 with values observed over the Eastern Plateau, with a factor 2-4 smaller than those observed
 527 over the Western continent. Based on our results and on the observed cloud fraction (η_{CF}) of
 528 SLWCs over Antarctica for different seasons (Listowski et al., 2019), we have estimated the
 529 potential radiative impact of SLWCs at the scale of the Antarctic continent ($Net \Delta SR_{global}^{max}$)
 530 from the maximum of $Net \Delta SR$ ($Net \Delta SR^{max} = 50 \text{ W m}^{-2}$) computed in our study:

$$531 \quad Net \Delta SR_{global}^{max} = \eta_{CF} \times Net \Delta SR^{max} \quad (13)$$

532 In summer, η_{CF} is varying from 5% in Eastern Antarctica to 40% in Western Antarctica whilst,
 533 in winter, it is varying from 0% in Eastern Antarctica to 20% in Western Antarctica (Listowski
 534 et al., 2019). In December, if we consider η_{CF} for SLW-containing cloud (that is to say both
 535 mixed-phase cloud and unglaciated SLW cloud consistent with our study), we find for a lower-

536 level altitude cut-off of 0, 500 and 1000 m (Figure B1 in Listowski et al., 2019), a potential
537 radiative impact $Net \Delta SR_{global}^{max}$ over Antarctica of 9, 7 and 5 $W m^{-2}$, respectively. We now
538 separate the Eastern elevated Antarctic Plateau from the Western Antarctica (Figure 5 in
539 Listowski et al., 2019) for the 4 seasons. Over Eastern Antarctica, we find that $Net \Delta SR_{global}^{max} =$
540 0.5-5.0 $W m^{-2}$ in December-January-February (DJF) and 0-2.5 $W m^{-2}$ for the remaining
541 seasons. Over Western Antarctica, the potential radiative impact is much more intense because
542 of higher temperatures and lower elevations compared to the Eastern Antarctic Plateau:
543 $Net \Delta SR_{global}^{max} = 12.5-30.0 W m^{-2}$ in DJF (30 $W m^{-2}$ over the Antarctica Peninsula); 7.5-20.0
544 $W m^{-2}$ in March-April-May; 2.5-10.0 $W m^{-2}$ in June-July-August; and 5.0-12.5 $W m^{-2}$ in
545 September-October-November.

546

547 **6. Conclusions**

548 Combining the observations of temperature, water vapour and liquid water path from a
549 ground-based microwave radiometer, backscattering and depolarization from a ground-based
550 LIDAR and surface radiations at long and short wavelengths, our analysis has been able to
551 evaluate the presence of supercooled liquid water clouds over the Dome C station in summer.
552 Focusing on the month of December in 2018-2021, we established that in SLWCs temperature
553 logarithmically increases from $-36.0^{\circ}C$ to $-16.0^{\circ}C$ when LWP increases from 1.0 to 14.0 $g m^{-2}$.
554 We have also evaluated that SLWCs positively affect the net SR, which logarithmically
555 increases from 0.0 to 50.0 $W m^{-2}$ when LWP increases from 1.7 to 3.0 $g m^{-2}$. Our study clearly
556 shows that: 1) SLWCs have a positive impact on LWD and LWU, with ΔSR increasing from 0
557 to 100 $W m^{-2}$ and from 0 to 40 $W m^{-2}$ for LWP ranging from 1.0 to 4.0 and from 1.6 to 2.5 $g m^{-2}$,
558 respectively, and 2) SLWCs have a clear negative impact on SWD and SWU, with ΔSR
559 decreasing from 0 to $-140 W m^{-2}$ and from 0 to $-75 W m^{-2}$ with LWP ranging from 1.2 to 3.8
560 and from 1.2 to 3.2 $g m^{-2}$, respectively.

561 Our study has ~~mainly~~ shown that, at the Concordia station, sastrugi were present and
562 strongly impacted the net SR via the surface albedo. This very local phenomenon cannot be
563 taken into account by either the global-scale analyses (ERA5 and CERES), or standard radiative
564 transfer models. As a consequence, the methodology we have developed based on field
565 observations is likely the most powerful tool to estimate the Net SR in Concordia. It has some
566 drawbacks, as for instance some biases for LWD and LWU between analyses and observations,
567 but the LWD – LWU difference that is used to calculate the Net SR dramatically lessens the
568 bias.

569 Finally, extrapolating the radiative impact of the SLWCs from the Dome C station to the
570 Antarctic continent shows that SLWCs have a great potential radiative impact all over
571 Antarctica whatever the season considered, up to 5.0 W m^{-2} over the Eastern Antarctic Plateau
572 and up to 30 W m^{-2} over the Antarctic Peninsula in summer season. This stresses the importance
573 of accurately modelling SLWCs when calculating the Earth energy budget to adequately
574 forecast the Earth climate evolution, especially since the climate is rapidly changing in
575 Antarctica, as illustrated by the surface temperature record of -12°C recently observed in March
576 2022 at the Concordia station and largely publicized worldwide (see e.g.
577 [https://www.9news.com.au/world/antarctica-heatwave-extreme-warm-weather-recorded-
578 concordia-research-station/3364dd91-2051-4df5-8cfc-5f2819058604](https://www.9news.com.au/world/antarctica-heatwave-extreme-warm-weather-recorded-concordia-research-station/3364dd91-2051-4df5-8cfc-5f2819058604)).

579

580 **Data availability**

581 HAMSTRAD data are available at <http://www.cnrm.meteo.fr/spip.php?article961&lang=en>
582 (last access: 3 May 2022). The tropospheric depolarization LIDAR data are reachable at
583 <http://lidarmax.altervista.org/lidar/home.php> (last access: 3 May 2022). Radiosondes are
584 available at <http://www.climantartide.it> (last access: 3 May 2022). BSRN data can be obtained
585 from the ftp server (<https://bsrn.awi.de/data/data-retrieval-via-ftp/>) (last access: 3 May 2022).

586

587 **Author contribution**

588 PR, MDG, and AL provided the observational data. PR developed the methodology. All the
589 co-authors participated in the data analysis and in the data interpretation. PR prepared the
590 manuscript with contributions from all co-authors.

591

592 **Competing interests**

593 The authors declare that they have no conflict of interest.

594

595 **Acknowledgments**

596 The present research project Water Budget over Dome C (H₂O-DC) has been approved by
597 the Year of Polar Prediction (YOPP) international committee. The HAMSTRAD programme
598 (910) was supported by the French Polar Institute, Institut polaire français Paul-Emile Victor
599 (IPEV), the Institut National des Sciences de l'Univers (INSU)/Centre National de la Recherche
600 Scientifique (CNRS), Météo-France and the Centre National d'Etudes Spatiales (CNES). The
601 permanently manned Concordia station is jointly operated by IPEV and the Italian Programma
602 Nazionale Ricerche in Antartide (PNRA). The tropospheric LIDAR operates at Dome C from
603 2008 within the framework of several Italian national (PNRA) projects. We would like to thank
604 all the winterover personnel who worked at Dome C on the different projects: HAMSTRAD,
605 aerosol LIDAR and BSRN. We would like to thank the two anonymous reviewers for their
606 beneficial comments.

769

770 **Table 2.** Gaussian functions fitted to the $N(x)$ function for $x = \theta$ ($^{\circ}\text{C}$) or ΔSR (W m^{-2}). Units
 771 of a_1 , a_2 , a_3 , and c are in count number for θ and ΔSR ; units of μ_1 , μ_2 , μ_3 , σ_1 , σ_2 , and σ_3 are
 772 in $^{\circ}\text{C}$ for θ and in W m^{-2} for ΔSR .

x	a_1	μ_1	σ_1	a_2	μ_2	σ_2	a_3	μ_3	σ_3	c
θ	$15.0 \cdot 10^3$	-31.5	1.45	$5.0 \cdot 10^3$	-28.0	1.65	$0.5 \cdot 10^3$	-19.0	2.5	$-9.1 \cdot 10^{-6}$
Net ΔSR	2106.5	0.02	19.2	941.4	29.8	22.0	-	-	-	19.5
LWD ΔSR	1010.8	80.1	21.9	1565.6	10.0	23.9	-	-	-	18.4
LWU ΔSR	1476.4	-10.0	14.9	1834.7	25.0	16.2	-	-	-	185.4
SWD ΔSR	1317.2	-5.0	15.8	717.4	-80.0	64.7	-	-	-	9.1
SWU ΔSR	1928.8	-5.0	19.2	1163.4	-59.9	17.6	-	-	-	9.1

773

774

775 **Table 3.** Coefficients of the relations $f(LWP) = a + b \ln(LWP)$ for the temperature θ or
776 surface radiation anomalies ΔSR . Units of θ and ΔSR , as well as of their corresponding “ a ”
777 values are in $^{\circ}\text{C}$ and W m^{-2} , respectively; units of b are in $^{\circ}\text{C g}^{-1} \text{m}^2$ for θ and in W / g for ΔSR ;
778 units of LWP are in g m^{-2} . The last column shows the range of LWP values for which the
779 relation is valid (in black), and in red (blue) the sub-range in which a positive (negative) impact
780 is observed on ΔSR . Note that $a \pm \delta a$ corresponds to the range of a values where the
781 relationship is valid.

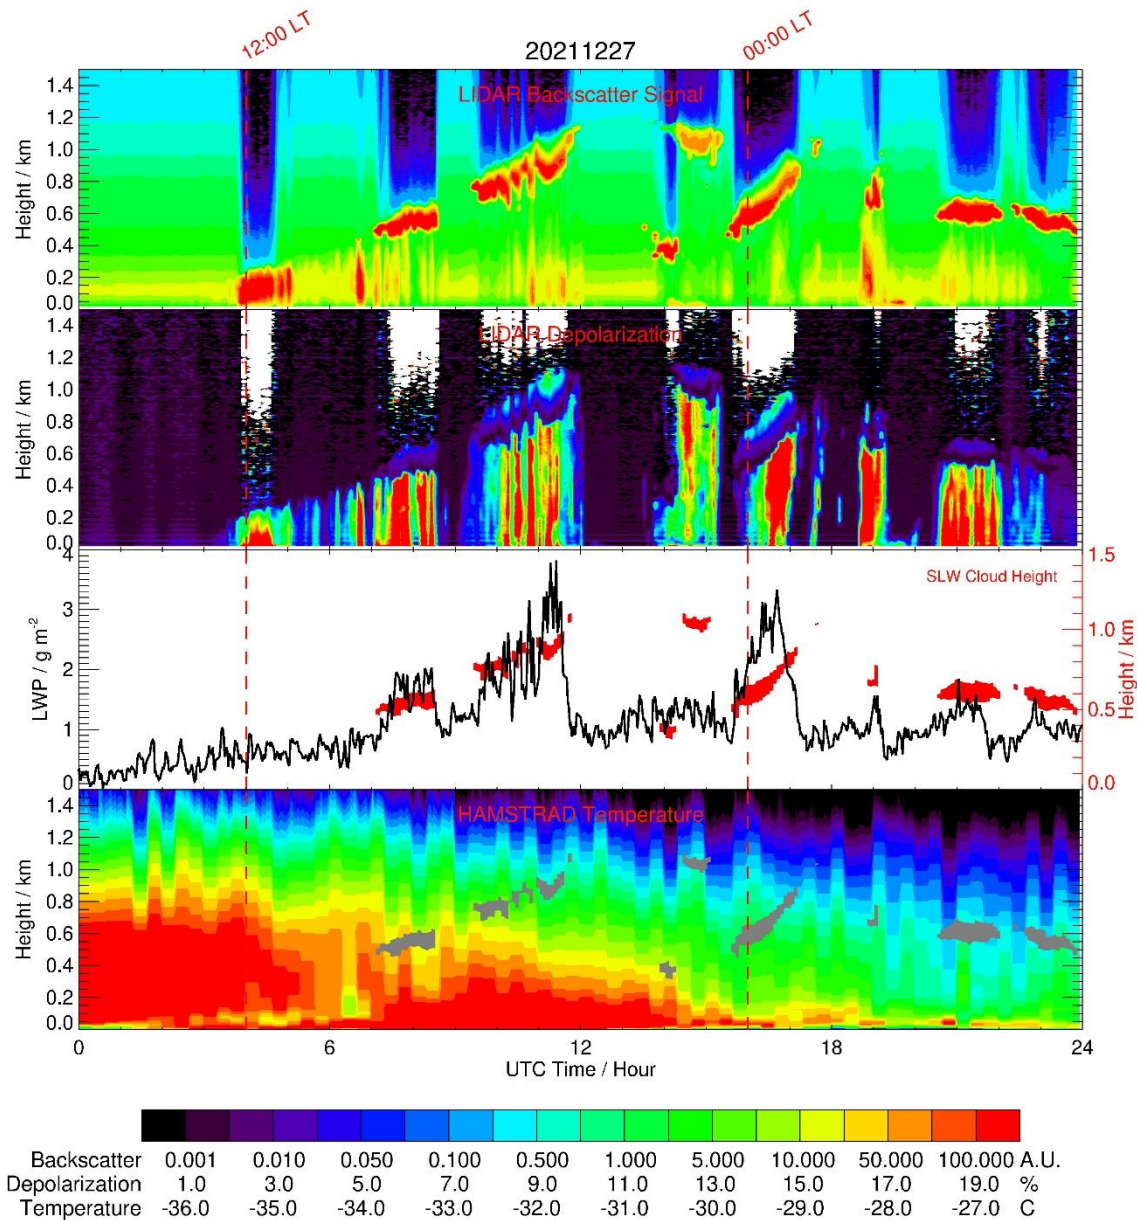

$f(LWP)$	$a \pm \delta a$	b	Valid range for θ or ΔSR	Valid range for LWP
θ	-33.8 ± 1.5	6.5	$[-36; -16]$	$[1.0; 14.0]$
Net ΔSR	-50.0 ± 10.0	90.0	$[-15; 50]$	$[1.5; 3.0]$ / $[1.7; 3.0]$
LWD ΔSR	5.0 ± 15.0	65.0	$[-10; 100]$	$[0.8; 4.0]$ / $[1.0; 4.0]$
LWU ΔSR	-45.0 ± 30.0	90.0	$[-20; 40]$	$[1.3; 2.5]$ / $[1.6; 2.5]$
SWD ΔSR	30.0 ± 30.0	-130.0	$[-140; 10]$	$[1.1; 3.8]$ / $[1.2; 3.8]$
SWU ΔSR	15.0 ± 15.0	-75.0	$[-75; 10]$	$[1.1; 3.2]$ / $[1.2; 3.2]$

788 **Figure 1:** (From top to bottom): Time evolution (UTC, hour) of the Lidar Backscattering
 789 Signal, the Lidar Depolarization Signal, the HAMSTRAD LWP and the HAMSTRAD
 790 temperature profile measured on 27 December 2021. The time evolution of the SLW cloud (as
 791 diagnosed by a backscattering signal > 60 A.U. and a depolarization signal $< 5\%$) is highlighted
 792 by the red and grey areas in the third and the forth panel from the top, respectively. The height
 793 above the ground is shown on the third panel from the top with the y-axis on the right. The
 794 00:00 and 12:00 local times (LT) are highlighted by 2 vertical dashed lines.

795

796 **Figure 2:** (Top) Time evolution (UTC, hour) of the SLWC (red areas) on 27 December 2021.

797 (Bottom, from left to right) Snapshots from the HALO-CAM video camera taken on: 01:00 (no

798 SLWC), 07:19 (SLWC), 09:00 (no SLWC), 10:14 (SLWC), 13:00 (no SLWC), 16:03 (SLWC),

799 18:01 (no SLWC) and 20:53 UTC (SLWC). The 00:00 and 12:00 local times (LT) are

800 highlighted by 2 vertical dashed lines.

801

802

803

804 **Figure 3:** Time evolution (UTC, hour) of the clear-sky surface radiations (SR, W m^{-2}) observed
 805 by the BSRN instruments on 2 December 2018 (red), 19 December 2018 (orange), 3 December
 806 2021 (green), 17 December 2021 (blue) and 26 December 2021 (black): (from top to bottom)
 807 Net SR, Longwave Downward SR (LWD SR), Longwave Upward SR (LWU SR), Shortwave
 808 Downward SR (SWD SR) and Shortwave Upward SR (SWU SR). The 00:00 and 12:00 local
 809 times (LT) are highlighted by 2 vertical dashed lines.

810

811 **Figure 4:** Time evolution (UTC, hour) of the clear-sky surface radiation variability ($\delta\text{SR}_{\text{Ref}}$, W
 812 m^{-2}), namely the clear-sky surface radiations observed by the BSRN instruments on 2 December
 813 2018 (red), 19 December 2018 (orange), 3 December 2021 (green), 17 December 2021 (blue)
 814 and 26 December 2021 (black) minus the corresponding values averaged over the 5 cloud-free
 815 days: (from top to bottom) Net SR, Longwave Downward SR (LWD SR), Longwave Upward

816 SR (LWU SR), Shortwave Downward SR (SWD SR) and Shortwave Upward SR (SWU SR).

817 The 00:00 and 12:00 local times (LT) are highlighted by 2 vertical dashed lines.

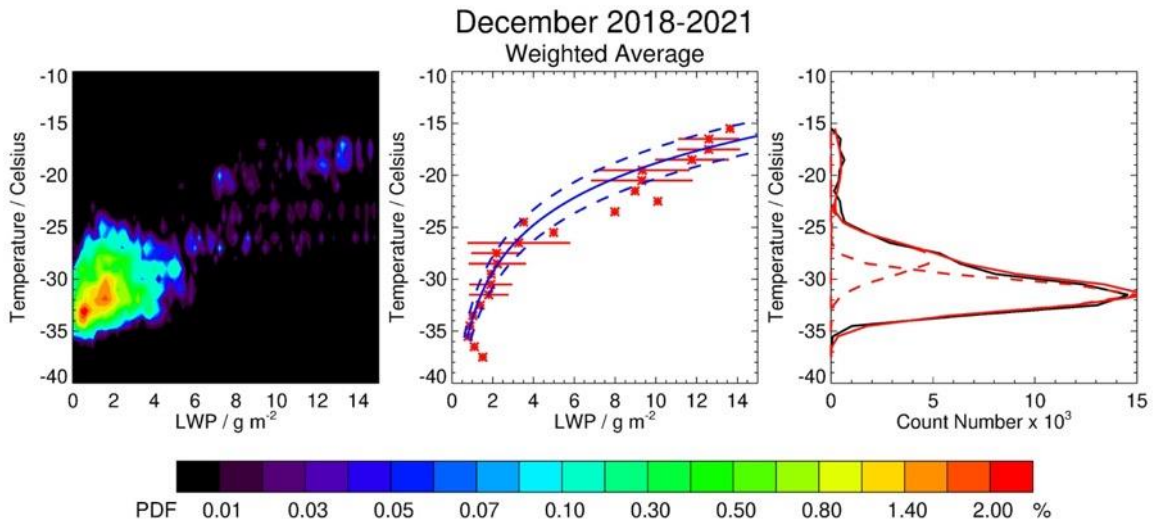

818

819

820

821 **Figure 5:** Time evolution (UTC, hour) of the Surface Radiation Anomaly (ΔSR), difference
 822 between the SR ($W m^{-2}$) measured on 27 December 2021 and the reference clear-sky (SR_{Ref})
 823 SR ($W m^{-2}$) measured on 26 December 2021: (from top to bottom) Net (Net ΔSR), longwave
 824 downward (LWD ΔSR), longwave upward (LWU ΔSR), shortwave downward (SWD ΔSR) and
 825 shortwave upward (SWU ΔSR). The time evolution of the SLW cloud is highlighted by a red
 826 area in the uppermost panel, with the height on the y-axis shown on the right. The 00:00 and
 827 12:00 local times (LT) are highlighted by 2 vertical blue dashed lines.

828

829 **Figure 6:** (Left) Probability Density (%) of the Temperature ($^{\circ}\text{C}$) as a function of Liquid Water
 830 Path (LWP, g m^{-2}) contained in the Supercooled Liquid Water clouds (SLWCs) above Dome C
 831 in December 2018-2021. The Probability Density is defined in the text. (Centre) Weighted-
 832 average LWP vs. temperature (red asterisks) with a fitted logarithmic function (blue solid)
 833 encompassing the significant points (2 dashed blue lines). Horizontal bars represent 1-sigma
 834 variability in LWP per 1°C -wide bin over significant points. (Right) Temperature as a function
 835 of count number per 1°C -wide bin (black solid line) with 3 fitted Gaussian functions (red dashed
 836 curves). The sum of the 3 Gaussian functions is represented by a red solid line.

837

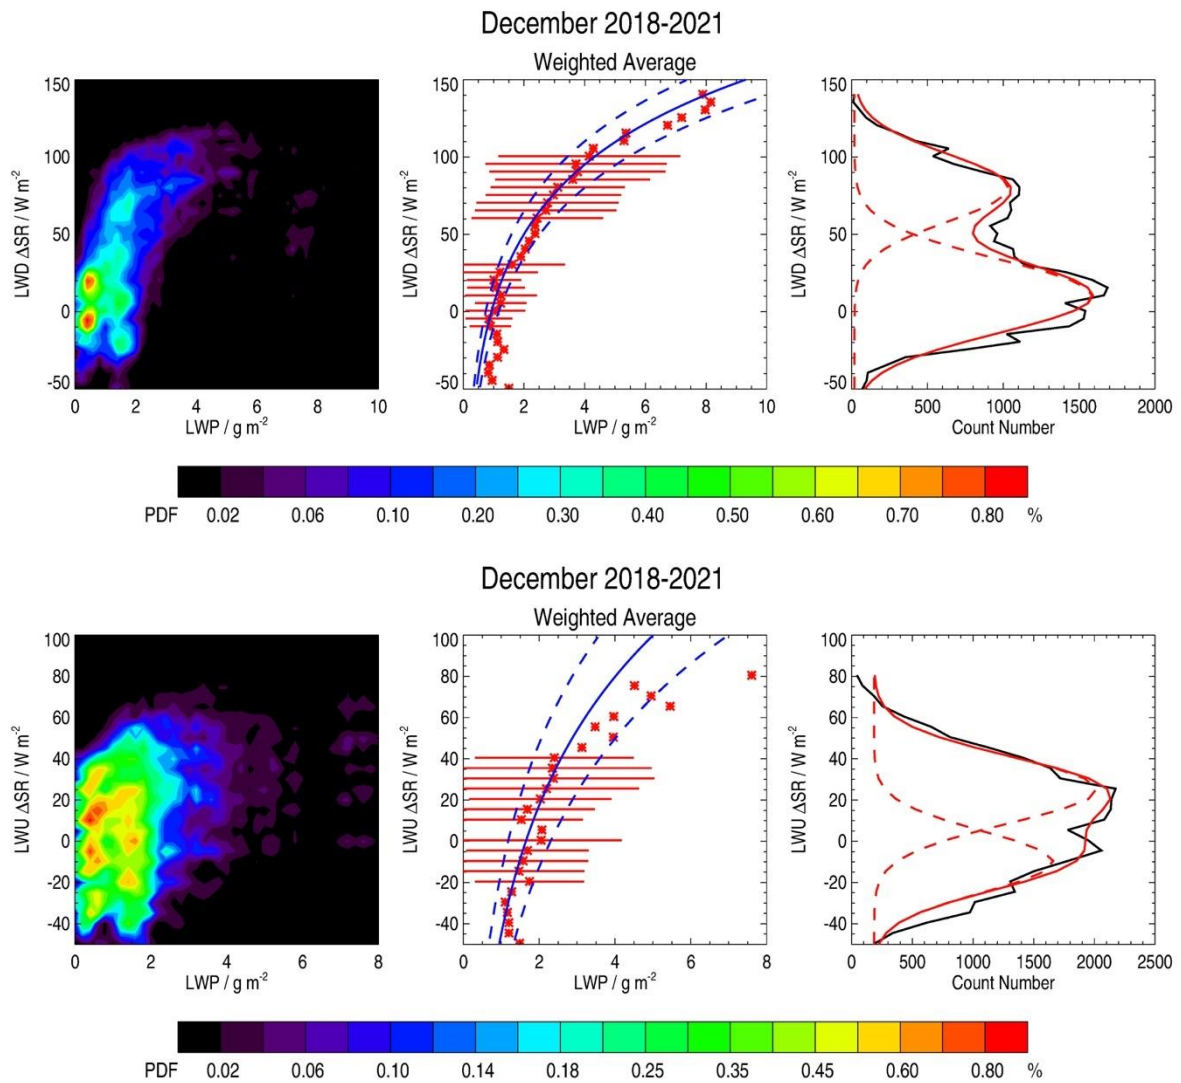

838

839

840 **Figure 7:** (Left) Probability Density (%) of the Net Surface Radiation Anomaly (Net ΔSR , W
 841 m^{-2}) as a function of Liquid Water Path (LWP, $g m^{-2}$) contained in the Supercooled Liquid
 842 Water clouds (SLWCs) above Dome C in December 2018-2021. The Probability Density is
 843 defined in the text. (Centre) Weighted-average LWP vs. Net ΔSR (red asterisks) with a fitted
 844 logarithmic function (blue solid) encompassing the significant points (2 dashed blue lines).
 845 Horizontal bars represent 1-sigma variability in LWP per $5 W m^{-2}$ -wide bin over significant
 846 points. (Right) Net ΔSR as a function of count number per $5 W m^{-2}$ -wide bin (black solid line)
 847 with 2 fitted Gaussian functions (red dashed curves). The sum of the 2 Gaussian functions is
 848 represented by a red solid line.

849

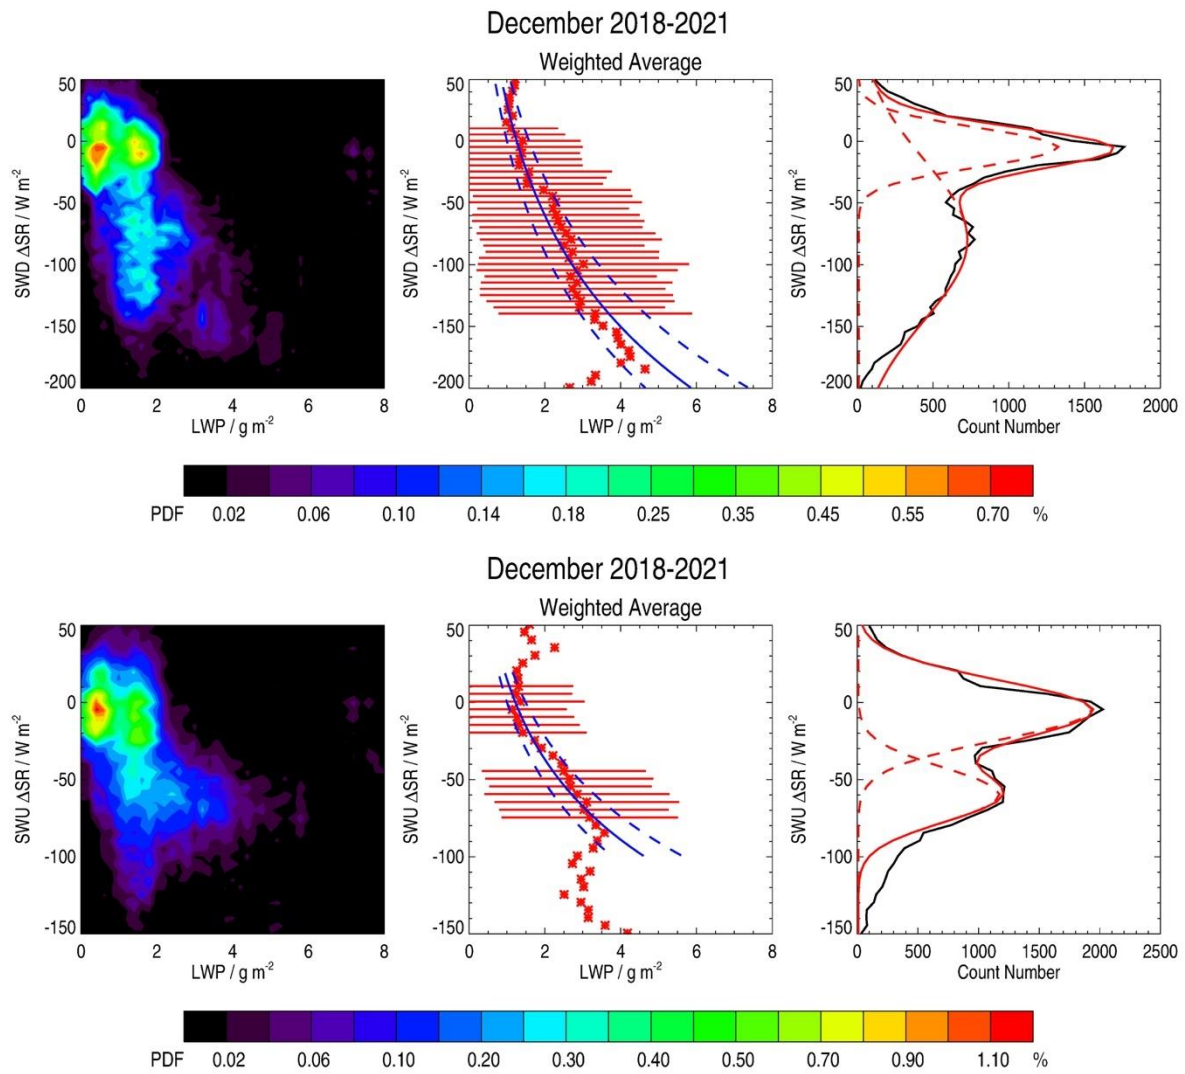

850

851 **Figure 8:** As in Figure 7 but for the Longwave Downward (top) and Upward (bottom) Surface
 852 Radiation Anomaly (LWD and LWU ΔSR , respectively).

853

854

855

856 **Figure 9:** As in Figure 7 but for the Shortwave Downward (top) and Upward (bottom) Surface
 857 Radiation Anomaly (SWD and SWU ΔSR , respectively).

858

859

860

861 **Figure 10:** Hourly time evolution (UTC, hour) of the clear-sky surface radiations (SR, W m^{-2})
 862 observed by the BSRN instruments (blue asterisks), the CERES (green asterisks) and the ERA5
 863 (red asterisks) data sets on 26 December 2021: (from top to bottom) Net SR, Longwave
 864 Downward SR (LWD SR), Longwave Upward SR (LWU SR), Shortwave Downward SR
 865 (SWD SR) and Shortwave Upward SR (SWU SR). The 00:00 and 12:00 local times (LT) are
 866 highlighted by 2 vertical dashed lines.

867

868

869 **Figure 11:** Time evolution (UTC, hour) of the surface albedo observed by the BSRN
 870 instruments (blue), the CERES (green) and the ERA5 (red) data sets on 26 December 2021.
 871 The 00:00 and 12:00 local times (LT) are highlighted by 2 vertical dashed lines.

872

873

874

875 **Figure 12:** Image of the sastrugi on the ice surface (Wikimedia Commons).

876

877 **Figure 13:** (Top) Hourly time evolution (UTC, hour) of the mean surface albedo observed by
 878 the BSRN instruments (blue star) associated with the 5 clear-sky periods under consideration
 879 in our analysis together with the associated standard deviation (vertical bar) together with the
 880 fitted trigonometric function based on 2 sine functions (red). (Center) The 2 sine functions
 881 fitting the hourly time evolution of the BSRN mean surface albedo. (Bottom) Hourly time
 882 evolution (UTC, hour) of the albedo residuals (BSRN-fit) and associated Root Mean Square
 883 Error (RMSE), Coefficient of determination (R^2), and Mean Absolute Error (MAE).

884

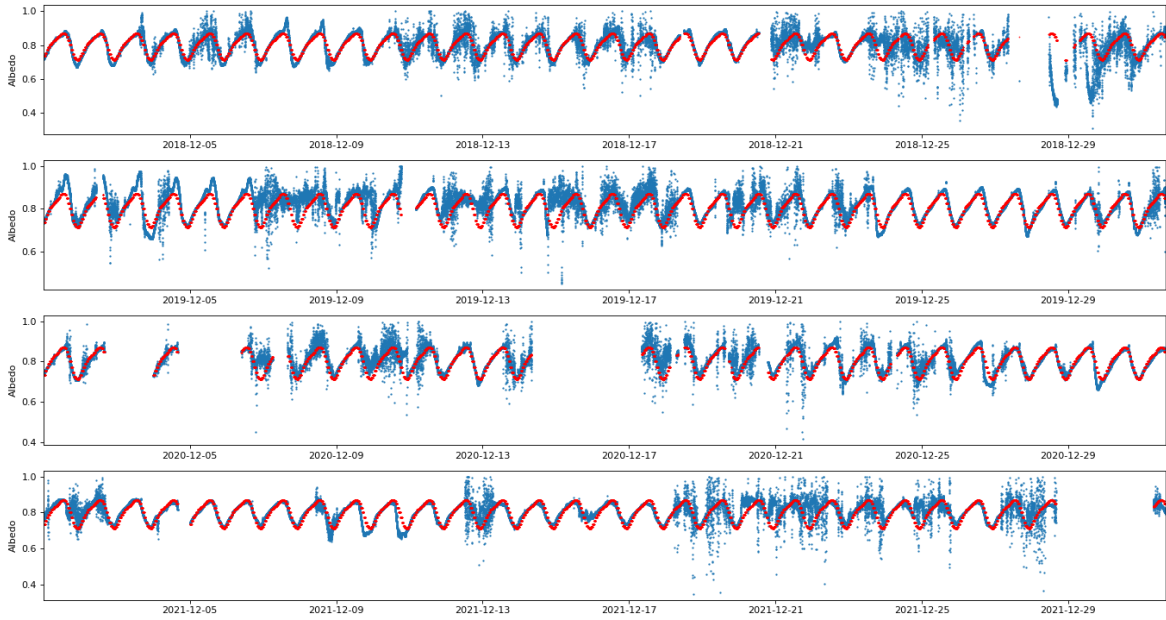

885

886 **Figure 14:** Same as Figure 11 with the albedo inserted in the lowermost panel. Net SR, SWU

887 SR, and albedo including the sastrugi effect for ERA5 (red solid line) and CERES (green solid

888 line) have also been added in the Figures.

889

890

891 **Figure 15:** Hourly time evolution (UTC, hour) of the surface albedo observed by the BSRN
892 instruments (blue), and using the fit function based on 2 sine functions (red) for the whole
893 BSRN data set covering the month of December in 2018, 2019, 2020 and 2021.
