22

23 **Abstract**

24 Clouds affect the Earth climate with an impact that depends on the cloud nature (solid/  
25 liquid water). Although the Antarctic climate is changing rapidly, cloud observations are sparse  
26 over Antarctica due to few ground stations and satellite observations. The Concordia station is  
27 located on the East Antarctic Plateau (75°S, 123°E, 3233 m above mean sea level), one of the  
28 driest and coldest places on Earth. We used observations of clouds, temperature, liquid water  
29 and surface irradiance performed at Concordia during 4 austral summers (December 2018-  
30 2021) to analyse the link between liquid water and temperature and its impact on surface  
31 irradiance in the presence of supercooled liquid water (liquid water for temperature less than  
32 0°C) clouds (SLWCs). Our analysis shows that, within SLWCs, temperature logarithmically  
33 increases from -36.0°C to -16.0°C when liquid water path increases from 1.0 to 14.0 g m<sup>-2</sup>. The  
34 SLWC radiative forcing is positive and logarithmically increases from 0.0 to 70.0 W m<sup>-2</sup> when  
35 liquid water path increases from 1.2 to 3.5 g m<sup>-2</sup>. This is mainly due to the downward longwave  
36 component that logarithmically increases from 0 to 90 W m<sup>-2</sup> when liquid water path increases  
37 from 1.0 to 3.5 g m<sup>-2</sup>. The attenuation of shortwave incoming irradiance (that can reach more  
38 than 100 W m<sup>-2</sup>) is almost compensated for by the upward shortwave irradiance because of high  
39 values of surface albedo. Based on our study, we can extrapolate that, over the Antarctic  
40 continent, SLWCs have a maximum radiative forcing rather weak over the Eastern Antarctic  
41 Plateau (0 to 7 W m<sup>-2</sup>) but 3 to 5 times larger over Western Antarctica (0 to 40 W m<sup>-2</sup>),  
42 maximizing in summer and over the Antarctic Peninsula.

43

## 44 **1. Introduction**

45 Antarctic clouds play an important role in the climate system by influencing the Earth's  
46 radiation balance, both directly at high southern latitudes and, indirectly, at the global level  
47 through complex teleconnections (Lubin et al., 1998). However, in Antarctica, ground stations  
48 are mainly located on the coast and yearlong observations of clouds and associated  
49 meteorological parameters are scarce. Meteorological analyses and satellite observations of  
50 clouds can nevertheless give some information on cloud properties suggesting that clouds vary  
51 geographically, with a fractional cloud cover ranging from about 50 to 60% around the South  
52 Pole to 80-90% near the coast (Bromwich et al., 2012; Listowski et al., 2019). In situ aircraft  
53 measurements performed mainly over the Western Antarctic Peninsula (Grosvenor et al., 2012;  
54 Lachlan-Cope et al., 2016) and nearby coastal areas (O'Shea et al., 2017) provided new insights  
55 to polar cloud modelling and highlighted sea-ice production of Cloud-Condensation Nuclei  
56 (CCN) and Ice Nucleating Particles (INPs) (see e.g. Legrand et al., 2016). Mixed-phase clouds  
57 (made of solid and liquid water) are preferably observed near the coast (Listowski et al., 2019)  
58 with larger ice crystals and water droplets (Lachlan-Cope, 2010; Lachlan-Cope et al., 2016;  
59 Grosvenor et al., 2012; O'Shea et al., 2017; Grazioli et al., 2017). Based on the raDAR/liDAR-  
60 MASK (DARDAR) spaceborne products (Listowski et al., 2019), it has been found that clouds  
61 are mainly constituted of ice above the continent. The abundance of Supercooled Liquid Water  
62 (SLW, the water staying in liquid phase below 0°C) clouds depends on temperature and  
63 liquid/ice fraction. It decreases sharply poleward, and is two to three times lower over the  
64 Eastern Antarctic Plateau than over the Western Antarctic. Furthermore, the nature and optical  
65 properties of the clouds depend on the type and concentration of CCN and INPs. Bromwich et  
66 al. (2012) mention in their review paper that CCN and INPs are of various nature and large  
67 uncertainties exist relative to their origin and abundance over Antarctica. An important point  
68 remains the inability of both research and operational weather prediction models to accurately

69 represent the clouds (especially SLW clouds, SLWCs) in Antarctica causing biases of several  
70 tens  $W m^{-2}$  on net surface irradiance (Listowski and Lachlan-Cope, 2017; King et al., 2006,  
71 2015; Bromwich et al., 2013) over and beyond the Antarctic (Lawson and Gettelman, 2014;  
72 Young et al. 2019). From year-long LIDAR observations of mixed-phase clouds at South Pole  
73 (Lawson and Gettelman, 2014), SLWCs were shown to occur more frequently than in earlier  
74 aircraft observations or weather model simulations, leading to biases in the surface radiation  
75 budget estimates.

76 Liquid water in clouds may occur in supercooled form due to a relative lack of ice nuclei  
77 for temperature greater than  $-39^{\circ}C$  and less than  $0^{\circ}C$ . Very little SLW is then expected because  
78 the ice crystals that form in this temperature range will grow at the expense of liquid droplets  
79 (called the “Wegener-Bergeron-Findeisen” process; Wegener, 1911; Bergeron, 1928;  
80 Findeisen, 1938; Storelvmo and Tan, 2015). Nevertheless, SLW is often observed at negative  
81 temperatures higher than  $-20^{\circ}C$  at all latitudes being a danger to aircraft since icing on the wings  
82 and airframe can occur, reducing lift, and increasing drag and weight. As temperature decreases  
83 to  $-36^{\circ}C$ , SLW dramatically lessens, so it is highly difficult 1) to observe SLWCs and 2) to  
84 quantify the amount of liquid water present in SLWCs. But during the Year Of Polar Prediction  
85 (YOPP) international campaign, recent observations performed at the Dome C station in  
86 Antarctica of two case studies in December 2018 have revealed SLWCs with temperature  
87 between  $-20^{\circ}C$  and  $-30^{\circ}C$  and Liquid Water Path (LWP, the liquid water content integrated  
88 along the vertical) between 2 to  $20 g m^{-2}$ , as well as a considerable impact on the net surface  
89 irradiance that exceeded the simulated values by 20 to  $50 W m^{-2}$  (Ricaud et al., 2020).

90 The Dome C (Concordia) station, jointly operated by French and Italian institutions in the  
91 Eastern Antarctic Plateau ( $75^{\circ}06'S$ ,  $123^{\circ}21'E$ , 3233 m above mean sea level, amsl), is one of  
92 the driest and coldest places on Earth with surface temperatures ranging from about  $-20^{\circ}C$  in  
93 summer to  $-70^{\circ}C$  in winter. There are four main instruments relevant to this study that have

94 been routinely running for about 10 years: 1) The H<sub>2</sub>O Antarctica Microwave Stratospheric and  
 95 Tropospheric Radiometer (HAMSTRAD, Ricaud et al., 2010a) to obtain vertical profiles of  
 96 temperature and water vapour, as well as the LWP. 2) The tropospheric depolarization LIDAR  
 97 (Tomasi et al., 2015) to obtain vertical profiles of backscatter and depolarization to be used for  
 98 the detection of SLWCs. 3) An Automated Weather Station (AWS) to provide screen-level air  
 99 temperature. And 4) the Baseline Surface Radiation Network (BSRN) station to measure  
 100 downward and upward longwave (4 to 50 μm) and shortwave (0.3 to 3 μm) surface irradiances  
 101 ( $F$ ) from which the net surface irradiance ( $F_{Net}$ ), calculated as the difference between the  
 102 downward and upward components, can be computed (Driemel et al., 2018) as:

$$103 \quad F_{Net} = (F_{LW}^{Down} - F_{LW}^{Up}) + (F_{SW}^{Down} - F_{SW}^{Up}) \quad (1)$$

104 where  $F_{LW}^{Down}$ ,  $F_{LW}^{Up}$ ,  $F_{SW}^{Down}$ , and  $F_{SW}^{Up}$  represent the downward longwave, upward longwave,  
 105 downward shortwave and upward shortwave surface irradiances, respectively.

106 At a given time, the impact of a cloud on the surface irradiance is estimated from the  
 107 difference between the net irradiance, in cloudy ( $F_{Net,cl}$ ) and cloud-free ( $FCF_{Net}$ ) conditions  
 108 to provide the so-called “cloud radiative forcing”  $\Delta F_{Net}$  (e.g., Stapf et al., 2020):

$$109 \quad \Delta F_{Net} = F_{Net,cl} - FCF_{Net} \quad (2)$$

110 A similar equation can be written for each of the four irradiances that appear in the right-hand  
 111 side of equation (1). The aim of the present study is double. Using observations performed at  
 112 Concordia, we intend to quantify the link between 1) temperature in the SLWCs and LWP and  
 113 2) SLWC radiative forcing and LWP.

114 The article is structured as follows. Section 2 presents the instruments during the period of  
 115 study. In section 3, we detail the methodology employed to detect the SLWCs and calculate  
 116 their cloud radiative forcing, and we present the statistical method to emphasize the relationship  
 117 between in-cloud temperature and LWP on the one hand, and cloud radiative forcing and LWP

118 on the other hand. The results are highlighted in section 4 and discussed in section 5, before  
119 concluding in section 6.

120

## 121 **2. Instruments**

122 We have used the observations from 4 instruments held at the Dome C station, namely the  
123 LIDAR instrument to classify the cloud as SLWC, the HAMSTRAD microwave radiometer to  
124 obtain LWP and vertical profile of temperature, the AWS to obtain screen-level air temperature  
125 and the BSRN network to measure the surface irradiances ( $F_{LW}^{Down}$ ,  $F_{LW}^{Up}$ ,  $F_{SW}^{Down}$ , and  $F_{SW}^{Up}$ ) to  
126 obtain  $F_{Net}$ .

### 127 *2.1. LIDAR*

128 The tropospheric depolarization LIDAR (532 nm) has been operating at Dome C since 2008  
129 (see [http://lidarmax.altervista.org/englidar/\\_Antarctic%20LIDAR.php](http://lidarmax.altervista.org/englidar/_Antarctic%20LIDAR.php)). The LIDAR provides  
130 5-min tropospheric profiles of clouds characteristics continuously, from 20 to 7000 m above  
131 ground level (agl), with a resolution of 7.5 m. For the present study, the most relevant parameter  
132 is the LIDAR depolarization ratio (Mishchenko et al., 2000) that is a robust indicator of non-  
133 spherical shape for randomly oriented cloud particles. A depolarization ratio below 10% is  
134 characteristic of SLWC, while higher values are produced by ice particles. The possible  
135 ambiguity between SLW droplets and oriented ice plates is avoided at Dome C by operating  
136 the LIDAR 4° off-zenith (Hogan and Illingworth, 2003).

### 137 *2.2. HAMSTRAD*

138 HAMSTRAD is a microwave radiometer that profiles water vapour, liquid water and  
139 tropospheric temperature above Dome C. Measuring at both 60 GHz (oxygen molecule line  
140 (O<sub>2</sub>) to deduce the temperature) and 183 GHz (H<sub>2</sub>O line), this unique, state-of-the-art  
141 radiometer was installed on site for the first time in January 2009 (Ricaud et al., 2010a and b).  
142 The measurements of the HAMSTRAD radiometer allow the retrieval of the vertical profiles

143 of water vapour and temperature from the ground to 10-km altitude with vertical resolutions of  
144 30 to 50 m in the Planetary Boundary Layer (PBL), 100 m in the lower free troposphere and  
145 500 m in the upper troposphere-lower stratosphere. The integral along the vertical of the water  
146 vapour concentration gives the integrated water vapour (IWV). The time resolution is adjustable  
147 and fixed at 60 seconds since 2018. Note that an automated internal calibration is performed  
148 every 12 atmospheric observations and lasts about 4 minutes. Consequently, the atmospheric  
149 time sampling is 60 seconds for a sequence of 12 profiles and a new sequence starts 4 minutes  
150 after the end of the previous one. The temporal resolution on the instrument allows for detection  
151 and analysis of atmospheric processes such as the diurnal evolution of the PBL (Ricaud et al.,  
152 2012) and the presence of clouds and diamond dust (Ricaud et al., 2017) together with SLWCs  
153 (Ricaud et al., 2020). In addition, the LWP ( $\text{g m}^{-2}$ ) that gives the amount of liquid water  
154 integrated along the vertical can also be estimated. Observations of LWP have been performed  
155 when the instrument was installed at the Pic du Midi station (2877 amsl, France) during the  
156 calibration/validation period in 2008 prior to its set up in Antarctica in 2009 (Ricaud et al.,  
157 2010a) and during the Year Of Polar Prediction (YOPP) campaign in summer 2018-2019  
158 (Ricaud et al., 2020). At the present time, it has not yet been possible to compare HAMSTRAD  
159 LWP retrievals with observations from other instruments, neither at the Pic du Midi nor at  
160 Dome C stations. To better evaluate its performance, the 2021-2022 and the future 2022-2023  
161 summer campaigns are dedicated to in-situ observations of SLWCs. Comparisons with  
162 numerical weather prediction models were showing consistent amounts of LWP at Dome C  
163 when the partition function between ice and liquid water was favouring SLW for temperatures  
164 less than  $0^{\circ}\text{C}$  (Ricaud et al., 2020). Note that microwave observations at 60 and 183 GHz are  
165 not sensitive to ice crystals. This has already been discussed in Ricaud et al. (2017) when  
166 considering the study of diamond dust in Antarctica. As a consequence, possible precipitation

167 of ice, within or below SLW clouds, as detected by the LIDAR, does not affect the retrievals of  
168 temperature, water vapour and liquid water.

### 169 2.3. *AWS*

170 An American Automated Weather Station (AWS) is installed at Concordia about 500 m  
171 away from the station and can provide screen-level air temperature ( $T_a$ ) every 10 minutes. Data  
172 are freely available at <https://amrc.ssec.wisc.edu/data/archiveaws.html>.

### 173 2.4. *BSRN*

174 The BSRN sensors at Dome C are mounted at the Astroconcordia/Albedo-Rack sites, with  
175 upward and downward looking, heated and ventilated Kipp&Zonen CM22 pyranometers and  
176 CG4 pyrgeometers providing measurements of hemispheric downward and upward broadband  
177 shortwave (SW, 0.3 to 3  $\mu\text{m}$ ) and longwave (LW, 4 to 50  $\mu\text{m}$ ) horizontal irradiances at the  
178 surface, respectively. These data are used to retrieve values of net surface irradiances. All these  
179 measurements follow the rules of acquisition, quality check and quality control of the BSRN  
180 (Driemel et al., 2018).

### 181 2.5. *Period of study*

182 From the climatological study presented in Ricaud et al. (2020), the SLWCs are mainly  
183 observed above Dome C in summer, with a higher occurrence in December than in January:  
184 26% in December against 19% in January representing the percentage of days per month that  
185 SLW clouds were detected during the YOPP campaign (summer 2018-2019) within the LIDAR  
186 data for more than 12 hours per day. We have thus concentrated our analysis on December and  
187 the 4 years: 2018-2021. Since we have to use the four data sets (LIDAR, HAMSTRAD, AWS  
188 and BSRN) in time coincidence, the actual number of days per year and the time sampling for  
189 each day selected in our analysis are detailed in Table 1.

190

## 191 3. Methodology

### 192 3.1. SLWC detection

193 Consistent with Ricaud et al. (2020), we use LIDAR observations to discriminate between  
194 SLW and ice in a cloud. High values of LIDAR backscatter coefficient ( $\beta > 100 \beta_{\text{mol}}$ , with  $\beta_{\text{mol}}$   
195 the molecular backscatter) associated with very low depolarization ratio (<5%) signifies the  
196 presence of an SLWC whilst high depolarization ratio (>20%) indicates the presence of an ice  
197 cloud or precipitation. Once the SLWC is detected both in time and altitude, the temperature  
198 ( $T$ ) profile within the cloud and the LWP measured by the HAMSTRAD radiometer in time  
199 coincidence are selected together with the surface irradiances observed by the BSRN  
200 instruments.

201 The LIDAR profiles are interpolated along the temperature vertical grid and then according  
202 to the temperature time sampling. As a consequence, for a given time and height, we have a  
203 depolarization ratio, a backscatter value, a temperature as well as (not height-dependent) IWV  
204 and LWP values. BSRN irradiances are time interpolated to be coincident with the other  
205 parameters. So, for a given time, we have a set of BSRN irradiances ( $F_{LW}^{\text{Down}}$ ,  $F_{LW}^{\text{Up}}$ ,  $F_{SW}^{\text{Down}}$ ,  $F_{SW}^{\text{Up}}$   
206 and  $F_{\text{Net}}$ ) and an LWP. At a (time, height) point showing high backscatter signal and low  
207 depolarization, the associated parameters (temperature, LWP and irradiances) are flagged as  
208 “SLW cloud”. The statistic is thus done using all the SLW-flagged points without any  
209 averaging. The temperature corresponds to the in-cloud temperature.

210 Figure 1 shows, as a typical example, the time evolution of the LIDAR backscatter  
211 coefficient and depolarization ratio, as well as the HAMSTRAD LWP and temperature vertical  
212 profile for the 27 December 2021. Associated with the SLWCs, the LWP values are between  
213 1.0 and 3.0 g m<sup>-2</sup>. The SLWCs are present over a temperature range varying from about -28.0  
214 °C to -33.0 °C. Note the cloud present at 04:00-05:00 UTC that is not labelled as a SLWC but  
215 rather as an ice cloud (high backscatter and high depolarization signals) with no associated  
216 increase of LWP and temperature above -28.0 °C.

217 Figure 2 highlights the time evolution of the SLWC obtained on 27 December 2021  
 218 together with some snapshots from the HALO-CAM video camera taken with or without SLWC  
 219 on: 01:00 (no SLWC), 07:19 (SLWC), 09:00 (no SLWC), 10:14 (SLWC), 13:00 (no SLWC),  
 220 16:03 (SLWC), 18:01 (no SLWC) and 20:53 UTC (SLWC). SLWCs (high backscatter and low  
 221 depolarization signals) are clearly detected at 07:00-08:00, 10:00-11:00, 16:00-17:00, 21:00-  
 222 22:00 and 23:00-24:00 UTC over an altitude range 500 to 1000 m above ground level (agl). In  
 223 general, SLWCs observed over the station did not correspond to overcast conditions.

### 224 3.2. Cloud Radiative Forcing

225 From equation (2), one of the main difficulties in computing the cloud radiative forcing  
 226 ( $\Delta F_{Net}$ ) is to estimate  $FCF_{Net}$  from its individual components, namely the cloud-free downward  
 227 longwave, upward longwave, downward shortwave and upward shortwave surface irradiances.  
 228 We performed several studies (reference irradiances measured over days when clouds are  
 229 absent, radiative transfer calculations) from which it resulted that the most robust method was  
 230 to use a parameterization of the cloud-free downward longwave and shortwave surface  
 231 irradiances widely used in the community. In Dutton et al. (2004), cloud-free downward  
 232 shortwave surface irradiance ( $FCF_{SW}^{Down}$ ) is parameterized as:

$$233 \quad FCF_{SW}^{Down} = a \cos(z)^b c^{\left(\frac{1}{\cos(z)}\right)} \quad (3)$$

234 where  $z$  is the solar-zenith angle, and  $a$ ,  $b$ , and  $c$  are coefficients optimized using well-identified  
 235 cloud-free situations. In Dupont et al. (2008), cloud-free downward longwave surface  
 236 irradiance ( $FCF_{LW}^{Down}$ ) is parameterized as:

$$237 \quad FCF_{LW}^{Down} = \varepsilon_a \sigma T_a^4 \quad (4)$$

238 where  $T_a$  is the screen-level air temperature in Kelvin (K),  $\sigma$  the Stephan-Boltzmann's constant  
 239 and  $\varepsilon_a$  the apparent atmospheric emissivity. The latter is supposed to be a function of the  
 240 integrated water vapor (IWV) following the equation:

$$241 \quad \varepsilon_a = 1 - (1 + IWV) \exp(-(d + e \times IWV)^f) \quad (5)$$

242 where  $d$ ,  $e$  and  $f$  are coefficients that need to be optimized using cloud-free situations and IWV  
 243 is provided by the HAMSTRAD measurements. The cloud-free upward shortwave surface  
 244 irradiance ( $FCF_{SW}^{Up}$ ) is evaluated from  $FCF_{SW}^{Down}$  with the surface albedo ( $A_{BSRN} =$   
 245  $F_{SW}^{Up}(BSRN)/F_{SW}^{Down}(BSRN)$ ) calculated from observations:

$$246 \quad FCF_{SW}^{Up} = A_{BSRN} \times FCF_{SW}^{Down} \quad (6)$$

247 where  $F_{SW}^{Up}(BSRN)$  and  $F_{SW}^{Down}(BSRN)$  are the upward and downward shortwave surface  
 248 irradiance measured by the BSRN instruments, respectively. With this method, we take into  
 249 account the actual shape of the surface, and in particular its rough structure caused by the  
 250 sastrugi (see section 5.5). Thus, the surface albedo varies with the sun angles (azimutal and  
 251 zenithal) and cannot be considered as constant over the diurnal cycle.

252 The cloud-free upward longwave radiation ( $FCF_{LW}^{Up}$ ) is evaluated as:

$$253 \quad FCF_{LW}^{Up} = \varepsilon_s \sigma T_s^4 + (1 - \varepsilon_s) FCF_{LW}^{Down} \quad (7)$$

254 where  $T_s$  is the surface temperature and the surface emissivity  $\varepsilon_s$  is assumed constant and equal  
 255 to 0.99.  $T_s$  is diagnosed based on equation (7) by using the BRSN upward and downward  
 256 longwave surface irradiances.

257 Cloud-free situations are detected based on visual inspection of the LIDAR  
 258 (depolarization) measurements. Depolarization ratios greater than about 1% are attributed to  
 259 the presence of cloud (cirrus, mixed-phase, SLW), diamond dust, fog, etc. Thus, within each  
 260 24-hour slot covering the Decembers 2018-2021, the 1-hour periods when the depolarization  
 261 ratios are less than 1% are considered as cloud-free periods. Consequently, to evaluate the  
 262 surface cloud-free irradiances over the month of December and the years 2018-2021, we need  
 263 to have coincident observations from the 4 BSRN instruments, the LIDAR (depolarization),  
 264 HAMSTRAD and the AWS (see Table 1).

265 Once cloud-free situations are identified, the parametric coefficients  $a$ - $f$  are estimated  
 266 minimizing a least-square cost function using the trust region reflective method (e.g., Branch

267 et al., 1999). To assess the robustness of the estimated coefficient values, a K-fold cross-  
268 validation is performed. The learning dataset is split into 10 subsamples of equal size. Nine of  
269 them are selected to optimize the coefficient and the validation is conducted on the remaining  
270 subsample. The exercise is performed 10 times. The results are summarized below. Note that  
271 following Dupont et al. (2008),  $f$  is assumed to be equal to 1.0, and therefore not optimized.

272 For cloud-free downward shortwave surface irradiance, the K-fold cross-validation  
273 provides the following K-fold average value (K-fold minimum and maximum are indicated  
274 within brackets):  $a = 1360.7 [1360.5, 1360.8] \text{ W m}^{-2}$ ;  $b = 0.990 [0.989, 0.991]$ ;  $c = 0.964 [0.964,$   
275  $0.965]$  giving a bias of  $-0.002 [-0.317, 0.251] \text{ W m}^{-2}$  and a RMSE of  $14.9 [10.8, 16.5] \text{ W m}^{-2}$ .  
276 Similarly, for cloud-free downward longwave surface irradiance, the K-fold cross-validation  
277 provides the following results:  $d = 0.723 [0.722, 0.724]$ ;  $e = 3.58 [3.57, 3.59] \text{ kg}^{-1} \text{ m}^2$ ;  $f = 1.0$   
278 giving a bias of  $0.34 [-0.005, 0.87] \text{ W m}^{-2}$  and a RMSE of  $9.26 [8.92, 9.58] \text{ W m}^{-2}$ . These  
279 coefficient values are then used to compute cloud-free surface irradiances at a 1-min time  
280 resolution.

281 Figure 3 shows the time evolution of the cloud radiative forcing ( $\Delta F_{net}$ ) and the individual  
282 components ( $\Delta F_{LW}^{Down}$ ,  $\Delta F_{LW}^{Up}$ ,  $\Delta F_{SW}^{Down}$  and  $\Delta F_{SW}^{Up}$ ) calculated for 27 December 2021 when  
283 SLWCs are present (see Figures 1 and 2). Associated with the SLWCs, on the one hand,  
284  $\Delta F_{LW}^{Down}$  increases to values of 40 to 90  $\text{W m}^{-2}$ , whilst the impact on  $\Delta F_{LW}^{Up}$  is negligible ( $\pm 2 \text{ W}$   
285  $\text{m}^{-2}$ ). On the other hand,  $\Delta F_{SW}^{Down}$  and  $\Delta F_{SW}^{Up}$  both similarly decrease by 80 to 150  $\text{W m}^{-2}$ . The  
286 effect on  $\Delta F_{net}$  is obviously positive (0 to 80  $\text{W m}^{-2}$ ) with some weak negative values (from 0  
287 to  $-10 \text{ W m}^{-2}$ ) when SWLCs just appear or disappear that can possibly come from the  
288 inhomogeneity of the cloud distribution. Spikes can be attributed to cloud edge effects, when a  
289 fraction of the direct shortwave incident radiation and an additional diffuse contribution  
290 scattered from cloud edges fall on the radiation sensor.

291 We now want to statistically analyse all the  $\Delta F$  calculated in December 2018-2021 in order  
 292 to assess the SLWC radiative forcing as a function of LWP and to investigate the sensitivity of  
 293 the temperature inside the SLWCs as a function of LWP.

### 294 3.3. Statistical Method

295 The datasets corresponding to SLWCs periods are binned into 1°C-wide bins for in-cloud  
 296 temperature  $T$ , 0.2 g m<sup>-2</sup>-wide bins for LWP, and 5 W m<sup>-2</sup>-wide bins for  $\Delta F$ . The number of  
 297 points per bin is calculated for all the paired datasets, namely  $T$ -LWP, and  $\Delta F$ -LWP ( $\Delta F_{net}$ -  
 298 LWP,  $\Delta F_{LW}^{Down}$ -LWP,  $\Delta F_{LW}^{Up}$ -LWP,  $\Delta F_{SW}^{Down}$ -LWP and  $\Delta F_{SW}^{Up}$ -LWP). The 2D probability density  
 299 (PD) is calculated for the paired datasets and defined as  $PD_{ij} = 100 \frac{N_{ij}}{N_t}$ , where  $N_{ij}$  and  $N_t$  are  
 300 the count number in the bin  $ij$  and the total count number ( $N_t = \sum_{j=1}^N \sum_{i=1}^M N_{ij}$ ), respectively,  
 301 with  $M$  and  $N$  being the total number of bins in LWP on one side, and in temperature or  $\Delta F$  on  
 302 the other side, respectively. So, for each value of  $T_j$  (within a 1°C-wide bin  $j$ ) or  $\Delta F_j$  (within a  
 303 5 W m<sup>-2</sup>-wide bin  $j$ ), a weighted average of LWP ( $\overline{LWP_j}$ ) is calculated together with its  
 304 associated weighted standard deviation ( $\sigma_{LWP_j}$ ), considering all the  $LWP_{ij}$  values (within 0.2 g  
 305 m<sup>-2</sup>-wide bins) from  $i=1$  to  $M$ , with  $M$  the total number of LWP bins and  $w_{ij}$  the weight, namely  
 306 the number of points ( $w_{ij} = N_{ij}$ ), associated to the bin  $ij$ :

$$307 \quad \overline{LWP_j} = \frac{\sum_{i=1}^M w_{ij} LWP_{ij}}{\sum_{i=1}^M w_{ij}} \quad (8)$$

308 and

$$309 \quad \sigma_{LWP_j} = \sqrt{\frac{\sum_{i=1}^M w_{ij} (LWP_{ij} - \overline{LWP_j})^2}{\sum_{i=1}^M w_{ij}}} \quad (9)$$

310 For each  $T$  and  $\Delta F$  dataset, the distribution of the total count numbers  $N_{tj}$  per 1°C or  
 311 5 W m<sup>-2</sup>-wide bin ( $N_{tj} = \sum_{i=1}^M N_{ij}$  with  $j = 1, \dots, N$ ) can be fitted by a function  $N(x)$ , with  $x =$   
 312  $T$  or  $\Delta F$ , based on 2 to 3 Gaussian distributions as:

313 
$$N(x) = \sum_{k=1}^{2 \text{ or } 3} a_k \exp\left(-\frac{1}{2}\left(\frac{x-\mu_k}{\sigma_k}\right)^2\right) + c_0 \quad (10)$$

314 with  $a_k$ ,  $\mu_k$  and  $\sigma_k$  being the amplitude, the mean and the standard deviation of the  $k^{\text{th}}$  Gaussian  
 315 function and  $c_0$  is a constant. We have used 0, 2 or 3 Gaussians for  $\Delta F$  components and 3  
 316 Gaussians for  $T$  (“0” means that no Gaussian fit was meaningful). Table 2 lists all the fitted  
 317 parameters ( $a_k$ ,  $\mu_k$ ,  $\sigma_k$  and  $c_0$  with  $k = 0$  to 3).

318 In the relationship between  $x$  ( $T$  or  $\Delta F$ ) and LWP, we have considered  $x_j$  ( $T_j$  or  $\Delta F_j$ ) to be  
 319 significant when:

320 
$$|x_j - \mu_k| \leq \sigma_k \text{ for } k = 1 - 2 \text{ or } 3 \text{ (for } \Delta F) \text{ or } 1 - 3 \text{ (for } T) \quad (11)$$

321 and used for this significant point its average value and standard deviation,  $\overline{LWP}_j$  and  $\sigma_{LWP_j}$ ,  
 322 respectively, with  $j = 1, \dots, N$ .

323 Finally, a logarithmic function of the form

324 
$$x = \alpha + \beta \ln(\overline{LWP}) \quad (12)$$

325 has been fitted onto these significant points where the retrieved constants  $\alpha$  and  $\beta$  are shown in  
 326 Table 3 for  $x$  being  $T$ ,  $\Delta F_{net}$ ,  $\Delta F_{LW}^{Down}$ ,  $\Delta F_{LW}^{Up}$ ,  $\Delta F_{SW}^{Down}$  and  $\Delta F_{SW}^{Up}$ .

327

## 328 4. Results

### 329 4.1. Temperature-Liquid Water Relationship in SLWCs

330 The relationship between temperature and LWP within SLWCs over the 4-summer period  
 331 at Dome C is presented Figure 4 left in the form of a Probability Density (PD) that is the fraction  
 332 of points within each bin of  $0.2 \text{ g m}^{-2}$  width in LWP and  $1.0^\circ\text{C}$  width in temperature. It clearly  
 333 shows a net tendency for liquid water to increase with temperature, up to  $\sim 14 \text{ g m}^{-2}$  in LWP and  
 334  $-18^\circ\text{C}$  in temperature, with two zones having a density as high as  $\sim 2\%$ , at  $[0.5 \text{ g m}^{-2}, -33^\circ\text{C}]$   
 335 and  $[1.5 \text{ g m}^{-2}, -32^\circ\text{C}]$ . We have performed a weighted average of the LWPs within each  
 336 temperature bin (Figure 4 centre). Then, we have fitted 3 Gaussian distributions to the count

337 numbers as a function of temperature (Figure 4 right). If we now only consider temperature  
338 bins within one-sigma of the centre of the Gaussian distributions, we can fit the following  
339 logarithmic relation of the temperature  $T$  as a function of LWP within the SLWC (Figure 4  
340 centre):

$$341 \quad T(LWP) = -33.8 (\pm 1.5) + 6.5 \ln(LWP) \quad (13)$$

342 for  $T \in [-36; -16]$  °C and  $LWP \in [1.0; 14.0]$  g m<sup>-2</sup>, with a validity range indicated by the  
343 2 blue dashed lines ( $\pm 1.5$  °C) in Figure 4 centre. In other words, based on our study, we have  
344 a clear evidence that supercooled liquid water content exponentially increases with temperature.  
345 Considering the temperature vs. LWP relationship, the two main Gaussian distributions are  
346 centered around -28°C and -30°C, corresponding to temperatures usually encountered in  
347 Concordia whilst the third one, far much less intense, is centered around -18°C, probably the  
348 signature of very unusual events occurring in Concordia as the warm-moist events. Episodes of  
349 warm-moist intrusions exist above Concordia originated from mid-latitudes (Ricaud et al., 2017  
350 and 2020) and are known as “atmospheric rivers” (Wille et al., 2019). Although they are  
351 infrequent, they can provide high values of temperature and LWP.

#### 352 *4.2. Radiative Forcing-Liquid Water Relationship in SLWC conditions*

353 Although the amount of LWP is very low ( $< 20$  g m<sup>-2</sup>) at Dome C compared to what can  
354 be measured and modelled (Lemus et al., 1997) in the Arctic (50 to 75 g m<sup>-2</sup>) and at  
355 middle/tropical latitudes (100 to 150 g m<sup>-2</sup>), we intended to estimate its impact on the cloud  
356 radiative forcing at Dome C. In Figures 5 to 9, the left panel presents the PDs of the cloud  
357 radiative forcing  $\Delta F_{net}$  as a function of the LWP, and for the individual components that  
358 contribute to the cloud radiative forcing:  $\Delta F_{LW}^{Down}$ ,  $\Delta F_{LW}^{Up}$ ,  $\Delta F_{SW}^{Down}$  and  $\Delta F_{SW}^{Up}$ , respectively. The  
359 central panel shows, for the same parameters, the corresponding weighted average LWP within  
360 5 W m<sup>-2</sup>-wide bins of  $\Delta F$  whereas the right panel shows the corresponding count number within

361 5 W m<sup>-2</sup>-wide bins fitted by 2 or 3 Gaussian distributions (or no Gaussian distribution when it  
 362 becomes impossible).

363 Based on our analysis, the relationship between  $\Delta F_{net}$  (W m<sup>-2</sup>) and the LWP (g m<sup>-2</sup>) has  
 364 been estimated as:

$$365 \quad \Delta F_{net}(LWP) = -18.0 (\pm 10.0) + 70.0 \ln(LWP) \quad (14)$$

366 for  $\Delta F_{net} \in [0; 70]$  W m<sup>-2</sup> and  $LWP \in [1.2; 3.0]$  g m<sup>-2</sup>, with a validity range indicated the two  
 367 blue dashed lines ( $\pm 10.0$  W m<sup>-2</sup>) in Figure 5 centre. Thus, for LWP greater than 1.2 g m<sup>-2</sup>, our  
 368 study clearly shows that the cloud radiative forcing induced by the presence of SLWCs above  
 369 Concordia is positive and can reach 70 W m<sup>-2</sup> for an LWP of 3.0 g m<sup>-2</sup>.

370 The splitting of the cloud radiative forcing between each of its four components can be  
 371 evaluated from their individual relationships with the LWP. These relations are gathered in  
 372 Table 3, established from the plots presented in Figures 5 to 9. They are of the same form as  
 373 for cloud radiative forcing, i.e. a logarithmic dependence on LWP. Table 3 presents the  
 374 coefficients  $\alpha$  and  $\beta$  of the logarithmic function  $f(LWP) = \alpha + \beta \ln(LWP)$  for the temperature  
 375  $T$  or the radiation components  $\Delta F$ , together with the valid range of these relations for  $T$ ,  $\Delta F$  and  
 376 LWP. For the values presented in Table 3, our study clearly shows that SLWCs have a positive  
 377 impact on  $\Delta F_{LW}^{Down}$  increasing from 0 to 90 W m<sup>-2</sup> for LWP ranging from 1.0 to 3.5 g m<sup>-2</sup>, a  
 378 negative impact on  $\Delta F_{SW}^{Down}$  and  $\Delta F_{SW}^{Up}$  decreasing from 0 to -130 and -110 W m<sup>-2</sup>, respectively  
 379 for LWP ranging from 1.5 to 4.0 g m<sup>-2</sup>, and negligible impact ( $\pm 5$  W m<sup>-2</sup>) on  $\Delta F_{LW}^{Up}$  for LWP  
 380 ranging from 0 to 6.5 g m<sup>-2</sup>. Considering the absolute values of  $\Delta F$  vs. LWP relationship  
 381 (keeping aside  $\Delta F_{LW}^{Up}$ ), we have systematically the most intense Gaussian distributions centered  
 382 at  $\sim 10$  W m<sup>-2</sup>, and the other ones centered at  $\sim 55$  W m<sup>-2</sup> and  $\sim 80$  W m<sup>-2</sup>.

383 To synthetize, our study showed that the major impact of SLWCs on net surface irradiance  
 384 is an increase of downward longwave component (0 to 80 W m<sup>-2</sup>), whereas it has a marginal  
 385 impact on upward longwave component since this parameter is mainly dependent on  $T_s$  which

386 results from various meteorological forcings. In the presence of SLWC, the attenuation of  
387 shortwave incoming irradiance (which can overpass  $100 \text{ W m}^{-2}$ ) is almost compensated for by  
388 the upward shortwave irradiance because of high values of surface albedo.

389 We can also estimate the sensitivity of the longwave component to temperature and  
390 humidity by considering the values of the equivalent atmospheric emissivity  $\varepsilon_a$  used in the  
391 equations 4-7. On the one side, the values of IWV observed at Dome C are very low even in  
392 summer, typical summertime values are between  $0.8$  and  $1.2 \text{ kg m}^{-2}$  (Ricaud et al., 2020). This  
393 corresponds to values of  $\varepsilon_a$  between  $0.950$  and  $0.985$ , i.e. a relative variation of the order of  
394  $3.6\%$ . On the other side, a variation  $\Delta T$  of the screen-level air (surface) temperature  $T_a$  ( $T_s$ ) has  
395 a relative impact on the downwelling (upwelling) longwave irradiance of the order of  $4 \Delta T/T_a$   
396 ( $4 \Delta T/T_s$ ), which amounts to around  $1.6\%$  per degree of  $\Delta T$ . Given that observations of surface  
397 and screen-level air temperatures reveal variations of several degrees, both in their diurnal cycle  
398 and from a day to another, we can conclude that the impact of temperature on longwave  
399 irradiance variations is larger than that of IWV.

400

## 401 **5. Discussion**

### 402 *5.1 Relation with critical temperature*

403 Our study shows that, above Concordia, there is an exponential dependence of LWP on both  
404 temperature and cloud radiative forcing, that is to say supercooled liquid water exponentially  
405 increases with temperature in the range  $-36^\circ\text{C}$  to  $-16^\circ\text{C}$ . This is in agreement with the outputs  
406 from a simple model for thermodynamic properties of water from sub-zero temperatures up to  
407  $+100^\circ\text{C}$  (Sippola and Taskinen, 2018). The model shows that the density  $\rho$  ( $\text{g cm}^{-3}$ ) of liquid  
408 water exponentially increases with temperature from  $-34^\circ\text{C}$  to  $0^\circ\text{C}$  through the following  
409 relationship:

$$410 \quad \rho = \rho_0 \exp\{-T_c(A + B\varepsilon_0 + 2C\varepsilon_0^{1/2})\} \quad (15)$$

411 where  $\rho_0 = 1.007853 \text{ g cm}^{-3}$ ,  $A = 3.9744 \cdot 10^{-4} \text{ K}^{-1}$ ,  $B = 1.6785 \cdot 10^{-3} \text{ K}^{-1}$ , and  $C = -7.8165 \cdot 10^{-4} \text{ K}^{-1}$ ;  
412  $T_c$  is the critical temperature (K) and  $\varepsilon_0$  (unitless) is defined as:

$$413 \quad \varepsilon_0 = \frac{T}{T_c} - 1 \quad (16)$$

414 where  $T$  is temperature in K. In thermodynamics, a critical point is the end point of a phase  
415 equilibrium curve. In our study, the liquid–ice boundary terminates at some critical temperature  
416  $T_c$ .  $T_c$  is about 224.8 K if water is pure and free of nucleation nuclei. Sippola and Taskinen  
417 (2018) reviewed a value of  $T_c \sim 227\text{-}228 \text{ K}$  (approx.  $-45^\circ\text{C}$ ) in the literature. This is also in  
418 agreement with the results from our study showing that, above Concordia, we could not  
419 observed SLWCs at temperatures less than  $-36^\circ\text{C}$  consistent with the fact that the threshold  
420 temperature to get SLWCs should be around  $-39^\circ\text{C}$  (see the discussions on errors in section  
421 5.3).

## 422 5.2. Modelling SLWC

423 Previous studies have already underlined the difficulty to model the SLWC together with  
424 its impact on surface radiations. Modelling SLWCs over Antarctica is challenging because 1)  
425 operational observations are scarce since the majority of meteorological radiosondes are  
426 released from ground stations located at the coast and very few of them are maintained all year  
427 long, and satellite observations are limited to  $60^\circ\text{S}$  in geostationary orbit whilst, in a polar orbit,  
428 the number of available orbits does not exceed 15 per day, and 2) the model should provide a  
429 partition function favouring liquid water at the expense of ice for temperatures between  $-36^\circ\text{C}$   
430 and  $0^\circ\text{C}$  in order to calculate realistic SLW contents. Differences of 20 to  $50 \text{ W m}^{-2}$  in the net  
431 surface irradiance were found in the Arpege model (Pailleux et al., 2015) between clouds made  
432 of ice or liquid water during the summer 2018-2019 (Ricaud et al., 2020), differences that are  
433 very consistent with the results obtained in the present study. Although SLWCs are less present  
434 over the Antarctic Plateau than over the coastal region, their radiative impact is not negligible

435 and should be taken into account with great care in order to estimate the radiative budget of the  
436 Antarctic continent in one hand, and, on the other hand, over the entire Earth.

### 437 5.3. Errors

438 Measurements of temperature, LWP, depolarization signal and surface irradiances  $F$  are  
439 altered by random and systematic errors that may affect the relationships we have obtained  
440 between LWP and either temperature or cloud radiative forcing  $\Delta F_{net}$  and its individual  
441 components. The temperature measured by HAMSTRAD below 1 km has been evaluated  
442 against radiosonde coincident observations from 2009 to 2014 (Ricaud et al., 2015) and the  
443 resulting bias is 0 to 2°C below 100 m and between -2 and 0°C between 100 and 1000 m.  
444 SLWCs are usually located around 400-600 m above the ground where the cold bias can be  
445 estimated to be about -1.0°C. The one-sigma ( $1-\sigma$ ) RMS temperature error over a 7-min  
446 integration time is 0.25°C in the PBL and 0.5°C in the free troposphere (Ricaud et al., 2015).  
447 As a consequence, given the number of points used in the statistical analysis (>1000), the  
448 random error on the weighted-average temperature is negligible (<0.02°C). The LWP random  
449 and systematic errors are difficult to evaluate since there is no coincident external data to  
450 compare with. Nevertheless, the  $1-\sigma$  RMS error over a 7-min integration time can be estimated  
451 to be 0.25 g m<sup>-2</sup> giving a random error on the weighted average LWP less than 0.08 g m<sup>-2</sup>. Based  
452 on clear-sky observations, the positive bias can be estimated to be of the order of 0.4 g m<sup>-2</sup>.  
453 Theoretically, SLW should not exist at temperatures less than -39°C although it has been  
454 observed in recent laboratory measurements down to -42.55°C (Goy et al., 2018). Using  
455 equation (13) with an LWP bias of 0.4 g m<sup>-2</sup> gives a temperature of -39.8°C (~0.8°C lower than  
456 the theoretical limit of -39°C), so the biases estimated for temperature and LWP are very  
457 consistent with theory.

458 The estimation of systematic and random errors on LIDAR backscattering and  
459 depolarization signals and their impact on the attribution/selection of SLWC is not trivial. But

460 the most important point is to evaluate whether the observed cloud is constituted of purely liquid  
461 or mixed-phase water. Even considering the backscatter intensity only, we could not exclude  
462 that ice particles could have been present in the SLWC events investigated in 2018 (Ricaud et  
463 al., 2020). Therefore, in the present analysis, although we made a great attention to diagnose  
464 ice in the LIDAR cloud observations, we cannot totally exclude ice particles thus mixed-phase  
465 parcels were actually present when we labelled the observed cloud as SLWCs.

466 The 4 instruments providing  $F_{LW}^{Down}$ ,  $F_{LW}^{Up}$ ,  $F_{SW}^{Down}$ , and  $F_{SW}^{Up}$  follow the rules of acquisition,  
467 quality check and quality control of the BSRN (Driemel et al., 2018). These data are often  
468 considered as a reference against which products based on satellite observations and radiative  
469 transfer models (such as e.g. CERES) are validated (Kratz et al., 2020). In polar regions  
470 (Lanconelli et al., 2011),  $F_{SW}^{Down}$  and  $F_{SW}^{Up}$  are expected to be affected by random errors up to  
471  $\pm 20 \text{ W m}^{-2}$  while  $F_{LW}^{Down}$  are expected to be affected by random errors not greater than  $\pm 10 \text{ W}$   
472  $\text{m}^{-2}$  (Ohmura et al., 1998). As a consequence, given the large number of observations used per  
473  $5 \text{ W m}^{-2}$ -wide bins (1000-3000), the random error on the weighted-average  $F$  is negligible (0.3  
474 to  $0.7 \text{ W m}^{-2}$ ) whatever the radiations considered, LW and SW.

475 Finally, another source of error comes from 1) the geometry of observation and 2) the  
476 discontinuous SLWC layer. Firstly, LIDAR is almost zenith pointing, HAMSTRAD makes a  
477 scan in the East direction (from  $10^\circ$  elevation to zenith), whilst the BSRN radiometers detect  
478 the radiation in a  $2\pi$ -steradians field of view (3D configuration). That is to say, in our analysis,  
479 the whole sky contributes to the radiation whilst only the cloud at zenith (1D configuration) and  
480 on the East direction (2D configuration) is observed by the LIDAR and HAMSTRAD,  
481 respectively. Secondly, SLWCs cannot be considered as uniform in the whole (see e.g. broken  
482 cloud fields in Figure 2).

483 *5.4. Other clouds*

484        Although the method we have developed to select the SLWCs has been validated using the  
485 amount of LWP and, in another study, using space-borne observations (Ricaud et al., 2020), we  
486 cannot rule out that, associated with the SLW droplets, are also ice particles, that is clouds are  
487 constituted of a mixture of liquid and solid water. Statistics of ice and mixed-phase clouds over  
488 the Antarctic Plateau have been performed by Cossich et al. (2021) revealing mean annual  
489 occurrences of 72.3 %, 24.9 %, and 2.7 % for clear sky, ice clouds, and mixed-phase clouds,  
490 respectively. Generally, mixed-phase clouds are a superposition of a lower layer being made of  
491 liquid water and an upper layer being made of solid water (see Fig. 12.3 from Lamb and  
492 Verlinde, 2011). These mixed-layer clouds do not significantly modify the relationship between  
493 temperature and LWP because 1) SLW observations from HAMSTRAD are only sensitive to  
494 water in liquid phase and 2) temperature from HAMSTRAD is selected at times and vertical  
495 heights where the LIDAR depolarization signal is very low (<5%). Although we have verified  
496 that pure ice clouds were not selected by our method, we cannot differentiate mixed-phase  
497 clouds from purely SLWCs.

498        Furthermore, we already have noticed that SLWCs developed at the top of the PBL (Ricaud  
499 et al., 2020) in the “entrainment zone” and maintained in the “capping inversion zone”,  
500 following the terminology of Stull (1988), at a height ranging from 100 to 1000 m above ground  
501 level. Nevertheless, at 00:00-06:00 LT when the sun is at low elevation above the horizon (24-  
502 h polar day), the PBL may collapse down to a very low height ranging 20-50 m. In this  
503 configuration, it is hard to differentiate from LIDAR observations between a SLWC and a fog  
504 episode, although the LIDAR can measure depolarization (but not backscatter) down to  
505 approximately 10-30 m above the ground (Figure S3 in Chen et al., 2017), so that we can  
506 distinguish liquid/frozen clouds very close to the ground.

507        Finally, we cannot rule out that, above the SLWCs that are actually observed by both  
508 LIDAR and HAMSTRAD, other clouds might be present, as e.g. cirrus clouds constituted of

509 ice crystals. These mid-to-upper tropospheric clouds cannot be detected by HAMSTRAD (no  
510 sensitivity to ice crystals). In the presence of SLWCs either low in altitude or optically thick,  
511 the LIDAR backscatter signal is decreased in order to avoid saturation and the signal from upper  
512 layers is thus almost cancelled. These mid-to-high-altitude clouds are sensed by the BSRN  
513 instruments and surface irradiance can be affected in this configuration. Based on the presence  
514 of cirrus clouds before or after the SLWCs (and sometimes during the SLWCs if optically thin),  
515 we can estimate that the number of days when SLWCs and cirrus clouds are simultaneously  
516 present to cover less than 10% of our period of interest.

### 517 *5.5. Sastrugi effect on the surface albedo*

518 Sastrugi are features formed by erosion of snow by wind. They are found in polar regions,  
519 and in snowy, wind-swept areas of temperate regions, such as frozen lakes or mountain ridges.  
520 Sastrugi are distinguished by upwind-facing points, resembling anvils, which move downwind  
521 as the surface erodes.

522 Figure 10 shows the BSRN surface albedo averaged over the five cloud-free days (2 and  
523 19 December 2018; 3, 17 and 26 December 2021) showing a clear diurnal signal with a  
524 maximum of 0.85 from 10:00 to 14:00 UTC (from 18:00 to 22:00 LT) and a minimum of 0.70  
525 from 19:00 to 23:00 UTC (from 03:00 to 07:00 LT). The large diurnal signal present in the  
526 observed surface albedo is likely the signature of 1) the sastrugi orientation and also 2) the sun  
527 zenith angle which impacts on the surface albedo even with a flat snow surface (Gardner and  
528 Sharp, 2010). Note that the surface albedo of snow under cloudy conditions may differ from  
529 the surface albedo under cloud-free conditions (e.g., Gardner and Sharp, 2010; Stapf et al.,  
530 2020). The BSRN  $F_{SW}^{Up}$  sensor has a circular footprint. For a sensor installed at a height  $h$  above  
531 the ground, 90% of the signal comes from an area at the surface closer than  $3.1 h$  (Kassianov et  
532 al., 2014). Since at Dome-C the instrument is installed at a height of 2-3 m, the albedo is thus  
533 determined by the surface elements in the immediate vicinity (a few meters) of the sensor.

534 We have fitted the averaged cloud-free BSRN surface albedo with the sum of two sine  
 535 functions, imposing periods of 24 and 12 hours (Figure 10) together with the residuals between  
 536 the averaged surface albedo and the fitted function. We can state that the sastrugi effect on the  
 537 observed cloud-free surface albedo at Concordia is successfully fitted by two sine functions of  
 538 24h and 12h periods to within 0.003 mean absolute error, with a coefficient of determination  
 539  $R^2$  equal to 0.993 and a root mean square error of 0.0004.

540 Moreover, we have considered all the BSRN observations in Decembers 2018, 2019, 2020  
 541 and 2021 to calculate the albedo (Figure 11), and we have superimposed the fitted trigonometric  
 542 function as described in Figure 10. The presence of clouds is well highlighted by observations  
 543 that depart from the fitted function whilst, during periods of clear-sky conditions, BSRN  
 544 albedos coincide well with the fitted function. To conclude, the surface albedo at Concordia  
 545 should be treated considering sastrugi effect.

#### 546 5.6. Maximum SLWC Radiative Forcing over Antarctica

547 Based on 2007-2010 reanalyses, observations and climate models (Lenaerts et al., 2017),  
 548 LWP over Antarctica is on average less than  $10 \text{ g m}^{-2}$ , with slightly larger values in summer  
 549 than in winter by 2 to  $5 \text{ g m}^{-2}$ . Over Western Antarctica, LWPs are larger (20 to  $40 \text{ g m}^{-2}$ ) than  
 550 over Eastern Antarctica (0 to  $10 \text{ g m}^{-2}$ ). As a consequence, LWPs observed at Concordia are  
 551 consistent with values observed over the Eastern Plateau, with a factor 2 to 4 smaller than those  
 552 observed over the Western continent. Based on our results and on the observed cloud fraction  
 553 ( $\eta_{CF}$ ) of SLWCs over Antarctica for different seasons (Listowski et al., 2019), we can estimate  
 554 the maximum SLWC radiative forcing at the scale of the Antarctic continent ( $\Delta F_{Net-Ant}^{max}$ ) from  
 555 the maximum of  $\Delta F_{net}$  ( $\Delta F_{Net}^{max} = 70 \text{ W m}^{-2}$ ) computed in our study:

$$556 \quad \Delta F_{Net-Ant}^{max} = \eta_{CF} \times \Delta F_{Net}^{max} \quad (17)$$

557 Equation (17) assumes a linear dependence between cloud fraction and cloud radiative forcing  
 558 although, in nature, there could be three-dimensional radiation effects. In summer,  $\eta_{CF}$  is

559 varying from 5% in Eastern Antarctica to 40% in Western Antarctica whilst, in winter, it is  
560 varying from 0% in Eastern Antarctica to 20% in Western Antarctica (Listowski et al., 2019).  
561 In December, if we consider  $\eta_{CF}$  for SLW-containing cloud (that is to say both mixed-phase  
562 cloud and unglaciated SLW cloud consistent with our study), we find for a lower-level altitude  
563 cut-off of 0, 500 and 1000 m (Figure B1 in Listowski et al., 2019), a maximum SLWC radiative  
564 forcing  $\Delta F_{Net-Ant}^{max}$  over Antarctica of about  $12 \text{ W m}^{-2}$ ,  $10 \text{ W m}^{-2}$  and  $7 \text{ W m}^{-2}$ , respectively. We  
565 now separate the Eastern elevated Antarctic Plateau from the Western Antarctica (Figure 5 in  
566 Listowski et al., 2019) for the 4 seasons. Over Eastern Antarctica, we find that  $\Delta F_{Net-Ant}^{max} = 0.7$   
567 to  $7.0 \text{ W m}^{-2}$  in December-January-February (DJF) and 0 to  $3.5 \text{ W m}^{-2}$  for the remaining  
568 seasons. Over Western Antarctica, the maximum radiative impact is much more intense because  
569 of higher temperatures and lower elevations compared to the Eastern Antarctic Plateau:  
570  $\Delta F_{Net-Ant}^{max} = 17.5$  to  $40.0 \text{ W m}^{-2}$  in DJF ( $40 \text{ W m}^{-2}$  over the Antarctica Peninsula);  $10.5$  to  $28.0$   
571  $\text{W m}^{-2}$  in March-April-May;  $3.5$  to  $14.0 \text{ W m}^{-2}$  in June-July-August; and  $7.0$  to  $17.5 \text{ W m}^{-2}$  in  
572 September-October-November. To summarize, the maximum SLWC radiative forcing over  
573 Western Antarctica ( $0$  to  $40 \text{ W m}^{-2}$ ) is estimated to 3 to 5 times larger compared to the one over  
574 the Eastern Antarctic Plateau ( $0$  to  $7 \text{ W m}^{-2}$ ), maximizing during the summer season.

575

## 576 **6. Conclusions**

577 Combining the observations of temperature, water vapour and liquid water path from a  
578 ground-based microwave radiometer, backscattering and depolarization from a ground-based  
579 LIDAR, screen-level air temperature and surface radiations at long and short wavelengths, our  
580 analysis has been able to evaluate the presence of supercooled liquid water clouds over the  
581 Dome C station in summer. Focusing on the month of December in 2018-2021, we established  
582 that in SLWCs temperature logarithmically increases from  $-36.0^\circ\text{C}$  to  $-16.0^\circ\text{C}$  when LWP  
583 increases from  $1.0$  to  $14.0 \text{ g m}^{-2}$ . We have also evaluated that SLWCs have a positive cloud

584 radiative forcing, which logarithmically increases from 0.0 to 70.0 W m<sup>-2</sup> when LWP increases  
585 from 1.2 to 3.5 g m<sup>-2</sup>. Our study clearly shows that SLWCs have a positive impact on  $\Delta F_{LW}^{Down}$   
586 increasing from 0 to 90 W m<sup>-2</sup> for LWP ranging from 1.0 to 3.5 g m<sup>-2</sup>, a negligible impact ( $\pm 5$   
587 W m<sup>-2</sup>) on  $\Delta F_{LW}^{Up}$  for LWP ranging from 0 to 6.5 g m<sup>-2</sup>, and a negative (but quite offsetting)  
588 impact on each of the two terms  $\Delta F_{SW}^{Down}$  and  $\Delta F_{SW}^{Up}$  which decrease from 0 to -130 and -110  
589 W m<sup>-2</sup>, respectively for LWP ranging from 1.5 to 4.0 g m<sup>-2</sup>. This means that the SLWC radiative  
590 forcing is mainly driven by the downward surface irradiance since the attenuation of shortwave  
591 incoming irradiance is almost compensated for by the upward shortwave irradiance because of  
592 high values of surface albedo.

593 Finally, extrapolating our results of the SLWC radiative forcing from the Dome C station  
594 to the Antarctic continent shows that the maximum SLWC radiative forcing is not greater than  
595 7.0 W m<sup>-2</sup> over the Eastern Antarctic Plateau but 2 to 3 times larger (up to 40 W m<sup>-2</sup>) over  
596 Western Antarctica, maximizing over in summer season and over the Antarctic Peninsula. This  
597 stresses the importance of accurately modelling SLWCs when calculating the Earth energy  
598 budget to adequately forecast the Earth climate evolution, especially since the climate is rapidly  
599 changing in Antarctica, as illustrated by the surface temperature record of -12°C recently  
600 observed in March 2022 at the Concordia station and largely publicized worldwide (see e.g.  
601 [https://www.9news.com.au/world/antarctica-heatwave-extreme-warm-weather-recorded-](https://www.9news.com.au/world/antarctica-heatwave-extreme-warm-weather-recorded-concordia-research-station/3364dd91-2051-4df5-8cfc-5f2819058604)  
602 [concordia-research-station/3364dd91-2051-4df5-8cfc-5f2819058604](https://www.9news.com.au/world/antarctica-heatwave-extreme-warm-weather-recorded-concordia-research-station/3364dd91-2051-4df5-8cfc-5f2819058604)).

603

#### 604 **Data availability**

605 HAMSTRAD data are available at <http://www.cnrm.meteo.fr/spip.php?article961&lang=en>  
606 (last access: 27 November 2023). The tropospheric depolarization LIDAR data are reachable  
607 at <http://lidarmax.altervista.org/lidar/home.php> (last access: 27 November 2023). Radiosondes  
608 are available at <http://www.climantartide.it> (last access: 27 November 2023). Screen-level air

609 temperature from AWS can be obtained from the ftp server  
610 (<https://amrc.ssec.wisc.edu/data/archiveaws.html>) (last access: 27 November 2023). BSRN  
611 data can be obtained from the ftp server (<https://bsrn.awi.de/data/data-retrieval-via-ftp/>) (last  
612 access: 27 November 2023).

613

#### 614 **Author contribution**

615 PR, MDG, and AL provided the observational data. PR developed the methodology. All the  
616 co-authors participated in the data analysis and in the data interpretation. PR prepared the  
617 manuscript with contributions from all co-authors.

618

#### 619 **Competing interests**

620 The authors declare that they have no conflict of interest.

621

#### 622 **Acknowledgments**

623 The present research project Water Budget over Dome C (H<sub>2</sub>O-DC) has been approved by  
624 the Year of Polar Prediction (YOPP) international committee. The HAMSTRAD programme  
625 (910) was supported by the French Polar Institute, Institut polaire français Paul-Emile Victor  
626 (IPEV), the Institut National des Sciences de l'Univers (INSU)/Centre National de la Recherche  
627 Scientifique (CNRS), Météo-France and the Centre National d'Etudes Spatiales (CNES). The  
628 permanently manned Concordia station is jointly operated by IPEV and the Italian Programma  
629 Nazionale Ricerche in Antartide (PNRA). The tropospheric LIDAR operates at Dome C from  
630 2008 within the framework of several Italian national (PNRA) projects. We would like to thank  
631 all the winterover personnel who worked at Dome C on the different projects: HAMSTRAD,  
632 aerosol LIDAR and BSRN. We would like to thank the three anonymous reviewers for their  
633 beneficial comments.

**Tables**

801 **Table 1.** Cloud-free periods in December 2018-2021 detected from the LIDAR depolarization  
 802 observations at Concordia. Time is in UTC. MM-NN means from MM (included) hour UTC to  
 803 NN (excluded) hour UTC. “X” means no cloud-free period during that day. “ND” means no  
 804 LIDAR data available. Bold cases mean that cloud-free irradiance calculations are impossible  
 805 due to lack of some data (LIDAR, HAMSTRAD, BSRN or AWS).

808

809 **Table 2.** Gaussian functions fitted to the  $N(x)$  function for  $x = T$  ( $^{\circ}\text{C}$ ) or  $\Delta F$  ( $\text{W m}^{-2}$ ). Units of810  $a_1$ ,  $a_2$ ,  $a_3$ , and  $c_0$  are in count number for  $T$  and  $\Delta F$ ; units of  $\mu_1$ ,  $\mu_2$ ,  $\mu_3$ ,  $\sigma_1$ ,  $\sigma_2$ , and  $\sigma_3$  are in811  $^{\circ}\text{C}$  for  $T$  and in  $\text{W m}^{-2}$  for  $\Delta F$ .

$x$	$a_1$	$\mu_1$	$\sigma_1$	$a_2$	$\mu_2$	$\sigma_2$	$a_3$	$\mu_3$	$\sigma_3$	$c_0$
$T$	$15.0 \cdot 10^3$	-31.5	1.45	$5.0 \cdot 10^3$	-28.0	1.65	$0.5 \cdot 10^3$	-19.0	2.5	$-9.1 \cdot 10^{-6}$
$\Delta F_{net}$	371.7	10.0	11.5	74.6	37.6	21.1	220.8	57.5	14.1	-10.2
$\Delta F_{LW}^{Down}$	415.5	10.0	10.4	189.5	53.7	24.2	227.1	82.9	7.0	-18.5
$\Delta F_{LW}^{Up}$	-	-	-	-	-	-	-	-	-	-
$\Delta F_{SW}^{Down}$	190.5	-10.1	17.2	113.0	-80.0	54.6	-	-	-	-1.9
$\Delta F_{SW}^{Up}$	282.4	-10.1	12.8	133.8	-75.0	41.8	-	-	-	8.3

812

813

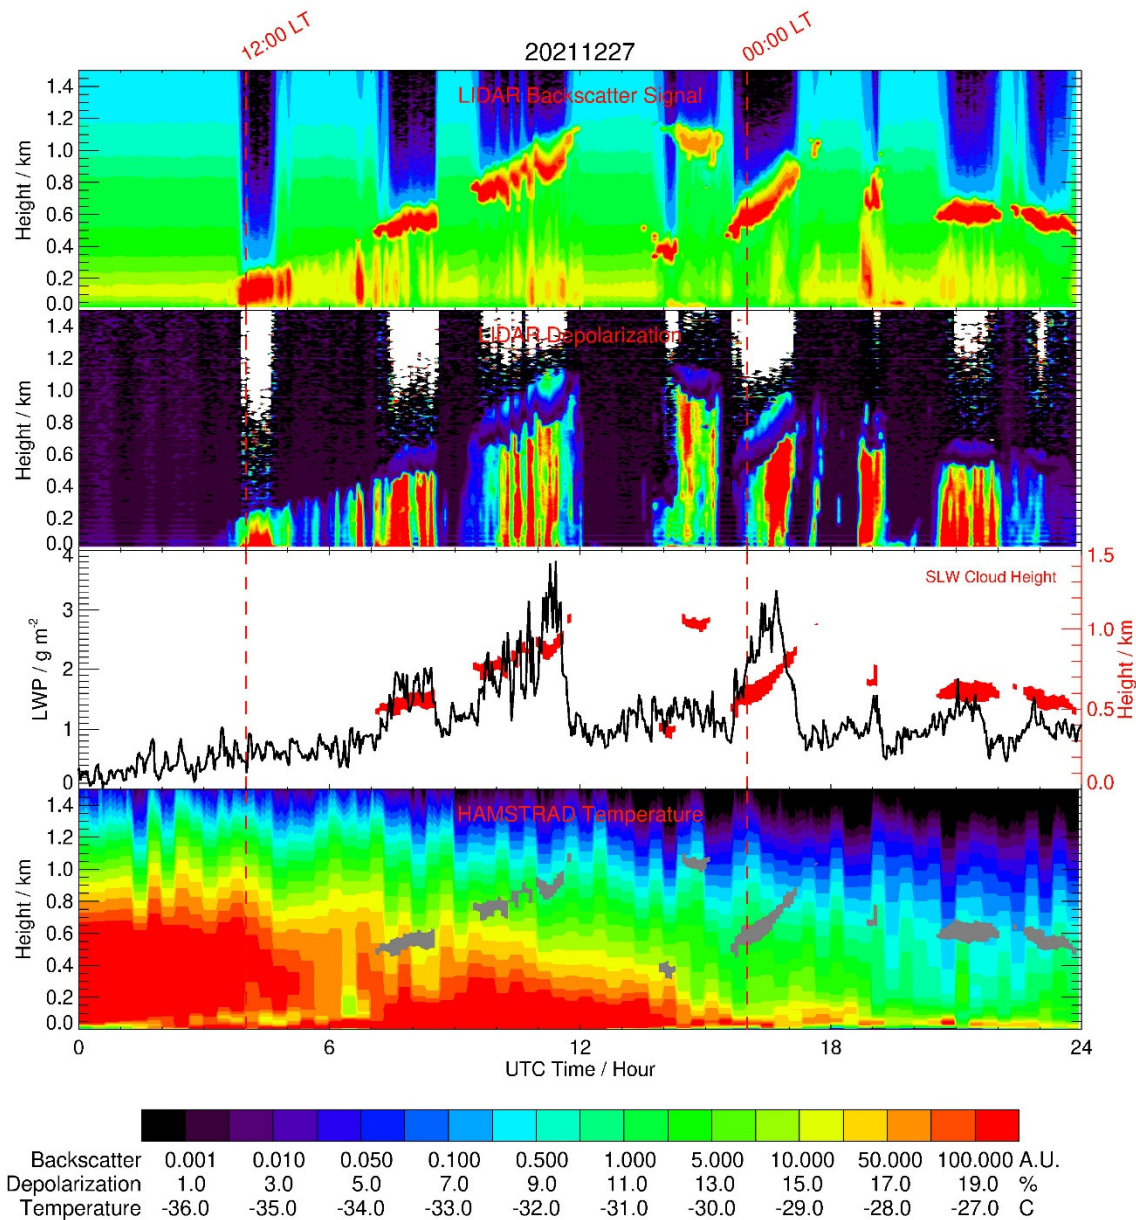

814 **Table 3.** Coefficients of the relations  $f(LWP) = \alpha + \beta \ln(LWP)$  for the temperature  $T$  or  
815 cloud radiative forcing ( $\Delta F_{net}$ ) and the individual components ( $\Delta F_{LW}^{Down}$ ,  $\Delta F_{LW}^{Up}$ ,  $\Delta F_{SW}^{Down}$  and  
816  $\Delta F_{SW}^{Up}$ ). Units of  $T$  and  $\Delta F$ , as well as of their corresponding “ $\alpha$ ” values are in  $^{\circ}\text{C}$  and  $\text{W m}^{-2}$ ,  
817 respectively; units of  $\beta$  are in  $^{\circ}\text{C g}^{-1} \text{m}^2$  for  $T$  and in  $\text{W g}^{-1}$  for  $\Delta F$ ; units of LWP are in  $\text{g m}^{-2}$ .  
818 The last column shows the range of LWP values for which the relation is valid.  $\alpha \pm \delta\alpha$   
819 corresponds to the range of  $\alpha$  values where the relationship is valid.

$f(LWP)$	$\alpha \pm \delta\alpha$	$\beta$	Valid range for $T$ or $\Delta F$	Valid range for LWP
$T$	$-33.8 \pm 1.5$	6.5	$[-36; -16]$	$[1.0; 14.0]$
$\Delta F_{net}$	$-18.0 \pm 10.0$	70.0	$[0; 70]$	$[1.2; 3.5]$
$\Delta F_{LW}^{Down}$	$5.0 \pm 15.0$	65.0	$[0; 90]$	$[1.0; 3.5]$
$\Delta F_{LW}^{Up}$	$0 \pm 5.0$	0.0	$[-5; 5]$	$[0.0; 6.5]$
$\Delta F_{SW}^{Down}$	$30.0 \pm 30.0$	-130.0	$[-130; 0]$	$[1.5; 4.0]$
$\Delta F_{SW}^{Up}$	$30.0 \pm 30.0$	-110.0	$[-110; 00]$	$[1.5; 4.0]$

820

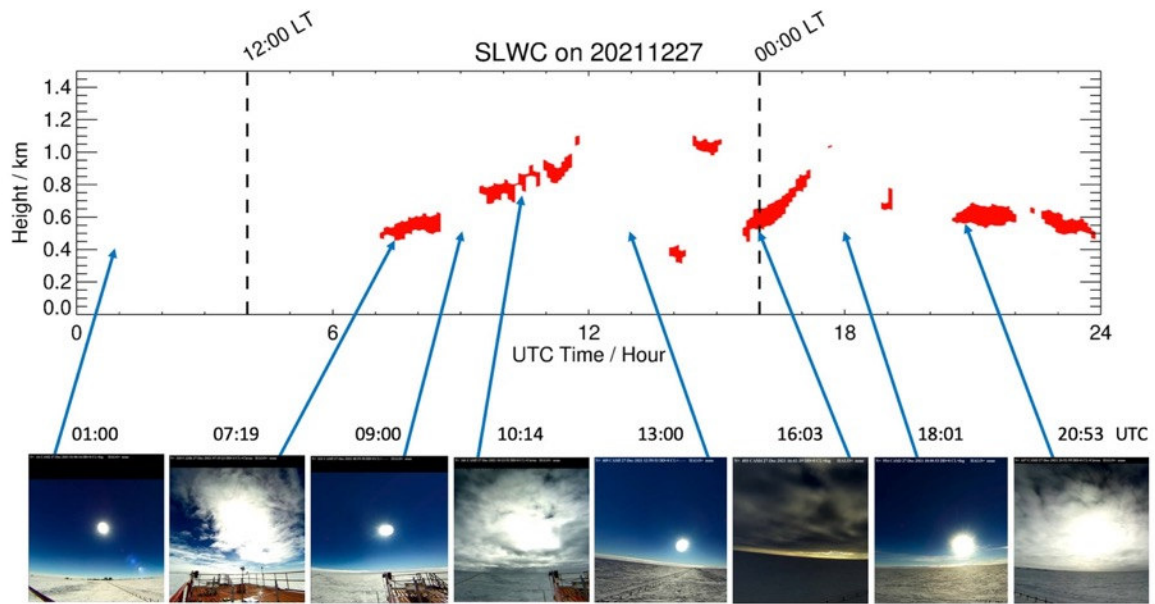

821

822

824

825 **Figure 1:** (From top to bottom): Time evolution (UTC, hour) of the LIDAR backscattering  
 826 signal, the LIDAR depolarization signal, the HAMSTRAD LWP and the HAMSTRAD  
 827 temperature profile measured on 27 December 2021. The time evolution of the SLW cloud (as  
 828 diagnosed by a backscattering value  $> 60$  A.U. and a depolarization value  $< 5\%$ ) is highlighted  
 829 by the red and grey areas in the third and the fourth panel from the top, respectively. The height  
 830 above the ground is shown on the third panel from the top with the y-axis on the right. The  
 831 00:00 and 12:00 local times (LT) are highlighted by 2 vertical dashed lines.

832

833 **Figure 2:** (Top) Time evolution (UTC, hour) of the SLWC (red areas) on 27 December 2021.

834 (Bottom, from left to right) Snapshots from the HALO-CAM video camera taken on: 01:00 (no

835 SLWC), 07:19 (SLWC), 09:00 (no SLWC), 10:14 (SLWC), 13:00 (no SLWC), 16:03 (SLWC),

836 18:01 (no SLWC) and 20:53 UTC (SLWC). The 00:00 and 12:00 local times (LT) are

837 highlighted by 2 vertical dashed lines.

838

839

840

841 **Figure 3:** (from top to bottom) Time evolution (UTC, hour) of the cloud radiative forcing

842 ( $\Delta F_{net}$ ) ( $\text{W m}^{-2}$ ) and its individual components: downward longwave ( $\Delta F_{LW}^{Down}$ ), upward

843 longwave ( $\Delta F_{LW}^{Up}$ ), downward shortwave ( $\Delta F_{SW}^{Down}$ ) and upward shortwave ( $\Delta F_{SW}^{Up}$ ) calculated

844 on 27 December 2021. The SLW cloud layer (if present) is highlighted by a red area in the

845 uppermost panel, with the height on the y-axis shown on the right. The 00:00 and 12:00 local

846 times (LT) are highlighted by 2 vertical blue dashed lines.

847

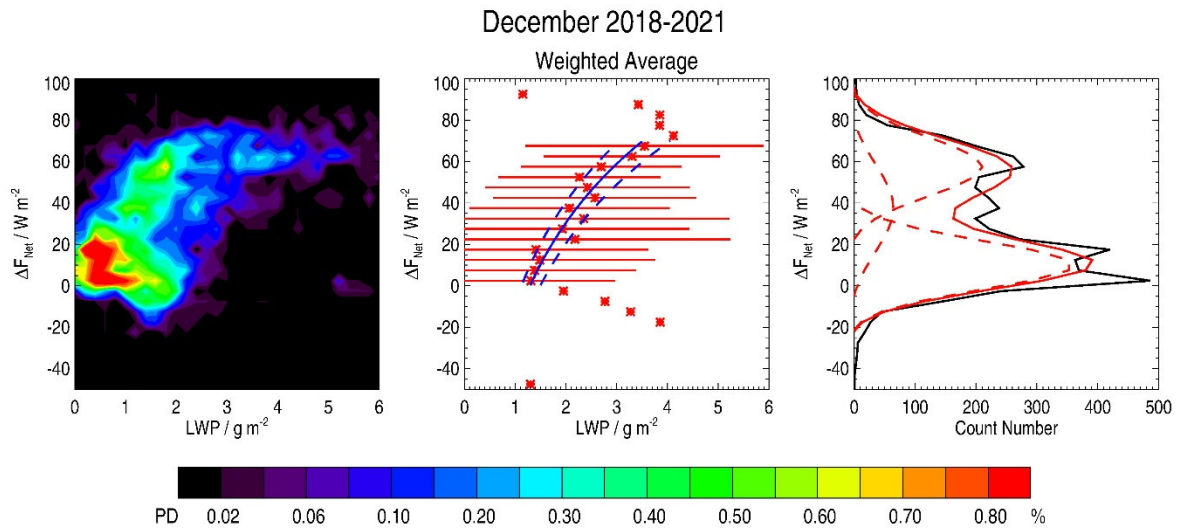

848

849 **Figure 4:** (Left) Probability Density (PD, %) of the temperature ( $^{\circ}\text{C}$ ) as a function of Liquid  
 850 Water Path (LWP,  $\text{g m}^{-2}$ ) in the SLWCs in December 2018-2021. The Probability Density is  
 851 defined in the text. (Centre) Weighted-average LWP vs. temperature (red asterisks) with a fitted  
 852 logarithmic function (blue solid) encompassing the significant points (within the two dashed  
 853 blue lines). Horizontal bars represent 1-sigma variability in LWP per  $1^{\circ}\text{C}$ -wide bin. (Right)  
 854 Temperature as a function of count number per  $1^{\circ}\text{C}$ -wide bin (black solid line) fitted with three  
 855 Gaussian functions (red dashed curves). The sum of the three Gaussian functions is represented  
 856 by a red solid line.

857

858

859

860 **Figure 5:** (Left) Probability Density (PD, %) of the cloud radiative forcing ( $\Delta F_{net}$ ,  $W m^{-2}$ ) as a  
 861 function of Liquid Water Path (LWP,  $g m^{-2}$ ) in the SLWCs in December 2018-2021. The  
 862 Probability Density is defined in the text. (Centre) Weighted-average LWP vs.  $\Delta F_{net}$  with a  
 863 fitted logarithmic function (blue solid) encompassing the significant points (within the two  
 864 dashed blue lines). Horizontal bars represent 1-sigma variability in LWP per  $5 W m^{-2}$ -wide bin.  
 865 (Right)  $\Delta F_{net}$  as a function of count number per  $5 W m^{-2}$ -wide bin (black solid line) fitted with  
 866 three Gaussian functions (red dashed curves). The sum of the three Gaussian functions is  
 867 represented by a red solid line.
