47 **Abstract**

48 Light absorbing organic carbon, or brown carbon (BrC), can be a significant contributor  
49 to the visible light absorption budget. However, the sources of BrC and the contributions of BrC  
50 to light absorption are not well understood. Biomass burning is thought to be a major source of  
51 BrC. Therefore, as part of the WE-CAN (Western Wildfire Experiment for Cloud Chemistry,  
52 Aerosol Absorption and Nitrogen) Study BrC absorption data was collected aboard the  
53 NSF/NCAR C-130 aircraft as it intercepted smoke from wildfires in the Western U.S. in July-  
54 August 2018. BrC absorption measurements were obtained in near real-time using two  
55 techniques. The first coupled a Particle-into-Liquid Sampler (PILS) with a Liquid Waveguide  
56 Capillary Cell and a Total Organic Carbon analyzer for measurements of water-soluble BrC  
57 absorption and WSOC (water-soluble organic carbon). The second employed a custom-built  
58 Photoacoustic Aerosol Absorption Spectrometer (PAS) to measure total absorption at 405 and  
59 660 nm. The PAS BrC absorption at 405 nm (PAS total Abs 405 BrC) was calculated by  
60 assuming the absorption determined by the PAS at 660 nm was equivalent to the black carbon  
61 (BC) absorption and the BC aerosol absorption Ångström exponent was 1. Data from the PILS  
62 and PAS were combined to investigate the water-soluble vs. total BrC absorption at 405 nm in  
63 the various wildfire plumes sampled during WE-CAN. WSOC, PILS water-soluble Abs 405,  
64 and PAS total Abs 405 tracked each other in and out of the smoke plumes. BrC absorption was  
65 correlated with WSOC ( $R^2$  value for PAS = 0.42 and PILS = 0.60) and CO (carbon monoxide)  
66 ( $R^2$  value for PAS = 0.76 and PILS = 0.55) for all wildfires sampled. The PILS water-soluble  
67 Abs 405 was corrected for the non-water-soluble fraction of the aerosol using the calculated  
68 UHSAS (Ultra-High-Sensitivity Aerosol Spectrometer) aerosol mass. The corrected PILS water-  
69 soluble Abs 405 showed good closure with the PAS total Abs 405 BrC with a factor of ~1.5 to 2  
70 difference. This difference was explained by particle vs. bulk solution absorption measured by  
71 the PAS vs. PILS, respectively, and confirmed by Mie Theory calculations. During WE-CAN,  
72 ~45% (ranging from 31% to 65%) of the BrC absorption was observed to be due to water-soluble  
73 species. The ratio of BrC absorption to WSOC or  $\Delta$ CO showed no clear dependence on fire  
74 dynamics or the time since emission over 9 h.

93     **1. Introduction**

94       Organic compounds can comprise a large fraction of PM (particulate matter) mass  
95 [Kanakidou *et al.*, 2005; Zhang *et al.*, 2007]. Organic carbon can be directly emitted or formed  
96 in the atmosphere from a variety of sources. This leads to organic aerosol particles composed of  
97 a number of compounds that range from insoluble to highly water-soluble and that can scatter or  
98 absorb light [Jacobson *et al.*, 2000; Saxena and Hildemann, 1996, and references therein].

99       The portion of organic carbon that is light-absorbing has been referred to as brown  
100 carbon (BrC) due to its yellow or brown color when concentrated, and it is likely to be a  
101 significant contributor to the visible light-absorption budget [Andreae and Gelencsér, 2006].  
102 Recent modeling studies have predicted a non-negligible effect on the Earth's radiation balance  
103 from BrC [Feng *et al.*, 2013; Zhang *et al.*, 2017; Zhang *et al.*, 2020]. Global measurements have  
104 shown that BrC can contribute up to 48% of the overall warming effect by absorbing  
105 carbonaceous aerosols [Zeng *et al.*, 2020]. BrC may also suppress photolysis rates of some  
106 chemical reactions, including decreasing surface ozone concentrations in certain locations, due to  
107 its ability to absorb at ultraviolet wavelengths [Jo *et al.*, 2016]. Some portion of BrC is likely  
108 composed of toxins, such as nitro- and oxy-aromatic species, suggesting BrC could also have  
109 health impacts [Desyaterik *et al.*, 2013; Verma *et al.*, 2015; Zhang *et al.*, 2013]. BrC itself is  
110 thought to have both primary and secondary sources. Particles from biomass burning or  
111 incomplete combustion of fossil fuels generally contain significant amounts of BrC (e.g.,  
112 [Chakrabarty *et al.*, 2010; Hoffer *et al.*, 2006; Kirchstetter *et al.*, 2004; Kirchstetter and  
113 Thatcher, 2012; Lack *et al.*, 2012; Lukács *et al.*, 2007]). Laboratory studies have observed  
114 production of BrC from a number of formation processes. This has included heterogenous  
115 reactions of isoprene on acidic aerosol particles, a variety of aqueous-phase reactions, and  
116 reactions of organic compounds in acidic solutions (e.g., [Hoffer *et al.*, 2006; Limbeck *et al.*,  
117 2013; Sareen *et al.*, 2010; Updyke *et al.*, 2012]). However, there is still limited information on  
118 the contribution of BrC to total light absorption and the sources of BrC as there are few ambient  
119 measurements.

120       Total absorption measurements (black carbon (BC) + BrC) at multiple wavelengths can  
121 be used to determined BrC absorption due to the strong wavelength dependence of BrC. This  
122 requires the assumptions that: (1) the absorption Ångström exponent (AAE) for BC is known, (2)  
123 AAE is constant with wavelength, and (3) BrC does not absorb at longer wavelengths. The AAE  
124 for BC is well constrained at 1 in the visible and near-infrared wavelengths [Moosmüller *et al.*,  
125 2009]. The BrC absorption at other wavelengths is then found by difference from the  
126 extrapolated BC AAE [Lack and Langridge, 2013; Mohr *et al.*, 2013]. This approach can be  
127 applied to any technique that measures absorption at multiple wavelengths, including  
128 photoacoustic spectroscopy (PAS).

129       BrC can also be quantified by isolating the BrC chromophores by extraction of particles  
130 in solvents, such as water or methanol, in order to separate them from the insoluble BC and then  
131 measuring the light absorption of the soluble organic chromophores [Hecobian *et al.*, 2010].  
132 This is the only direct method to separate and quantify BrC as the light absorption from liquid  
133 extracts does not suffer from interferences by BC as they can be isolated by dissolution. A  
134 spectrophotometer with an UV/Vis (ultraviolet/visible) light source can provide high spectral  
135 resolution over a wide wavelength range from 200 to 800 nm. In addition, when coupled with a  
136 long-path liquid waveguide capillary absorption cell (LWCC), it also provides a highly sensitive  
137 measurement. This technique can be used off-line with filters or on-line with an aerosol

138 collection device such as Particle-into-Liquid Sampler (PILS) (e.g., [Hecobian *et al.*, 2010; Liu  
139 *et al.*, 2013, 2014, 2015; Zhang *et al.*, 2011, 2013].

140 Here we report BrC absorption data from a PAS and PILS-LWCC-TOC system to  
141 compare total vs. water-soluble BrC absorption in wildfire smoke. Data are from smoke plume  
142 penetrations during the Western Wildfire Experiment for Cloud Chemistry, Aerosol Absorption  
143 and Nitrogen (WE-CAN), an aircraft-based study focused on investigating the chemistry and  
144 transformation of emissions from wildfires in the western U.S. We examine the relationship  
145 between the BrC absorption and species known to be from biomass burning. We discuss how  
146 parameters such as aging and fire dynamics might influence BrC absorption from wildfires.

## 147 2. Methods

### 149 2.1. The Airborne Mission

150 The WE-CAN Campaign was a multi-investigator study conducted aboard the National  
151 Science Foundation/National Center for Atmospheric Research (NSF/NCAR) C-130 aircraft.  
152 The C-130 was operated out of Boise, ID from Jul. 20 to Aug. 31, 2018. A suite of instruments  
153 was deployed for measurements of aerosol and trace gas composition. A total of 16 research  
154 flights sampled wildfire smoke over the western U.S. to characterize emissions, mixing,  
155 chemical transformations, and transport. Figure 1 presents a map of the flight transects and  
156 locations of the wildfires sampled. (We exclude Flight RF14, which was conducted off the coast  
157 of CA to sample a stratus deck impacted by smoke, and Flight RF16, which consisted of an  
158 intercomparison performed near Boise between WE-CAN and BB-FLUX (Biomass Burning  
159 Flux Measurements of Trace Gases and Aerosols) common measurements.) More information  
160 on each wildfire including the type of fuel consumed is available in the WE-CAN Field Catalog  
161 (catalog.eol.ucar.edu/we-can). WE-CAN sampled both fresh and aged (for Flights RF05 and  
162 RF08 along with parts of Flights RF07 and RF13) emissions from smoke for wildfires burning in  
163 CA, OR, WA, ID, MT, UT, and NV. The general sampling strategy was to circle the wildfire at  
164 the source and then follow the smoke downwind using a multiple transect search and rescue  
165 pattern to examine smoke evolution. Typically, wildfire smoke plumes were sampled in the free  
166 troposphere between 3-5 km during early afternoon to evening periods (20:00 to 02:00 UTC or  
167 14:00 to 20:00 LT). Flight RF08 and part of Flight RF07 were exceptions as the aircraft sampled  
168 the boundary layer (below 2 km) over the Central Valley of CA.

### 170 2.2. Particle Collection

171 During WE-CAN, we deployed two Particle-into-Liquid Sampler (PILS) systems. A  
172 PILS is an aerosol collection device that continuously collects ambient particles into purified  
173 water [Orsini *et al.*, 2003]. After particles are grown inside the body of the PILS by water  
174 condensation in a supersaturated water vapor environment, formed through mixing the ambient  
175 air sample with saturated air (100% relative humidity) at higher temperature, the particles are  
176 collected by an impactor. The impactor plate is continually washed off by a flow of liquid  
177 passed over the impactor, providing a liquid sample containing dissolved aerosol particles which  
178 can be analyzed by various methods. Each PILS system sampled from their own Submicron  
179 Aerosol Inlet (SMAI) [Craig *et al.*, 2013a, 2013b, 2014; Moharreri *et al.*, 2014] mounted to the  
180 belly of the NSF/NCAR C-130. The size-cut for each PILS was provided by a nonrotating  
181 MOUDI impactor stage with a 50% transmission efficiency of 1  $\mu\text{m}$  aerodynamic diameter (i.e.,  
182  $\text{PM}_1$ ) at 1 atmosphere ambient pressure [Marple *et al.*, 1991]. The flowrate of 15 LPM was  
183 sampled by each PILS through the inlet and MOUDI stage. An activated carbon parallel plate

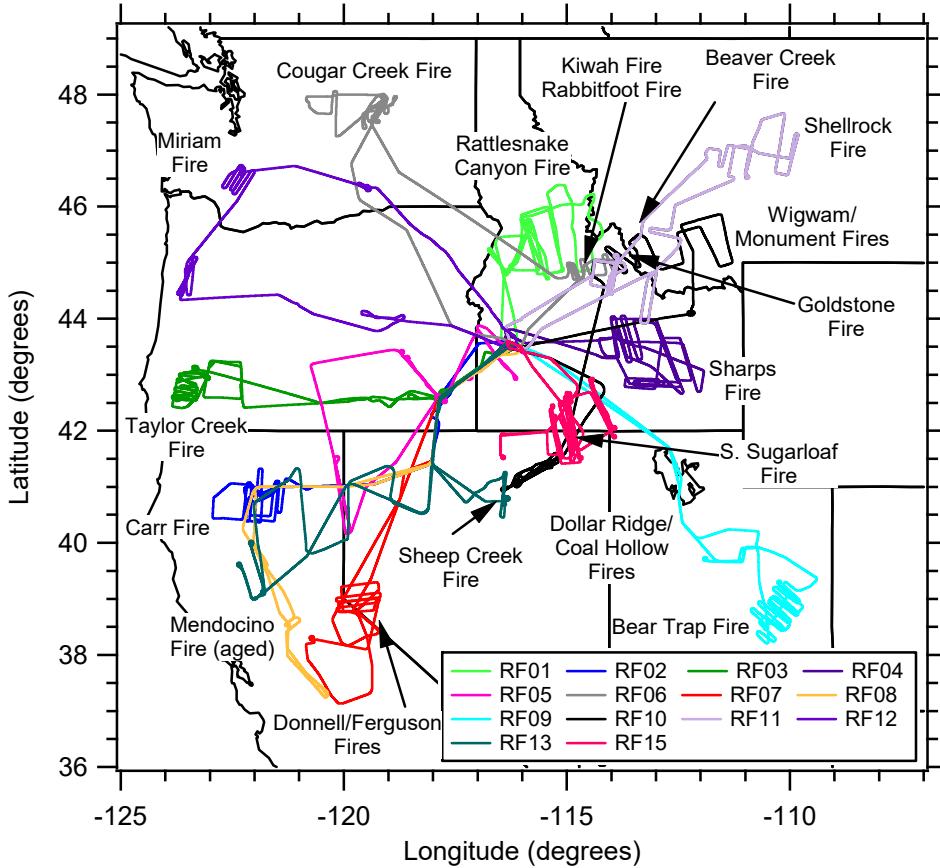

Figure 1. Map showing the flight paths and locations of the wildfires sampled during WE-CAN used in this analysis.

denuder [Though *et al.*, 1993] was situated upstream of both PILS to remove organic gases. In addition, for PILS2 two honeycomb denuders coated with sodium carbonate and phosphorous acid were used to remove inorganic acidic and basic gases in order to limit possible positive artifacts from dissolving in the PILS collection liquid. PILS 1 was connected to a LWCC (liquid waveguide capillary cell) and TOC (Total Organic Carbon) Analyzer for near real-time measurement of water-soluble BrC (Brown Carbon) absorption and WSOC (water-soluble organic carbon), respectively. PILS2 was coupled to a Bretschel fraction collector system [Sorooshian *et al.*, 2006] to provide liquid samples for additional off-line analysis.

For PILS 1, a valve upstream of the PILS was manually closed periodically for 10 min forcing the airflow through a Teflon filter allowing for a measurement of the background in near real-time. The liquid sample obtained from PILS1 was then pushed through a  $0.2 \mu\text{m}$  PTFE liquid filter at a flowrate of  $1.2 \text{ mL/min}$  by a set of syringe pumps with  $1 \text{ mL}$  syringes to ensure any insoluble particles were removed before passing through the LWCC and TOC Analyzer.

A LWCC with a  $2.5 \text{ m}$  path-length (World Precision Instruments, Sarasota, FL) was employed. An absorption spectrometer (FLAME-T-UV-VIS, Ocean Optics, Largo, FL) and dual deuterium and tungsten halogen light source (DH-mini, Ocean Optics, Largo, FL) were coupled to the LWCC via fiber optic cables. The Oceanview Spectroscopy Software was used to record

204 absorption spectra over a range from 200 to 800 nm. In this paper we present the absorption  
205 determined at 365 and 405 nm. This wavelength dependent absorption was calculated following  
206 the method outlined in *Hecobian et al.* [2010]. A 16 s integrated measurement of water-soluble  
207 absorption with a limit of detection (LOD) of  $0.1 \text{ Mm}^{-1}$  was obtained.

208 A Sievers Model M9 Portable TOC Analyzer (Suez Waters Analytical Instruments,  
209 Boulder, CO) was used for the WSOC measurement. This analyzer converts organic carbon in  
210 the liquid sample to carbon dioxide using chemical oxidation with ammonium persulfate and  
211 ultraviolet light. The carbon dioxide formed is then measured by conductivity. The amount of  
212 OC present in the sample is proportional to the increase in conductivity observed. The analyzer  
213 was run in turbo mode providing a 4 s integrated measurement of WSOC with a LOD of  $0.1 \mu\text{g}$   
214  $\text{C/m}^3$ .

215 For PILS2, a valve upstream of the PILS was manually closed periodically for 10 min  
216 forcing the airflow through a hepa filter allowing for measurement of the background in near  
217 real-time. The liquid sample obtained from PILS2 was pushed into the fraction collector vials at  
218 a flowrate of 0.65 mL/min by a peristaltic pump for collection of  $\sim 1.2 \text{ mL}$  of liquid sample per  
219 vial. Each fraction collector carousel holds 72 1.5 mL polypropylene vials (Microsolv  
220 Technology Corporation, Leland, NC). Vials were fitted with pre-slit caps and used as supplied.  
221 The fraction collector program was set to allow continuous collection of 2 min integrated  
222 samples and was manually started after take-off. Carousels were pre-loaded before flight and  
223 then manually switched out as they were filled. The vials were unloaded from the carousels at  
224 the end of each flight, recapped with solid caps (Microsolv Technology Corporation), packed in  
225 coolers with ice packs, and shipped back to Colorado State University to be stored in a  $2^\circ\text{C}$  cold  
226 room until analysis began following completion of the study.  
227

### 228 **2.3. Off-line Analysis**

229 Each fraction collector vial was brought to room temperature and then analyzed for  
230 anhydrosugars as well as cations. For each analysis,  $300 \mu\text{L}$  aliquots were transferred to  
231 polypropylene vials. Only levoglucosan, water-soluble potassium, and ammonium are discussed  
232 here and their analytical methods are explained below.

233 The levoglucosan analysis was performed on a Dionex DX-500 series ion chromatograph  
234 with pulsed amperometric detection via an ED-50/ED-50A electrochemical cell. This cell  
235 includes two electrodes: a “standard” gold working electrode and pH-Ag/AgCl (silver/silver  
236 chloride) reference electrode. A sodium hydroxide gradient and a Dionex CarboPac PA-1  
237 column (4 x 250 mm) were employed for the separation. The complete run time was 59 min  
238 with an injection volume of  $100 \mu\text{L}$ . More details on the method can be found in *Sullivan et al.*  
239 [2011a,b, 2014, 2019]. Only levoglucosan could be detected in the WE-CAN samples (other less  
240 abundant anhydrosugars were too low to detect in the PILS samples) and did not require  
241 background correction. The LOD for levoglucosan based on a sample collection time of 2 min  
242 and air flowrate of 15 LPM was determined to be less than approximately  $0.10 \text{ ng/m}^3$ .

243 A Dionex ICS-3000 ion chromatograph equipped with a conductivity detector was used  
244 to measure water-soluble potassium and ammonium. An eluent generator provided a  
245 concentration of 20 mM methanesulfonic acid at a flowrate of  $0.5 \text{ mL/min}$  to perform the  
246 separation on a Dionex IonPac CS12A analytical column (3 x 150 mm). The complete run time  
247 was 17 min with an injection volume of  $190 \mu\text{L}$ . A blank correction was necessary for both of  
248 these species unlike levoglucosan. Therefore, their concentrations were corrected by using the

249 average of all background samples collected during a specific flight. For water-soluble  
250 potassium and ammonium, the LOD was 1 ng/m<sup>3</sup>.  
251

## 252 **2.4. Photoacoustic Aerosol Absorption Spectrometer**

253 A custom-built PAS was used to measure total aerosol absorption at 405 and 660 nm  
254 [Foster *et al.*, 2019] every 1 s during WE-CAN. The PAS measures aerosol light absorption at  
255 near-ambient conditions by heating particles using a controlled light source and detecting the  
256 resulting soundwave. It can be subject to interference by gaseous absorbers and is sensitive to  
257 variations in relative humidity, temperature, and pressure [Arnott *et al.*, 1999; Langridge *et al.*,  
258 2013]. The PAS sampled from a Solid Diffuser Inlet (SDI) mounted on the front right side of the  
259 NSF/NCAR C-130. Aerosol passed through a cyclone impactor before entering the PAS to  
260 remove particles with aerodynamic diameters > 1  $\mu\text{m}$ . The flowrate for the PAS was 4 LPM.  
261 Upstream of the PAS was a denuder to remove NO<sub>x</sub> (nitrogen oxides) from the sample air as  
262 well as a Perma Pure dryer to dry the aerosol to below 30% relative humidity. A filter was  
263 periodically switched in-line before the PAS to remove particles and allow for a near real-time  
264 measurement of the baseline stability. Additionally, the PAS switched between sampling with  
265 and without a thermal denuder system in-line. Only the data from sampling without the thermal  
266 denuder is presented here. The PAS BrC absorption at 405 nm (PAS total Abs 405 BrC) was  
267 calculated using equation 9 from Pokhrel *et al.* [2017]. This approach assumes the absorption  
268 determined by the PAS at 660 nm was equivalent to BC absorption, the BC aerosol AAE was 1,  
269 and the absorption enhancement from lensing was constant at all wavelengths. Previous work  
270 using this approach in smoke from controlled laboratory burns found lensing could contribute a  
271 maximum of 30% of total absorption, but typical contributes much less.  
272

## 273 **2.5. Ultra-High-Sensitivity Aerosol Spectrometer**

274 One second particle number concentrations were measured using a rack-mounted  
275 UHSAS (Ultra-High-Sensitivity Aerosol Spectrometer). The rack-mounted UHSAS switched  
276 between sampling from the SDI inlet and a CVI (counter-flow virtual impactor) when sampling  
277 out of and in-cloud, respectively. We only present data for sampling out of clouds. The rack-  
278 mounted UHSAS was operated so that the flow could be manually lowered by the in-flight  
279 operator when the NSF/NCAR C-130 flew through smoke plumes to allow the UHSAS to stay  
280 within its optimum concentration measurement range. The UHSAS measures particles in the  
281 0.06-1  $\mu\text{m}$  range. The particle size bins for the UHSAS were calibrated using ammonium sulfate  
282 rather than traditional PSL (polystyrene latex) spheres. Particle mass concentrations for PM<sub>1</sub>  
283 were calculated by summing all size bins and then multiplying by 1.4 g/cm<sup>3</sup> to account for  
284 particle density.  
285

## 286 **2.6. Other Measurements**

287 In the following analysis, we focus on characterizing the BrC absorption in smoke from  
288 wildfires in the western U.S. sampled during WE-CAN. Other airborne measurements used in  
289 this analysis include meteorological data and coordinates provided by the Research Aviation  
290 Facility (RAF) as part of the C-130 instrumentation package  
291 (<https://data.eol.ucar.edu/project/WE-CAN>) and one Hz carbon monoxide (CO) determined by a  
292 vacuum UV (ultraviolet) resonance fluorescence method [Gerbig *et al.*, 1999]. All data  
293 presented in our analysis are reported at 1 atm and 273 K. Data from all species have been  
294 averaged to match the 2 min collection time of the PILS-fraction collector system.

301

## 2.7. Mie Calculation

Mie calculations were performed by putting the complex refractive index ( $m = n + ik$ ) into Mie code to obtain the absorption efficiency ( $Q$ ) and then further calculate the absorption coefficient using Eq. 1 [Liu *et al.*, 2013]. The real part of the refractive index ( $n$ ) was set to be 1.55 and the imaginary part was calculated using Eq. 2 [Liu *et al.*, 2013].

303

$$302 \quad \beta(\lambda, D_p) = \frac{3}{2} \cdot \frac{Q \cdot WSOC}{D_p \cdot \rho} \quad (Eq. 1)$$

303

$$304 \quad k = \frac{\rho \lambda \cdot H_2O\beta(\lambda)}{4\pi \cdot WSOC} \quad (Eq. 2)$$

305

In Eq. 1 and 2,  $\lambda$  is the wavelength,  $D_p$  is the diameter of the particle,  $\beta$  is the absorption coefficient (referred to as the Mie calculated water-soluble absorption hereinafter),  $Q$  is the absorption efficiency,  $WSOC$  is the water-soluble organic carbon mass concentration measured by the PILS, and  $H_2O\beta(\lambda)$  is the water-soluble light absorption coefficient measured by the PILS. The particle density ( $\rho$ ) was assumed to be 1.4 g/cm<sup>3</sup>. The plume averaged particle size distribution (measured by the UHSAS) was used in the calculation. The Mie calculated water-soluble absorption was determined for each size bin in order to obtain the most accurate results. Mie calculated total absorption was further calculated by multiplying the Mie calculated water-soluble absorption by (UHSAS mass)/(WSOC\*1.6), where the factor of 1.6 was to convert WSOC to WSOM (water-soluble organic matter) [Duarte *et al.*, 2019; Yttri *et al.*, 2007].

316

## 3. Results and Discussion

317  
318

### 3.1. Overview

319

Most previous studies employing a LWCC to determine water-soluble absorption, examine the absorption at 365 nm (e.g., [Hecobian *et al.*, 2010; Zhang *et al.*, 2011, 2013]). But here in order to explore the relationship between the water-soluble and total absorption determined by the PILS and PAS, respectively, we focus on the absorption at 405 nm determined by the LWCC. Using as examples Flight RF02, which sampled the Carr Fire smoke plume, and Flight RF11, which sampled the Goldstone, Rabbit Foot, Beaver Creek, and Shellrock Fire smoke plumes, Figures 2a and b show the relationship of the PILS water-soluble Abs 405 vs. Abs 365. Absorption values at these two wavelengths are correlated ( $R^2$  values from 0.70 to 1.00 based on all individual WE-CAN Flights), but the absorption measured at 405 nm was about half of that observed at 365 nm (slope average 0.45 and range from 0.39 to 0.52 across all individual WE-CAN flights). We selected these two flights to cover the range in the relationships observed during WE-CAN. The lower correlation for Flight RF11 is likely due to the narrower plumes being sampled compared to the broader plumes observed in Flight RF02. This difference related to narrow vs. broad plumes was observed throughout the various wildfires sampled during WE-CAN.

334  
335  
336

Figure 3 shows example time series for WSOC, PILS water-soluble Abs 405, and PAS total Abs 405 BrC from the same two flights as above. It was observed that all three parameters tracked each other in and out of the smoke plumes. During WE-CAN, the average value  $\pm$

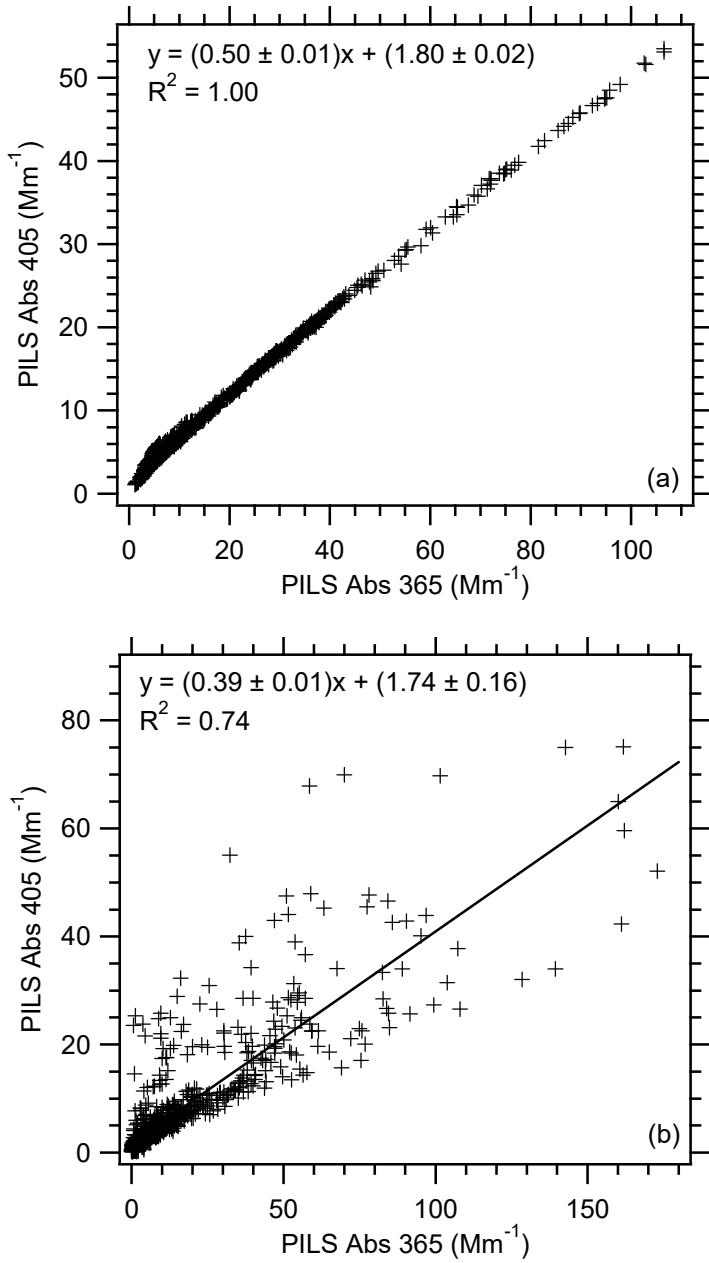

Figure 2. Correlation of PILS water-soluble Abs 405 vs. PILS water-soluble Abs 365 for WE-CAN (a) Flight RF02 and (b) Flight RF11. Uncertainties with the least square regressions are one standard deviation.

343

344 standard deviation for WSOC, PILS water-soluble Abs 405, and PAS total Abs 405 BrC were  
 345  $13.35 \pm 16.80 \mu\text{g C/m}^3$ ,  $6.06 \pm 6.88 \text{ Mm}^{-1}$ , and  $22.02 \pm 49.16 \text{ Mm}^{-1}$ , respectively. The water-  
 346 soluble absorption determined by the PILS was lower than the total absorption determined by the  
 347 PAS. This pattern was consistently observed for all the wildfires sampled throughout WE-CAN.  
 348

### 349 3.2. Relationship between Total and Water-Soluble BrC Absorption

350 To further explore the relationship between total and water-soluble BrC absorption, we  
 351 examine the relationship between PAS total Abs 405 BrC and UHSAS mass for Flights RF02  
 352 and RF11. There is a strong correlation between PAS total Abs 405 BrC and UHSAS mass

353 (Figure 4). Therefore, the PILS water-soluble Abs 405 can be corrected for the non-water-  
354 soluble fraction of the aerosol using the UHSAS mass. This was achieved by multiplying the  
355 PILS water-soluble Abs 405 by  $1/((\text{WSOC} \times 1.6) / (\text{UHSAS mass}))$  or  $(\text{UHSAS}$   
356  $\text{mass}) / (\text{WSOC} \times 1.6)$ . This approach assumes the characteristics of the non-water-soluble  
357 components of OC are identical to that of the water-soluble components of OC.

358 Correcting the PILS water-soluble Abs 405 by the UHSAS mass showed good closure  
359 with the PAS total Abs 405 BrC, but with a factor of  $\sim 1.5$  to 2 difference between the PILS  
360 water-soluble Abs 405 corrected and PAS total Abs 405 BrC (Figures 4c and d). This is also  
361 similar to results obtained from the sampling of wildfire smoke during the FIREX (Fire Influence  
362 on Regional and Global Environments Experiment) Campaign, where there was a ratio of 3.2  
363 between PAS Abs 405 BrC and water-soluble Abs 405 determined from off-line LWCC analysis  
364 of filter samples [Zeng *et al.*, 2020]. This factor difference in both the WE-CAN and FIREX  
365 data is likely due to the differences in particle vs. bulk solution absorption measured by the PAS  
366 vs. LWCC (using PILS or filter samples), respectively, and can be explained by Mie Theory.

367 We used Mie Theory to calculate the water-soluble and total particle Abs 405 (see section  
368 2.7 for details on the equations and parameters used) through each plume transect for RF02 and  
369 RF11. As shown in Figures 5a and b, we found a slope of 1.7 to 1.8 for Mie calculated water-  
370 soluble Abs 405 to PILS Abs 405 and 3 to 4 for Mie calculated total Abs 405 to PILS Abs 405.  
371 This is similar to results presented in Liu *et al.* [2013] and based on off-line LWCC analysis of  
372 filter samples collected at 3 sites in Georgia. In that work, a ratio of 2 for Mie calculated water-  
373 soluble Abs 365 to measured water-soluble Abs 365 and a ratio of 3.6 for Mie calculated total  
374 Abs 365 to measured water-soluble Abs 365 were observed. In Zeng *et al.* [2022], Mie Theory  
375 was used to calculate the factor to convert solution to particle light absorption (i.e., ratio of Mie  
376 calculated to measured water-soluble absorption) as a function of wavelength for the FIREX  
377 data. At 405 nm a factor of  $\sim 1.7$  was determined, similar to what was determined from the WE-  
378 CAN data.

379 As a further check on the calculations performed here, the PAS Abs 405 BrC was  
380 compared to the Mie calculated total Abs 405. Slopes ranged from 1.04 to 1.08 (Figures 5c and  
381 d). This suggested our approach for correcting the PILS water-soluble Abs 405 for the non-  
382 water-soluble fraction as well as to calculate the BrC absorption from the PAS Abs 405 data  
383 were valid.

384 Overall, during WE-CAN  $\sim 45\%$  (ranging from 31% to 65%) of the BrC absorption at  
385 Abs 405 was due to water-soluble species. This is similar to what was observed from off-line  
386 LWCC analysis of water and methanol extracts from filter samples collected during sampling of  
387 biomass burning plumes as part of the DC3 (Deep Convective Clouds and Chemistry),  
388 SEAC4RS (Studies of Emissions, Atmospheric Composition, Clouds and Climate Coupling by  
389 Regional Surveys), and FIREX aircraft campaigns [Forrister *et al.*, 2015; Liu *et al.*, 2015; Zeng  
390 *et al.*, 2022].

### 391 3.3. BrC Absorption, CO, WSOC, and Levoglucosan

392 Using data from all WE-CAN flights, Figure 6 shows that the PAS total Abs 405 BrC and  
393 PILS water-soluble Abs 405 are correlated with CO ( $R^2$  value for PAS = 0.76 and PILS = 0.55).  
394 This further illustrates the importance of biomass burning as a source of BrC absorption (e.g.,  
395 [Andreae and Gelencsér, 2006; Chakrabarty *et al.*, 2010; Duarte *et al.*, 2005; Hecobian *et al.*,  
396 2010; Hoffer *et al.*, 2006; Lack *et al.*, 2012; Lukács *et al.*, 2007]), especially since more than  
397 75% of the WE-CAN data occurred in smoke.

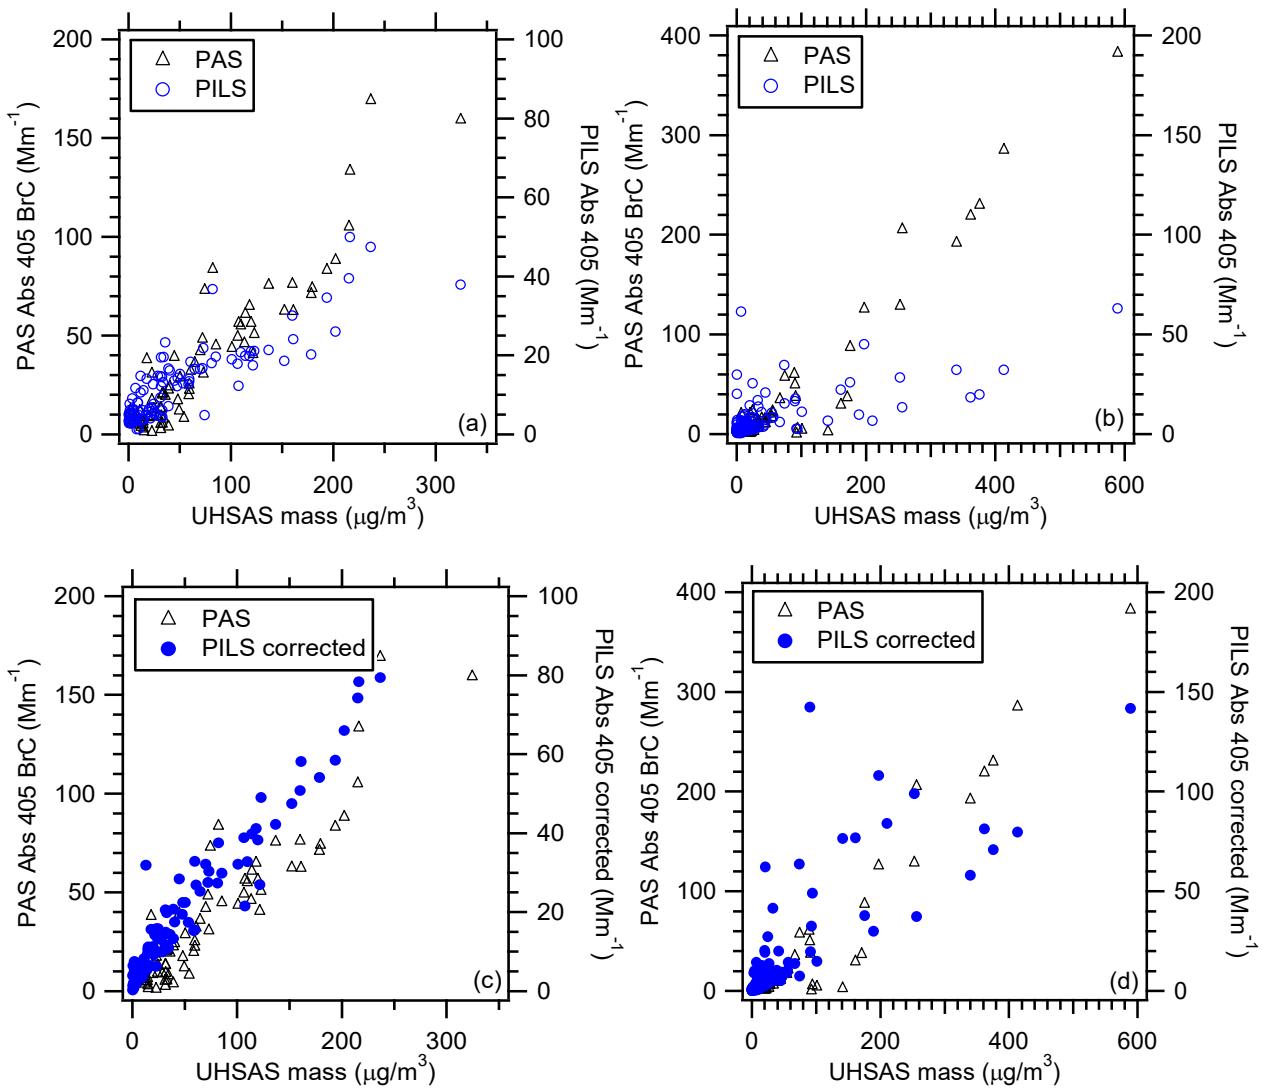

Figure 4. Correlation of PAS total Abs 405 BrC and PILS water-soluble Abs 405 vs. UHSAS mass for WE-CAN (a) Flight RF02 and (b) Flight RF11. Correlation of PAS total Abs 405 BrC and PILS water-soluble Abs 405 corrected for the non-water-soluble fraction of the aerosol using the UHSAS mass for WE-CAN (c) Flight RF02 and (d) Flight RF11. In plot (a), the equations for the fit and  $R^2$  value for PAS are  $y = (0.50 \pm 0.02)x - (0.03 \pm 2.29)$ ,  $R^2 = 0.87$  and for PILS are  $y = (0.14 \pm 0.01)x + (5.58 \pm 0.65)$ ,  $R^2 = 0.75$ , respectively. In plot (b), the equations for the fit and  $R^2$  value for PAS are  $y = (0.62 \pm 0.03)x - (6.09 \pm 3.62)$ ,  $R^2 = 0.76$  and for PILS are  $y = (0.08 \pm 0.01)x + (3.58 \pm 0.66)$ ,  $R^2 = 0.43$ , respectively. In plot (c), the equation for the fit and  $R^2$  value for PILS are  $y = (0.32 \pm 0.01)x + (3.60 \pm 0.68)$ ,  $R^2 = 0.94$ , respectively. In plot (d), the equation for the fit and  $R^2$  value for PILS are  $y = (0.24 \pm 0.01)x + (2.93 \pm 1.35)$ ,  $R^2 = 0.65$ , respectively. Uncertainties with the least square regressions are one standard deviation.

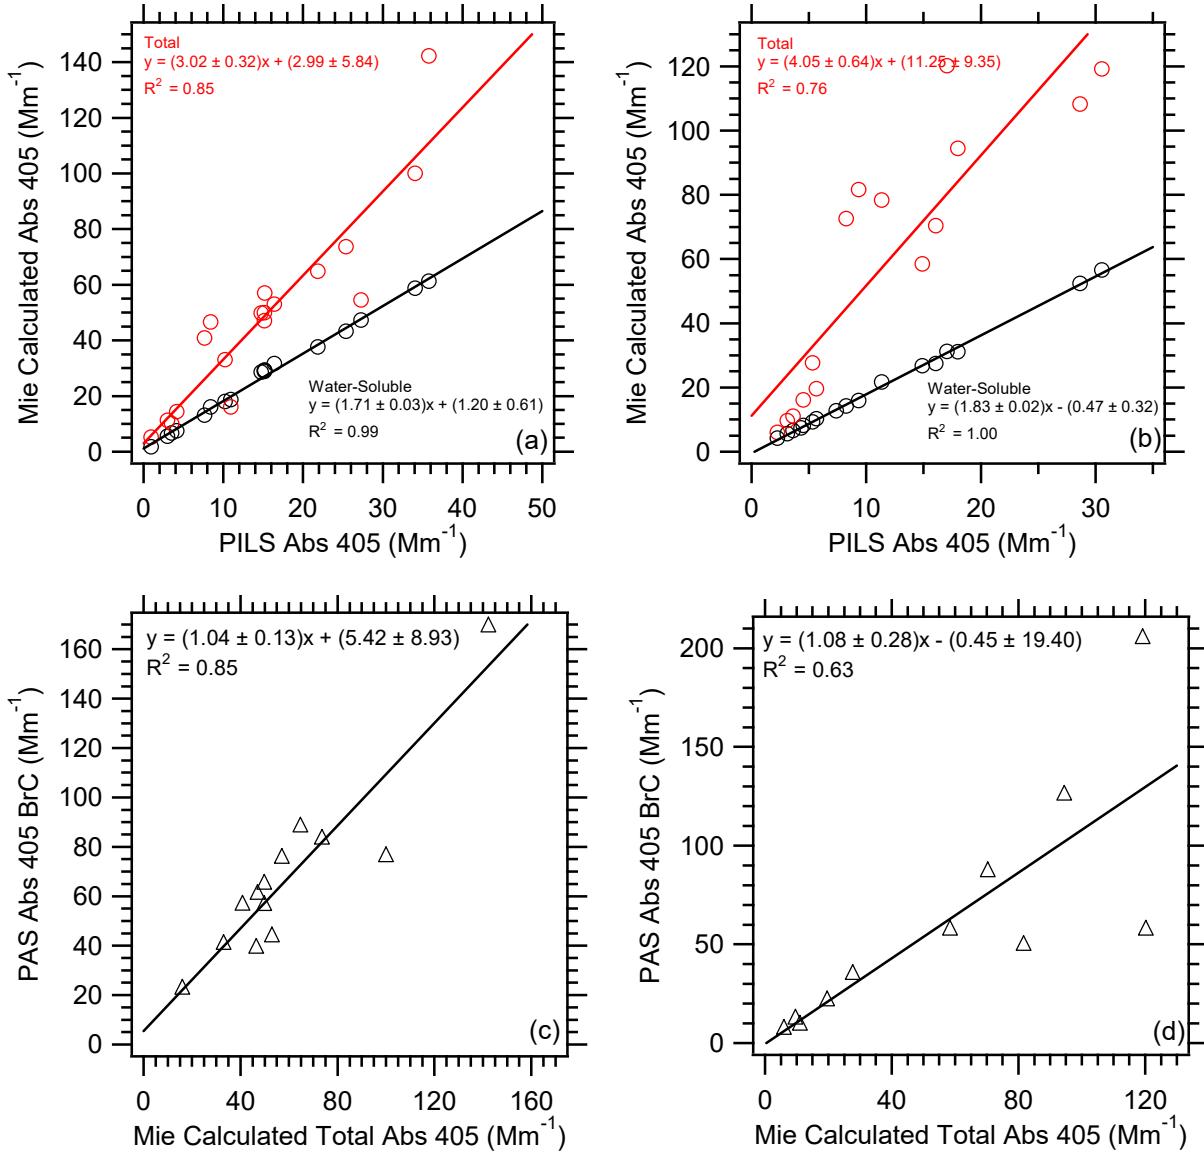

Figure 5. Correlation of Mie calculated water-soluble and total Abs 405 vs. PILS water-soluble Abs 405 for WE-CAN (a) Flight RF02 and (b) Flight RF11. Correlation of PAS total Abs 405 BrC and Mie calculated total Abs 405 for WE-CAN (c) Flight RF02 and (d) Flight RF11. Uncertainties with the least square regressions are one standard deviation.

403  
 404  
 405  
 406 Figure 7 shows that there is a correlation between BrC absorption and WSOC ( $R^2$  value  
 407 for PAS = 0.42 and PILS = 0.60). This is not surprising given that the two main sources of  
 408 WSOC are typically biomass burning and secondary organic aerosol (SOA) [Sullivan *et al.*,  
 409 2006]. A number of previous studies where the source of WSOC and Abs 365 was one or both  
 410 of these have observed a similar correlation (e.g., [Hecobian *et al.*, 2010; Liu *et al.*, 2015; Zhang  
 411 *et al.*, 2013]).  
 412

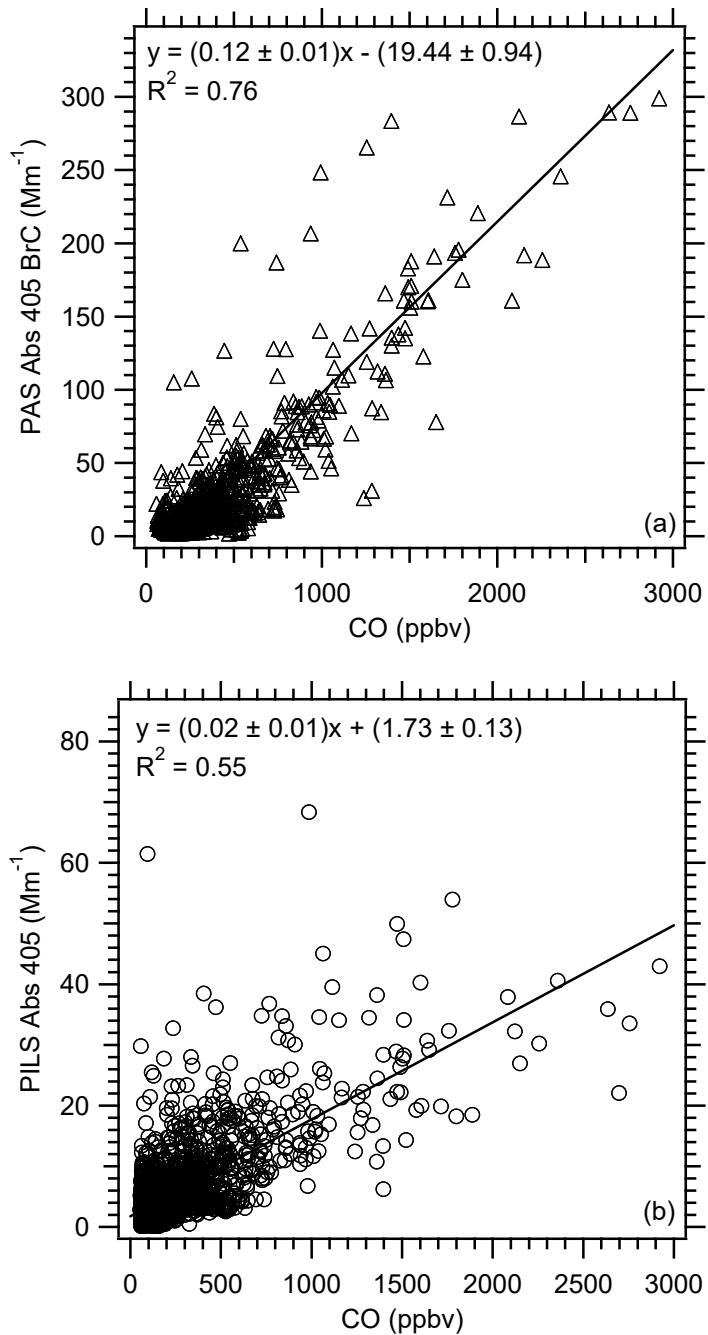

Figure 6. Correlation of (a) PAS total Abs 405 BrC and (b) PILS water-soluble Abs 405 vs. CO for all WE-CAN flights used in this analysis. Uncertainties with the least square regressions are one standard deviation.

413  
414  
415  
416  
417  
418

BrC absorption has a similar relationship with CO and WSOC as the biomass burning marker levoglucosan [Simoneit *et al.*, 1999], but there are additional features (Figure 8). There is some variability in the ratio of levoglucosan to the PAS total Abs 405 BrC and PILS water-

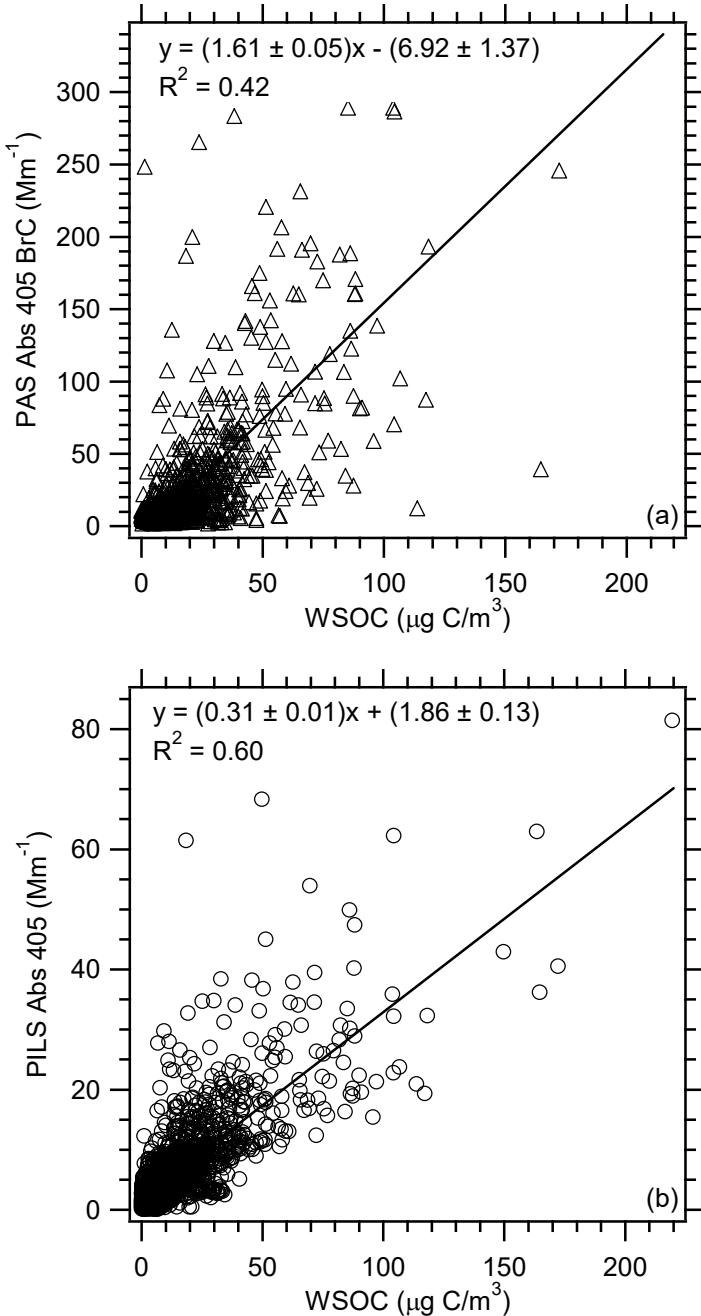

Figure 7. Correlation of (a) PAS total Abs 405 BrC and (b) PILS water-soluble Abs 405 vs. WSOC for all WE-CAN flights used in this analysis. Uncertainties with the least square regressions are one standard deviation.

419

424  
425

soluble Abs 405 between wildfires, and this leads to two branches (Branch 1 and Branch 2). This was also observed for levoglucosan vs. WSOC (not shown). While there is no overall correlation of levoglucosan vs. BrC absorption across all flights, there are correlations between these two species on an individual flight basis (e.g.,  $R^2$  value for Flight RF02 = 0.76 and Flight

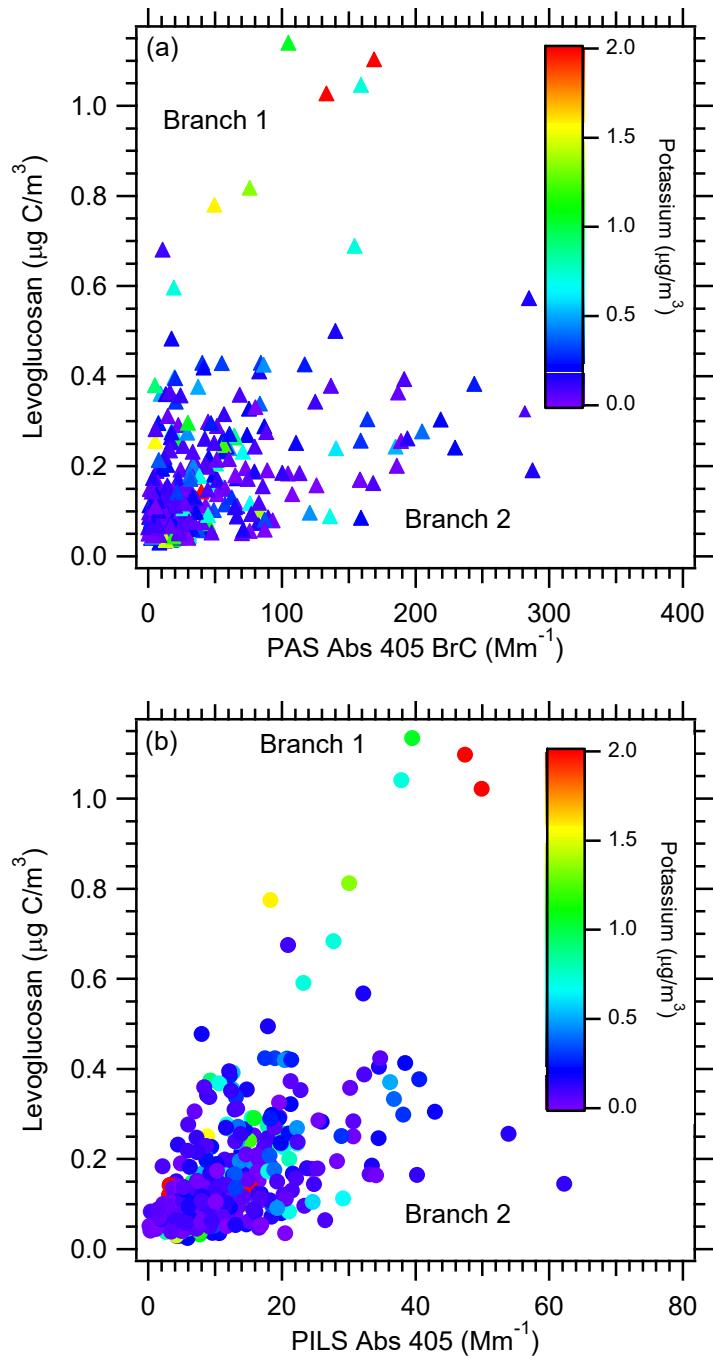

Figure 8. Correlations of levoglucosan on a carbon mass basis vs. (a) PAS total Abs 405 BrC and (b) PILS water-soluble Abs 405 for all WE-CAN flights used in this analysis with the data colored by the PILS water-soluble potassium concentrations. Branch 1 represents data with water-soluble potassium concentrations  $> 0.5 \mu\text{g}/\text{m}^3$  and Branch 2  $< 0.5 \mu\text{g}/\text{m}^3$ . In plot (a), the equation for the fit and  $R^2$  value for Branch 1 are  $y = (0.006 \pm 0.001)x + (0.027 \pm 0.049)$ ,  $R^2 = 0.60$  and for Branch 2  $y = (0.001 \pm 0.001)x + (0.118 \pm 0.006)$ ,  $R^2 = 0.22$ , respectively. In plot (b), the equation for the fit and  $R^2$  value for Branch 1 are  $y = (0.024 \pm 0.002)x - (0.081 \pm 0.038)$ ,  $R^2 = 0.76$  and for Branch 2  $y = (0.006 \pm 0.001)x + (0.073 \pm 0.007)$ ,  $R^2 = 0.35$ , respectively. Uncertainties with the least square regressions are one standard deviation.

426 RF11 = 0.60, not shown). When data from all flights are colored by the water-soluble potassium  
427 concentration, we observe that Branch 1, which had the highest levoglucosan concentrations,  
428 also has the highest water-soluble potassium concentrations ( $> 0.5 \mu\text{g}/\text{m}^3$ ). Levoglucosan and  
429 BrC absorption are much more highly correlated in Branch 1, than in Branch 2 for both the PILS  
430 ( $R^2$  values Branch 1 = 0.76 and Branch 2 = 0.35) and PAS ( $R^2$  values Branch 1 = 0.60 and  
431 Branch 2 = 0.22) BrC absorption. To further examine this, the times series of PILS water-  
432 soluble Abs 405, levoglucosan, potassium, and ammonium for Flights RF02 and RF11 are shown  
433 in Figure 9. Smoke impacted samples in Flight RF02 had higher concentrations of levoglucosan  
434 and water-soluble potassium and contributed to Branch 1. The data from Flight RF11  
435 contributed to Branch 2. In addition, elevated water-soluble potassium was observed in many of  
436 the plume intercepts during Flight RF02. But more elevated ammonium was observed for Flight  
437 RF11, which became even more prominent in smoke intercepts after 00:00 UTC, while water-  
438 soluble potassium was relatively less abundant. While ammonium was clearly more prominent,  
439 there was no correlation observed between ammonium and PAS total Abs 405 BrC or PILS  
440 water-soluble Abs 405 for the data contributing to Branch 2 (not shown). Water-soluble  
441 potassium is a known inorganic marker for biomass burning, although it is not as specific of a  
442 marker as levoglucosan as there are additional possible sources for water-soluble potassium  
443 [Schauer *et al.*, 2001] and water-soluble potassium is predominately emitted during only the  
444 flaming phase of a fire [Lee *et al.*, 2010]. It is possible this difference in timing of emissions is  
445 what leads to the different relationship of Abs 405 with levoglucosan than was observed for CO  
446 and WSOC. It has been observed in previous work looking at the size-resolved aerosol  
447 composition and single particle measurements from wildfire plumes that water-soluble potassium  
448 and levoglucosan appear in different sized particles than BrC and that there is non-uniform  
449 mixing of them [Di Lorenzo *et al.*, 2018; Lee *et al.*, 2016], which could also be a factor. These  
450 results from WE-CAN are further suggesting there may be a relationship between levoglucosan  
451 and water-soluble potassium in wildfire emissions that has not been observed in other types of  
452 burning, such as prescribed burning, residential burning, or controlled laboratory burns [Sullivan  
453 *et al.*, 2014, 2019].

454

### 455 **3.4. Evolution of BrC Absorption with Plume Age and Fire Dynamics**

456 The time since emission (i.e., the smoke age) was estimated for all possible wildfire  
457 plumes as the distance the plume was sampled from the source divided by the average wind  
458 speed at that particular sampling altitude. Only PILS-fraction collector samples that directly  
459 overlapped with a CO plume penetration are considered. To account for dilution, we normalized  
460 the BrC absorption to 3 different species. We examine the ratio of BrC absorption to WSOC,  
461  $\Delta\text{CO}$  (assuming a CO background of 100 ppbv), and levoglucosan.

462 Figure 10a presents the ratio of PAS total Abs 405 BrC to WSOC and PILS water-soluble  
463 Abs 405 to WSOC, Figure 10b presents the ratio of PAS total Abs 405 BrC to  $\Delta\text{CO}$  and PILS  
464 water-soluble Abs 405 to  $\Delta\text{CO}$ , and Figure 10c presents the ratio of PAS total Abs 405 BrC to  
465 levoglucosan and PILS water-soluble Abs 405 to levoglucosan as a function of time since  
466 emission. To better discern any trends, Figures S1-S3 show these 3 ratios for each smoke plume  
467 on an individual flight basis. If WSOC was lost with age due to evaporation of more volatile  
468 components or SOA formation were occurring with time since emission, CO would be expected  
469 to be more stable. It appears, however, that a similar pattern, perhaps with a bit more scatter for  
470 Abs 405 to WSOC, is observed for all of these ratios. Within a particular wildfire, there is no

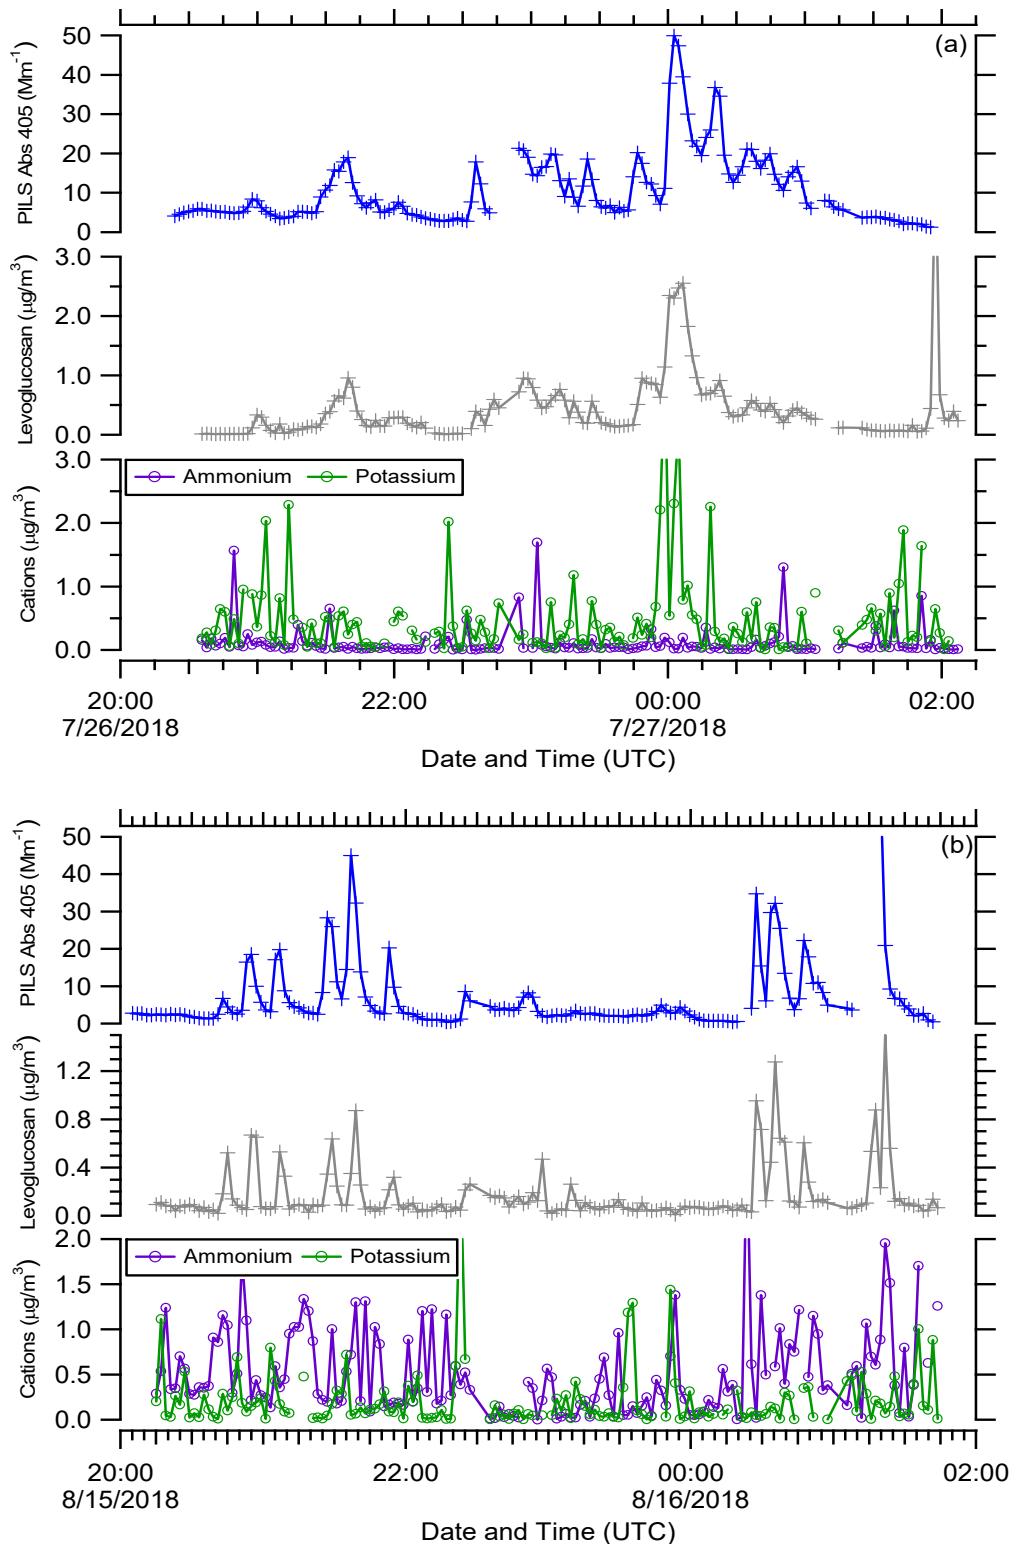

Figure 9. Time series from top to bottom of PILS water-soluble Abs 405, PILS levoglucosan, and PILS ammonium and water-soluble potassium for WE-CAN (a) Flight RF02 and (b) Flight RF11.

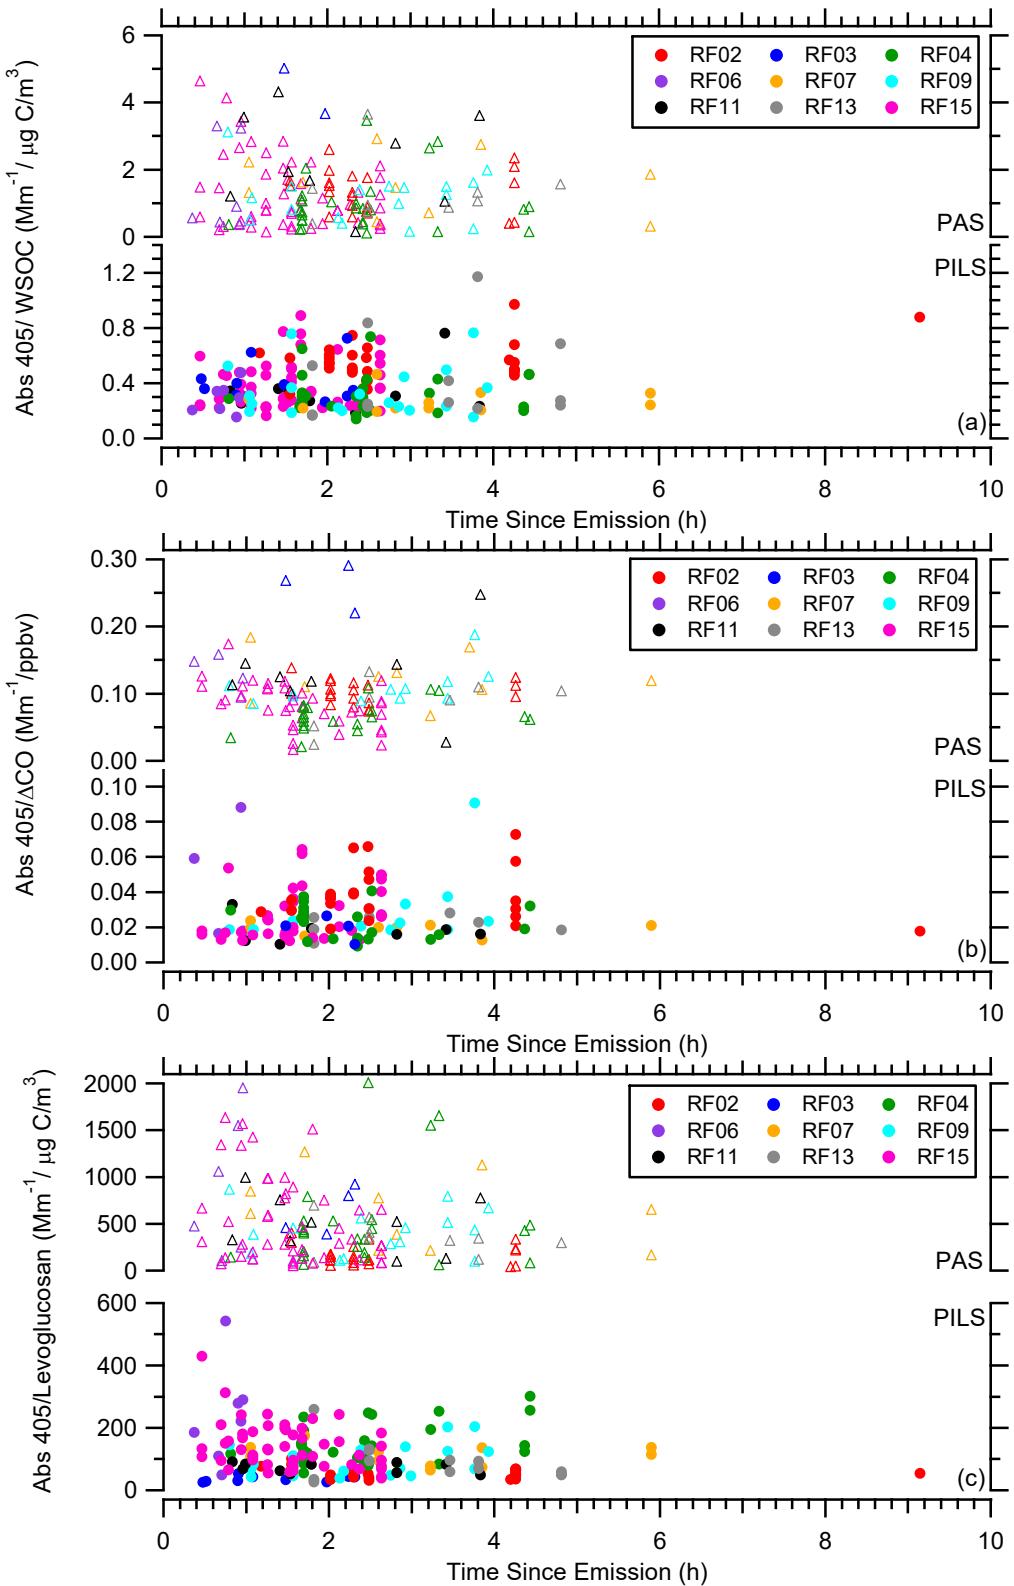

Figure 10. (a) Abs 405/WSOC, (b) Abs 405/ΔCO, and (c) Abs 405/levoglucosan as a function of time since emission for all WE-CAN flights with the data segregated by flight. In each plot the PAS total Abs 405 BrC is on top and the PILS water-soluble Abs 405 on the bottom.

472 clear evidence that the PILS water-soluble BrC absorption is affected by smoke age up to 9 h.  
473 For the PAS total BrC absorption, especially for the ratio to  $\Delta\text{CO}$ , there appears to be a possible  
474 decrease in the ratio in the first 2 h (see Figures S1i and S2i for Flight RF15 which best covered  
475 this period), suggesting a need to further explore changes in total BrC absorption near the source  
476 region.

477 A number of laboratory studies suggest the initial stages of photochemical aging  
478 increases light absorption (i.e., photoenhancement). This is then followed by a decrease in light  
479 absorption (i.e., photobleaching) [Hems and Abbatt, 2018; Saleh *et al.*, 2013; Sumlin *et al.*, 2017;  
480 Zhao *et al.*, 2015; Zhong and Jang, 2014]. However, it is challenging to directly compare this  
481 laboratory data to the ambient data collected during WE-CAN. But analysis of laboratory and  
482 ambient biomass burning samples found low molecular weight (< 400 Da) BrC undergoes rapid  
483 photobleaching on timescales of a few h, but high molecular weight (> 400 Da) BrC was stable  
484 for up to a few days [Di Lorenzo *et al.*, 2017; Wong *et al.*, 2019]. This suggests that the BrC  
485 sampled during WE-CAN could be composed mainly of high molecular weight species.

486 In addition, to investigate these ratios as a function of time since emission, the WE-CAN  
487 data had to be integrated across a smoke plume in order to incorporate the PILS-fraction  
488 collector measurements. Of course, a smoke plume itself was dynamic with concentrations  
489 being highest in the middle of the plume and more dilute on the edges. It is possible the  
490 averaging could contribute to the observed pattern of BrC absorption not changing with age.  
491 Forrister *et al.* [2015], who used plume transect averages of SEAC4RS data, reported a decrease  
492 in the total Abs 365/ $\Delta\text{CO}$  from ~0.13 to 0.07  $\text{Mm}^{-1}/\text{ppbv}$  in 5 h for smoke from the Rim Fire.  
493 Observations of smoke during FIREX, by contrast, indicated no clear trend with plume age  
494 [Washenfelder *et al.*, 2022; Zeng *et al.*, 2022] in a dataset where the majority of plume ages were  
495 less than 10 h. These varying results also suggest that other factors that contribute to changes in  
496 BrC absorption over time may still need to be explored.

497 As these three studies all examined Abs 365, the same series of plots shown in Figure 10  
498 are repeated for PILS water-soluble Abs 365 and shown in Figure S4. A similar pattern was  
499 observed at both wavelengths for the WE-CAN data. This suggests our results were not  
500 wavelength specific and further corroborate the results observed during FIREX.

501 An analysis of WE-CAN data by Palm *et al.* [2020] looking at the evolution of organic  
502 aerosol and BrC suggested that although changes in organic aerosol were likely occurring, there  
503 was a balance between dilution-driven evaporation and subsequent formation resulting in little  
504 change over time. It is hard to compare these results to our analysis as the Palm *et al.* [2020]  
505 work chose to focus only on the total organic aerosol and total Abs 405 BrC and did not examine  
506 the WSOC or water-soluble Abs 405. When examining the ratio of WSOC to  $\Delta\text{CO}$  as a function  
507 of time since emission (Figure S5) during WE-CAN, there was not clear evidence for formation  
508 or loss of WSOC being observed within a particular wildfire. But a recent analysis by Zeng *et al.*  
509 [2022] has shown in wildfire plumes that dilution-drive evaporation was likely playing a minor  
510 role compared to the effects of ozone on BrC.

511 In order to investigate the possible influence of fire dynamics on BrC absorption, the  
512 modified combustion efficiency (MCE) was calculated as the change in carbon dioxide divided  
513 by the sum of the change in carbon monoxide and carbon dioxide ( $\Delta\text{CO}_2/(\Delta\text{CO} + \Delta\text{CO}_2)$ ) on a  
514 molar basis [Ward and Radke, 1993]. A higher MCE value indicates a more intense or extended  
515 flaming phase as opposed to a smoldering phase. Within a particular wildfire there appeared to  
516 be no clear dependence of the ratio of BrC absorption to WSOC,  $\Delta\text{CO}$ , or levoglucosan on MCE  
517 (Figure 11 and Figures S6-S8), except that an overall lower Abs 405/levoglucosan ratio was

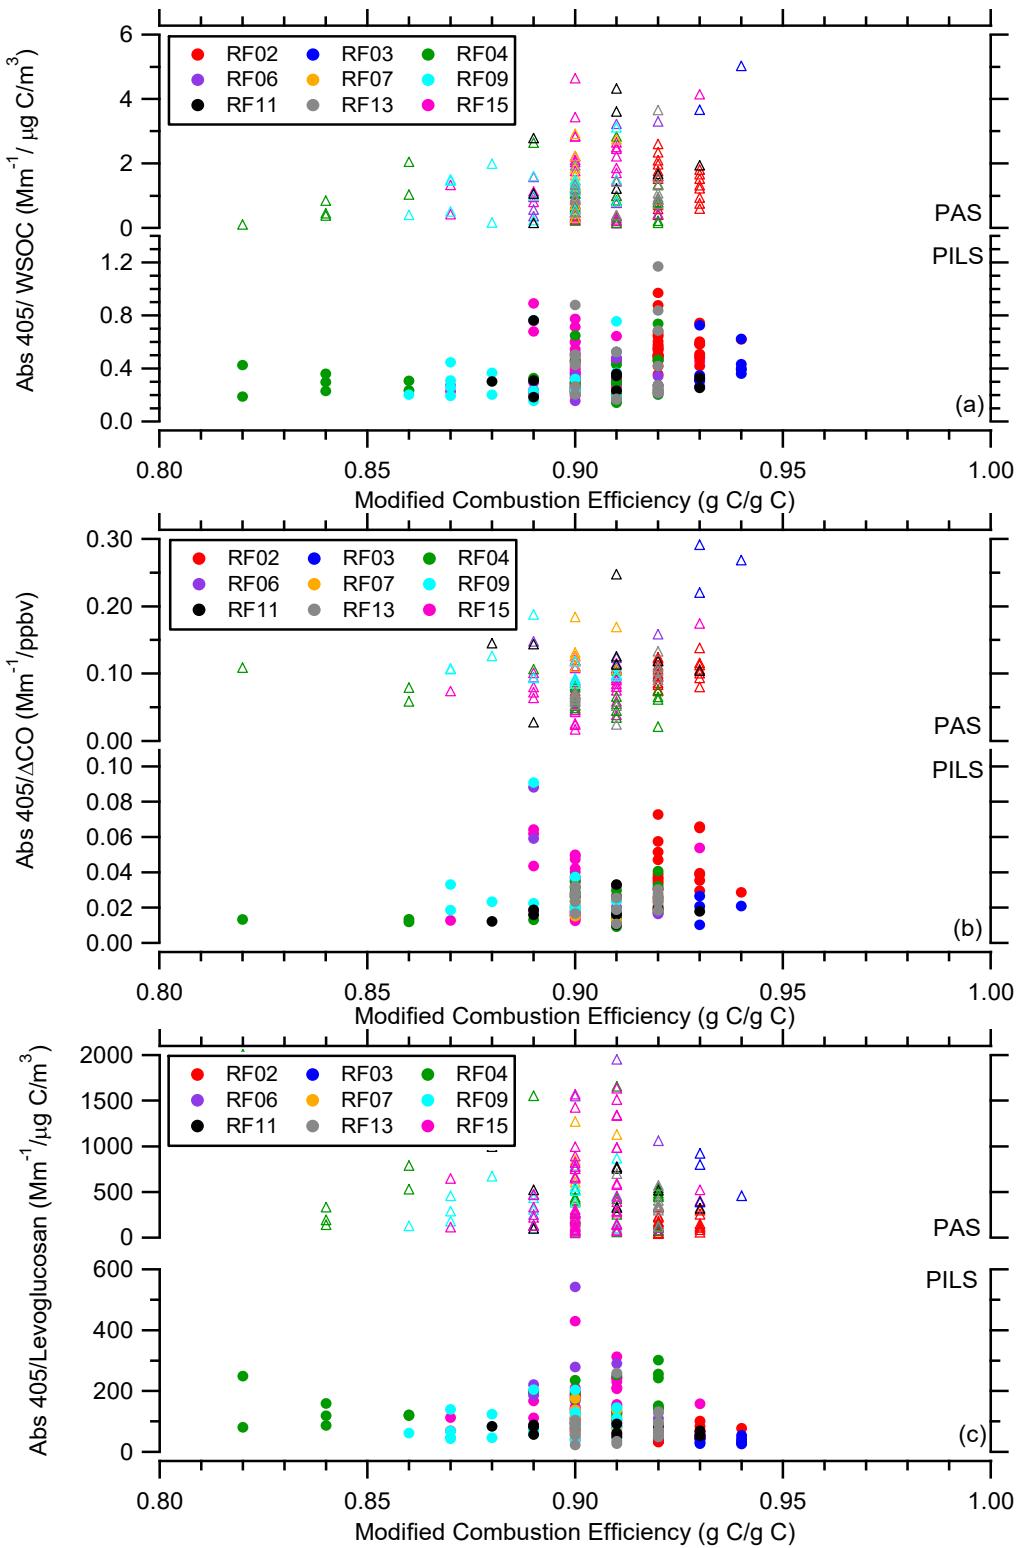

Figure 11. (a) Abs 405/WSOC, (b) Abs 405/ΔCO, and (c) Abs 405/levoglucosan as a function of modified combustion efficiency for all WE-CAN flights with the data segregated by flight. In each plot the PAS total Abs 405 BrC is on top and the PILS water-soluble Abs 405 on the bottom.

518 observed for the wildfires with higher MCE values (i.e., Flight RF02). This further supports the  
519 relationship between the highest potassium concentrations and the levoglucosan vs. Abs 405  
520 correlation (Figure 8) previously discussed as potassium is predominately emitted from the  
521 flaming phase of a fire [Echalar *et al.*, 1995; Lee *et al.*, 2010; Ward *et al.*, 1991].  
522

#### 523 4. Summary

524 A PILS-LWCC-TOC and PAS were deployed on the NSF/NCAR C-130 research aircraft  
525 during WE-CAN to examine aerosol absorption in wildfire smoke in the western U.S. This was  
526 the first deployment of the PILS-LWCC-TOC on a research aircraft. The PILS allowed for a 16  
527 s integrated measurement of the water-soluble BrC absorption and 4 s integrated measurement of  
528 WSOC. The data from the PILS and PAS were combined to investigate the water-soluble vs.  
529 total BrC absorption at 405 nm in the 20 wildfires sampled during WE-CAN. We show the  
530 following:  
531

- 532 1. WSOC, PILS water-soluble Abs 405, and PAS total Abs 405 BrC tracked each other in  
533 and out of the smoke plumes. BrC absorption was correlated with CO ( $R^2$  value for PAS  
534 = 0.76 and PILS = 0.55) and WSOC ( $R^2$  value for PAS = 0.42 and PILS = 0.60) during  
535 the entire study, illustrating the importance of biomass burning as a source of BrC  
536 absorption. A similar pattern was observed for levoglucosan, but with two data branches.  
537 Levoglucosan and BrC absorption were correlated ( $R^2$  values for PAS = 0.60 and PILS =  
538 0.76) in the first data branch and this subset of data was also characterized by the highest  
539 observed water-soluble potassium concentrations ( $> 0.5 \mu\text{g}/\text{m}^3$ ). This suggests there may  
540 be a relationship between levoglucosan and water-soluble potassium in wildfire  
541 emissions that has not generally been observed in other types of burning.  
542
- 543 2. Using the calculated UHSAS mass, the PILS water-soluble Abs 405 can be corrected to  
544 also account for the non-water-soluble fraction of the aerosol. The corrected PILS water-  
545 soluble Abs 405 showed good closure with the PAS total Abs 405 BrC, but with a factor  
546 of  $\sim 1.5$  to 2 difference. This difference can be explained by particle vs. bulk solution  
547 absorption measured by the PAS vs. PILS, respectively, as shown by Mie Theory  
548 calculations. During WE-CAN,  $\sim 45\%$  of the BrC absorption at 405 nm was due to  
549 water-soluble species.  
550
- 551 3. The ratio of water-soluble Abs 405 to WSOC,  $\Delta\text{CO}$ , or levoglucosan showed no clear  
552 dependence on fire dynamics or the time since emission up to 9 h. The total Abs 405  
553 BrC did show a slight decrease in the first 2 h, suggesting a need to further explore near  
554 source evolution.
