23

24 **Abstract.** Particulate nitrate ( $\text{NO}_3^-$ ) is ~~the~~ one of the dominant components of fine  
25 particles in China, especially during pollution episodes, and has a significant impact on  
26 human health, air quality, and climate. Here a comprehensive field campaign ~~which~~  
27 ~~focuses~~ that focuses on the atmospheric oxidation capacity and aerosol formation, and  
28 their effects in the Yangtze River Delta (YRD) ~~had been~~ was conducted from May to  
29 June, 2019 at a regional site in Changzhou, Jiangsu province in China. The  
30 concentration of  $\text{NO}_3^-$ , OH radical,  $\text{N}_2\text{O}_5$ ,  $\text{NO}_2$ ,  $\text{O}_3$ , and relevant parameters were  
31 measured simultaneously. We showed a high  $\text{NO}_3^-$  mass concentration with  $10.6 \pm 8.9$   
32  $\mu\text{g m}^{-3}$  on average, which accounted for 38.3 % of total water-soluble particulate  
33 components and 32.0 % of total  $\text{PM}_{2.5}$ , ~~and~~ followed by the proportion of sulfate,  
34 ammonium, and chloride by 26.0 %, 18.0 ~~%%~~, and 2.0 %, respectively. This result  
35 confirmed that the heavy nitrate pollution in eastern China not only happened in winter  
36 but also ~~summer time~~. High in the summertime. This study's high nitrate oxidation ratio  
37 (NOR) ~~during this study~~ emphasizes the ~~strong~~ solid atmospheric oxidation and fast  
38 nitrate formation capacity in YRD. It is found that  $\text{OH} + \text{NO}_2$  ~~at~~ during daytime  
39 dominates nitrate formation on clean days while  $\text{N}_2\text{O}_5$  hydrolysis ~~largely~~ vastly  
40 enhanced and ~~become~~ became comparable with that of  $\text{OH} + \text{NO}_2$  during polluted days  
41 (~~47.4~~ 67.2 % and ~~52.9~~ 30.2 %, respectively). An updated observed-constrain  
42 Empirical Kinetic Modeling Approach (EKMA) was used to assess the kinetic  
43 controlling factors of both local  $\text{O}_3$  and  $\text{NO}_3^-$  productions, which indicated that the  $\text{O}_3$ -  
44 targeted scheme ( $\text{VOCs}:\text{NO}_x = 2:1$ ) is ~~effective~~ adequate to mitigate the  $\text{O}_3$  and nitrate  
45 pollution coordinately during summertime in this region. Our results promote the  
46 understanding of nitrate pollution mechanisms and mitigation based on field  
47 observation and model simulation, and call for more ~~attentions~~ attention to nitrate  
48 ~~pollutions~~ pollution in the summertime.

## 51 1 Introduction

52 Chemical compositions of fine ~~particle~~particles have been measured in China during  
53 ~~the~~ past twenty years, and secondary inorganic aerosol is regarded as one of the  
54 dominant species in aerosol (Cao et al., 2012; Hagler et al., 2006; Zhao et al., 2013;  
55 Andreae et al., 2008). Since the Air Pollution Prevention and Control Action Plan, there  
56 has been a significant decrease ~~of~~in SO<sub>2</sub>, NO<sub>2</sub>, and PM<sub>2.5</sub> concentration in China, while  
57 the inorganic nitrate ratio in PM<sub>2.5</sub> increased and became the considerable component  
58 in PM<sub>2.5</sub> (Shang et al., 2021; Zhang et al., 2022). Therefore, ~~the~~a comprehensive  
59 understanding of ~~the~~ particulate nitrate ~~foramtion~~formation mechanism is essential and  
60 critical to ~~mitigate~~mitigating haze pollution in China.

61 ~~A massive~~Massive research ~~have~~has been ~~taken~~done in China ~~for investigating to~~  
62 ~~investigate~~ nitrate formation ~~mechanism~~mechanisms, and ~~a~~ basic framework has been  
63 established (Sun et al., 2006; Chang et al., 2018; Wu et al., 2019). In ~~the~~ daytime, NO<sub>2</sub>  
64 + OH radical oxidation (Reaction 1) is the major particulate nitrate formation pathway.  
65 The product (HNO<sub>3</sub>) reacts with alkaline ~~substanees~~substances in aerosol ~~by which,~~  
66 generating particulate nitrate. This pathway ~~is~~ mainly ~~controled~~controlled by  
67 ~~precurors~~precursors concentration as well as ~~the~~ gas-particle partition of gaseous nitric  
68 acid, and particulate nitrate depends on temperature, relative humidity (RH), NH<sub>3</sub>  
69 concentration, and aerosol acidity (Wang et al., 2009; Song and Carmichael, 2001;  
70 Meng et al., 2020; Zhang et al., 2021). At night, N<sub>2</sub>O<sub>5</sub> uptake is ~~an important~~a vital  
71 nitrate formation pathway (Reaction 4)(Chen et al., 2020; Wang et al., 2022). N<sub>2</sub>O<sub>5</sub> is  
72 formed through NO<sub>2</sub> + NO<sub>3</sub> (Reaction 3) and there ~~exsit~~exists a quick thermal  
73 equilibrium balance ( $K_{eq} = 5.5 \times 10^{-17} \text{ cm}^{-3} \text{ molecule}^{-1} \text{ s}^{-1}$ , 298 K). However, ~~there are~~  
74 two problems remain ambiguous in quantifying the contribution of N<sub>2</sub>O<sub>5</sub> uptake to  
75 nitrate formation. The first is the N<sub>2</sub>O<sub>5</sub> heterogeneous uptake ~~coefficient~~coefficient ( $\gamma$ )  
76 on ambient aerosol is highly varied with the range from 10<sup>-4</sup> to 10<sup>-1</sup> based on previous  
77 lab and field ~~measurments~~measurements (Bertram and Thornton, 2009; Brown et al.,  
78 2009; Wang et al., 2017c; Wang and Lu, 2016). The other one is ClNO<sub>2</sub> production

79 yield which ~~inflenees~~influences nitrate contribution ~~due~~due to the ~~large~~extensive  
 80 variation range (Phillips et al., 2016; Staudt et al., 2019; Tham et al., 2018). Both ~~the~~  
 81 two parameters are ~~hardly~~complex to well-predicted by current schemes. NO<sub>2</sub>  
 82 heterogeneous uptake has been found nonnegligible for nitrate formation, which can be  
 83 a vital pathway during heavy haze events, according to recent study (Qiu et al., 2019;  
 84 Chan et al., 2021). The uptake coefficient and nitrate yield remain uncertain, as same  
 85 as the N<sub>2</sub>O<sub>5</sub> heterogeneous reaction. Besides, N<sub>2</sub>O<sub>5</sub> homogeneous hydrolysis, ~~NO<sub>2</sub>~~  
 86 ~~heterogeneous uptake~~ and NO<sub>3</sub> radical oxidation have a minor contribution to  
 87 particulate nitrate under ambient ~~condition (Brown et al., 2009; Seinfeld and Pandis,~~  
 88 2016) conditions (Brown et al., 2009; Seinfeld and Pandis, 2016).

89 As a keycritical area of China's economy and industry, Yangtze River Delta (YRD)  
 90 has suffered severe air pollution during past decades, and fine particle pollution in YRD  
 91 has raised a widespread concern (Guo et al., 2014; Zhang et al., 2015; Zhang et al.,  
 92 2017; Ming et al., 2017; Xue et al., 2019). However, most ~~of these~~ research  
 93 ~~foeus~~focuses on wintertime PM<sub>2.5</sub> pollution and ~~lack of~~lacks measurements of critical  
 94 intermediate species and radicals to assess the importance of each nitrate formation  
 95 pathway. In this study, with the direct measurements of hydroxyl radical and the  
 96 reactive nitrogen compounds and chemical box model analysis, we explore the  
 97 characteristics of nitrate and precursors in YRD in the summer of 2019, the importance  
 98 of particulate nitrate formation pathways is quantified, and the ~~impact~~controlling  
 99 factors are explored. ~~Further~~A further suggestion for summer pollution prevention and  
 100 control ~~for~~in the local area is proposed.

101 **2 Site description and methods**

102 **2.1 The campaign site**

103 This campaign ~~had been taken~~took place at a ~~sub-urban~~suburban sanatorium from May  
104 30<sup>th</sup> to June 18<sup>th</sup>, 2019 ~~at~~, in Changzhou, China. Changzhou (119.95 °E, 31.79 °N) is  
105 located ~~at~~in Jiangsu province and about 150 km northwest of Shanghai. The sanatorium  
106 ~~which is~~, located ~~at~~ 420 m east of Lake Ge (one of the largest lakes in Jiangsu province,  
107 164 square kilometers), is surrounded by farmland and ~~fishpond~~fishponds. With the  
108 closest arterial traffic 1 km away, ~~there are~~several industry zones ~~are~~ 4 km to the east.  
109 The prevailing wind was from ~~the~~ south and ~~south-east~~southeast sectors (about 30 % of  
110 the time) compared to 20 % from the west sector, of which only 15 % came from the  
111 east. The wind speed was ~~normally~~usually lower than 5 m s<sup>-1</sup> with faster speed from the  
112 west. This site was influenced by ~~both~~ anthropogenic and biological sources with  
113 ~~occasionally~~occasional biomass burning.

114

115 **Figure 1** The location of ~~the~~ campaign site (red star), Changzhou, is ~~located~~ 150 km  
116 ~~at~~on the northwest side of Shanghai.

## 117 2.2 The instrumentation

118 ~~To comprehensive~~Multiple gaseous and particulate parameters were measured  
119 ~~simultaneously during the campaign to comprehensively~~ interpret the nocturnal  
120 atmospheric capacity and aerosol formation, ~~multiple gas and particle parameters were~~  
121 ~~measured simultaneously and the.~~ The related instruments are listed in Table 1. N<sub>2</sub>O<sub>5</sub>  
122 and Particle Number and Size Distribution (PNSD) were measured on ~~the~~ fourth floor  
123 of the sanatorium, which is the top of the building. Other instruments were ~~set up~~ placed  
124 in containers ~~placed~~ on the ground ~~and~~ 170 m northeast of the building. ~~These~~  
125 ~~instruments monitored through the roof of containers and and sampling inlets were at~~  
126 circa 5 m above the ground ~~through the containers' roof.~~

127 N<sub>2</sub>O<sub>5</sub> was measured by Cavity Enhanced Absorption Spectrometer (CEAS) based  
128 on Lambert-Beer's law which was developed by (Wang et al., 2017b). Briefly, air  
129 samples were drawn through the window and reached out of the wall 30 cm to prevent  
130 influence from surface deposition. ~~Aerosol~~The aerosol membrane filter was deployed  
131 before ~~sample~~the PFA ~~sampling~~ tube and changed every 2 hours ~~during the~~ night to  
132 avoid a decrease in N<sub>2</sub>O<sub>5</sub> transmission efficiency due to the increased loss of N<sub>2</sub>O<sub>5</sub> from  
133 the accumulated aerosols on the filter. N<sub>2</sub>O<sub>5</sub> was decomposed to NO<sub>3</sub> and NO<sub>2</sub> through  
134 preheating tube ~~which is~~ heat at 130 °C and detected within a PFA-coated resonator  
135 cavity ~~which is~~ heated at 110 °C to prevent the formation of N<sub>2</sub>O<sub>5</sub> by reversible reaction  
136 subsequently. At the end of each sampling cycle (5 min), ~~a~~ 30 s injection of high  
137 concentration NO (10 ppm, 20 ml min<sup>-1</sup>) ~~which~~ mixed with sample air was set to  
138 eliminate NO<sub>3</sub>-N<sub>2</sub>O<sub>5</sub> in the system. The NO titration spectrums were adopted as ~~the~~  
139 dynamic background spectrum by assuming ~~that~~ no H<sub>2</sub>O concentration variation in ~~a~~  
140 single sampling cycle. The loss of N<sub>2</sub>O<sub>5</sub> in the sampling system and filter ~~were~~was also  
141 considered ~~with~~during data correction. The limit of detection (LOD) was estimated  
142 to be 2.7 pptv (1  $\sigma$ ) with an uncertainty of 19 %.

143 OH radical measurement was conducted by Fluorescence Assay by Gas Expansion  
144 Laser-Induced Fluorescence techniques (FAGE-LIF), ~~ambient~~. Ambient air was

145 expanded through a 0.4 mm nozzle to low pressure in a detection chamber, ~~in~~ where  
 146 ~~OH radical irradiated by~~ the 308 nm laser pulse irradiated OH radical at a repetition  
 147 rate of 8.5 kHz (Chen et al., 2018). NO<sub>x</sub> and O<sub>3</sub> were monitored by commercial  
 148 monitors (Thermo-Fisher 42i and 49i). Volatile organic compounds (VOCs) were  
 149 measured by ~~using an~~ automated Gas Chromatograph equipped with a Mass  
 150 Spectrometer and flame ionization detector (GC-MS) with a time resolution of 60 min.  
 151 The photolysis frequencies were determined from the spectral actinic photon flux  
 152 density measured by ~~spectroradiometer (Bohn et al., 2008)~~ spectroradiometer (Bohn  
 153 et al., 2008).

154 PM<sub>2.5</sub> concentration was obtained by Tapered Element Oscillating Microbalance  
 155 (TEOM 1405, Thermo Scientific Inc). Aerosol surface concentration (S<sub>a</sub>) was  
 156 converted from particle number and size distribution, which was measured by Scanning  
 157 Mobility Particle Sizer (SMPS, TSI 3936) and Aerosol Particle Sizer (APS, TSI 3321)  
 158 and modified to the wet particle-state S<sub>a</sub> with a hygroscopic growth factor (Liu et al.,  
 159 2013). The uncertainty of the wet S<sub>a</sub> was ~ 30 %. Meanwhile, water-soluble particulate  
 160 ~~species as well as components and~~ their gaseous precursors were analyzed through the  
 161 Monitor for AeRosols and GAses in ambient air (MARGA, Chen et al. (2017)).  
 162 Meteorological data were also available, including the temperature, relative humidity  
 163 (RH), pressure, wind speed, and wind direction, ~~were also available~~.

164 **Table 1** The observed gas and particle parameters during the campaign.

Parameters	Detection of limit	Method	Accuracy
N <sub>2</sub> O <sub>5</sub>	2.7 pptv (1 σ, 1 min)	CEAS	± 19 %
OH	1.6 × 10 <sup>5</sup> cm <sup>-3</sup> (1 σ, 60 s)	LIF <sup>a</sup>	± 21 %
NO	60 pptv (2 σ, 1 min)	PC <sup>c</sup>	± 10 %
NO <sub>2</sub>	0.3 ppbv (2 σ, 1 min)	PC <sup>c</sup>	± 10 %
O <sub>3</sub>	0.5 ppbv (2 σ, 1 min)	UV photometry	± 5 %
VOCs	20-300 pptv (60 min)	GC-MS	± 15 %
PM <sub>2.5</sub>	0.1 μg m <sup>-3</sup> (1 min)	TEOM <sup>d</sup>	± 5 %
Photolysis frequencies	5 × 10 <sup>-5</sup> s <sup>-1</sup> (1 min)	SR <sup>e</sup>	± 10 %
PNSD	14 nm -700 nm (4 min)	SMPS, APS	± 10 %
HNO <sub>3</sub> , NO <sub>3</sub> , HCl	0.06 ppbv (30 min)	MARGA <sup>f</sup>	± 20 %

NH <sub>4</sub> <sup>+</sup> , NO <sub>3</sub> <sup>-</sup> , Cl <sup>-</sup> , SO <sub>4</sub> <sup>2-</sup>	0.05 μg m <sup>-3</sup> (30 min)	MARGA <sup>f</sup>	± 20 %
---	----------------------------------	--------------------	--------

165 <sup>a</sup> Laser-induced fluorescence; <sup>b</sup> Chemiluminescence; <sup>c</sup> Photolytic converter; <sup>d</sup> Tapered

### 168 2.3 The empirical kinetic ~~modelling~~ modeling approach

169 A box-model coupled with the Regional Atmospheric Chemical Mechanism version 2  
 170 (RACM2, Goliff, Stockwell & Lawson, 2013) is used to conduct the mitigation  
 171 strategies studies. The model is operated in one-hour time resolution with measurement  
 172 results of temperature, relative humidity, pressure, CO, NO<sub>2</sub>, H<sub>2</sub>O, photolysis  
 173 frequencies, and aggregated VOCs input to constrain the model. It should be noted that  
 174 HONO concentration is ~~simply~~ calculated by NO<sub>2</sub> times 0.02, ~~which is, as~~ suggested by  
 175 Elshorbany et al. (2012), and has been used in ~~the~~ box model before (Lou et al., 2022).  
 176 Long-lived species such as H<sub>2</sub> and CH<sub>4</sub> are ~~set~~ assumed as constants (550 ppbv and  
 177 1900 ppbv, respectively). ~~What's more~~ Moreover, a 13-hour constant loss rate of  
 178 unconstrained intermediate and secondary products, ~~which is~~ the result of synthetic  
 179 evaluating secondary simulation of secondary species, is set for representing the multi-  
 180 effects of deposition, transformation, and transportation.

181 The approaches ~~of~~ the chemical production of O<sub>3</sub> (P(O<sub>3</sub>)) and inorganic nitrate  
 182 (P(NO<sub>3</sub><sup>-</sup>)) are ~~using previously~~ described ~~expression in previous articles~~ (Tan et al., 2021;  
 183 Tan et al., 2018) ~~in~~ and expressed as Equation 1 and 4:

$$P(O_3) = F(O_3) - D(O_3) \quad \text{Eq1}$$

$$F(O_3) = k_{HO_2+NO}[NO][HO_2] + k_{(RO_2+NO)eff}[NO][RO_2] \quad \text{Eq2}$$

$$D(O_3) = k_{OH+NO_2}[OH][NO_2] + (k_{OH+O_3}[OH] + k_{HO_2+O_3}[HO_2] + k_{alkenes+O_3}[alkenes])[O_3] \quad \text{Eq3}$$

$$P(NO_3^-) = P(HNO_3) + P(pNO_3) \quad \text{Eq4}$$

$$P(HNO_3) = k_{OH+NO_2}[OH][NO_2] \quad \text{Eq5}$$

$$P(pNO_3) = 0.25(2 - \phi) C \gamma S_a [N_2O_5] \quad \text{Eq6}$$

184 briefly, P(O<sub>3</sub>) is net ozone production, which ~~is~~ calculated by peroxy radical + NO  
 185 oxidation (Eq. 2) minus ~~the~~ chemical loss of O<sub>3</sub> and NO<sub>2</sub> (Eq. 3). P(NO<sub>3</sub><sup>-</sup>) is constituted  
 186 by reaction OH + NO<sub>2</sub> (Eq. 5) and N<sub>2</sub>O<sub>5</sub> ~~heterogenous~~ heterogeneous uptake (Eq. 6).  
 187 Here, rate constants of reactions are obtained from NASA JPL Publication (~~Burkholder~~  
 188 ~~et al., 2015~~) or RACM2 (Goliff et al., 2013).  $\gamma$  is the N<sub>2</sub>O<sub>5</sub> uptake coefficient ~~which is~~  
 189 calculated from parameterization ( $\gamma_p$ , more details in chapter 3.3).  $\phi$  represents ClNO<sub>2</sub>

带格式的：下标

190 production yield through  $\text{N}_2\text{O}_5$  hydrolysis, and the mean value reported ~~in~~by Xia et al.  
191 (2020) ~~are~~is used in this work.

192 ~~Empirical~~The empirical Kinetic Modeling Approach (EKMA) was innovated ~~for~~  
193 ~~studying~~to study the effects of precursors ( $\text{VOCs}$ , and  $\text{NO}_x$ ) reactivity on the  
194 ~~region's~~region's ozone pollution by Kanaya et al., which ~~help~~helps recognize the  
195 region's susceptibility to precursors by weight and become a prevalent tool to study the  
196 process of ozone formation (Tan et al., 2018; Yu et al., 2020b; Kanaya et al., 2008).  
197 The prevention and control problem of pollutant generation can be transformed through  
198 ~~the~~ EKMA curve to reduce its precursors' emissions. Furthermore, the  
199 ~~precursors~~precursor reduction scheme needed for ~~total~~ pollutant ~~total~~ control is given  
200 qualitatively.  $\text{P}(\text{NO}_3^-)$  can also be analyzed through EKMA for the nonlinear secondary  
201 formation relationship with precursor reactivity. Here, ~~an~~ isopleth diagram of the net  
202 ozone production rate as functions of the reactivities of  $\text{NO}_x$  and  $\text{VOCs}$  can be derived  
203 from EKMA. In detail, 0.01 to 1.2 emission reduction strategy assumptions are  
204 exponential interpolation into 20 kinds of emission ~~situations~~situations of  $\text{NO}_x$  and  
205  $\text{VOCs}$ , respectively, which in total counts 400 scenarios.

## 206 2.4 The calculation of aerosol liquid water content

207 Aerosol liquid water content (ALWC) is calculated through ISORROPIA II  
208 (Fountoukis and Nenes, 2007). Forward mode is applied in this study. Furthermore,  
209 water-soluble ~~ions~~particulate components in  $\text{PM}_{2.5}$  and gaseous species ( $\text{NH}_3 + \text{HNO}_3 +$   
210  $\text{HCl}$ ) obtained from MARGA, along with RH and  $T_a$  are input as initial input. In  
211 addition, metastable aerosol state is chosen ~~since~~due to high RH during this campaign.

## 212 3 Result and discussion

### 213 3.1 Overview of measurements

214 The time used in this study is China Standard Time (UTC + 8) and the local sunrise and  
215 sunset time during the campaign were around 5 am and 7 pm, respectively. The whole  
216 campaign period is divided into ~~the~~four  $\text{PM}_{2.5}$  clean periods and four  $\text{PM}_{2.5}$  polluted  
217 periods (9 out of 14 days, ~~the~~ latter polluted periods ~~and~~days day refer to  $\text{PM}_{2.5}$  pollution

218 except specified description) according to the Chinese National Air Quality Standard  
 219 (CNAAQs) Grade I of daily  $PM_{2.5}$  concentrations ( $< 35.0 \mu g m^{-3}$ ). Figure 2 shows the  
 220 meteorological parameters, and gas-phase and particulate species timeseries during the  
 221 observation. During the campaign, the temperature was high and; the maximum reached  
 222  $34.5 \text{ }^\circ\text{C}$ , with an average of  $25.1 \pm 3.7 \text{ }^\circ\text{C}$ . RH changed drastically from 21 % to 88 %,  
 223 with a mean value at of  $58.9 \pm 14.0 \%$ . Mean The mean  $NO_2$  concentration was  $14.8 \pm$   
 224  $9.5 \text{ ppbv}$ . Meanwhile, the  $O_3$  average was  $54.6 \pm 28.8 \text{ ppbv}$ , exceeding CNAAQs Grade  
 225 II for a maximum daily average of 8 h ozone ( $160 \mu g m^{-3}$ ) on 14 out of 19 days and  
 226 exceeding  $200 \mu g m^{-3}$  on six days.

227  
 228 **Figure 2** Timeseries of  $NO_2$ ,  $O_3$ ,  $N_2O_5$ , OH radical,  $PM_{2.5}$  and water-soluble particulate  
 229 species components, temperature, and RH. The vertical dotted line represents the zero  
 230 clock. The black horizontal solid line in  $O_3$  and  $PM_{2.5}$  panel panels represents Chinese  
 231 national air quality standards standards for  $O_3$  and  $PM_{2.5}$  respectively. Top The top panel  
 232 color blocks represent the  $PM_{2.5}$  clean day (light green) and  $PM_{2.5}$  polluted day (salmon)  
 233 respectively.

234

235 Daytime OH radical ranged from  $2 \times 10^6$  to  $8 \times 10^6$  molecular  $cm^{-3}$  with a daily  
 236 peak over  $3 \times 10^6$  molecular  $cm^{-3}$ . Maximum OH radical reached  $8.18 \times 10^6$  molecular

237  $\text{cm}^{-3}$  in this campaign. ~~Comparing~~Compared with other summertime OH radical  
238 observed ~~campaign~~ in China, OH radical concentration in this site is relatively low but  
239 still on the same order of magnitude (Lu et al., 2012; Lu et al., 2013; Ma et al., 2022;  
240 Tan et al., 2017; Woodward-Massey et al., 2020; Yang et al., 2021).  $\text{N}_2\text{O}_5$  mean  
241 concentration was  $21.9 \pm 39.8$  pptv with a nocturnal average of  $61.0 \pm 63.1$  pptv and a  
242 daily maximum of over 200 pptv at eight nights. The maximum concentration of  $\text{N}_2\text{O}_5$   
243 ( $477.2$  pptv, 5 min resolution) appeared at 20:47 on June 8<sup>th</sup>. The average  $\text{NO}_3$  radical  
244 production rate  $\text{P}(\text{NO}_3)$  is  $2.1 \pm 1.4$  ppbv  $\text{h}^{-1}$  with nocturnal average  $\text{P}(\text{NO}_3)$   $2.8 \pm 1.6$   
245 ppbv  $\text{h}^{-1}$  and daytime  $\text{P}(\text{NO}_3)$   $2.2 \pm 1.4$  ppbv  $\text{h}^{-1}$ .  $\text{P}(\text{NO}_3)$  is about twice of documented  
246 value in Taizhou and North China Plain (Wang et al., 2017a; Wang et al., 2018b; Wang  
247 et al., 2020a), but close to another result in YRD before (Chen et al., 2019). ~~Average~~  
248 ~~of~~The average  $\text{PM}_{2.5}$  was  $34.6 \pm 17.8$   $\mu\text{g m}^{-3}$  with a maximum reach of  $163.0$   $\mu\text{g m}^{-3}$ .  
249 The water-soluble particulate components of  $\text{PM}_{2.5}$  are displayed as well, ~~the~~. The  
250 average  $\text{NO}_3^-$  concentration was  $10.6$   $\mu\text{g m}^{-3}$ , which accounts for 38.3 % mass  
251 concentration of water-soluble particulate components and 32.0 % total  $\text{PM}_{2.5}$ , while  
252 the proportion of sulfate, ammonium, and chloride ~~are~~is 26.0 %, 18 ~~%~~%, and 2.0 %  
253 respectively. To sum up, during the campaign period, the pollution of  $\text{PM}_{2.5}$  would be  
254 generally exacerbated ~~in general~~ on high  $\text{O}_3$  and  $\text{NO}_2$  days. Precipitation occurred  
255 during four clean processes receded pollutant concentration; otherwise, the pollution  
256 condition remained severe.

257 The mean diurnal variations (MDC) of temperature, RH,  $\text{NO}_2$ ,  $\text{O}_3$ ,  $\text{P}(\text{NO}_3)$ ,  $\text{N}_2\text{O}_5$ ,  
258 OH radical, and  $\text{PM}_{2.5}$  in different air quality are shown in Figure 3. The temperature,  
259 RH, and OH radical MDC show indistinctive ~~difference~~differences between clean  
260 ~~day~~days (CD) and polluted ~~day~~days (PD). The MDC of  $\text{NO}_2$  has two concentration  
261 peaks ~~appear~~that appear at 06:00 and 21:00 on CD, while at PD, its peak ~~appears~~appears  
262 at 20:00 and ~~maintain~~maintains a high level during the whole night.  $\text{O}_3$  diurnal pattern  
263 reflects a typical urban-influenced character with a maximum  $\text{O}_3$  peak that lasts four  
264 hours from 14:00 to 17:00 ~~with~~, while polluted-day  $\text{O}_3$  peak concentration is 1.2 higher

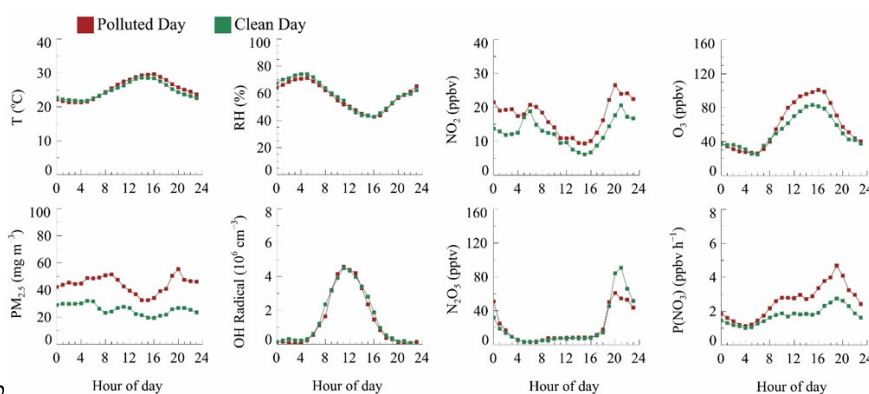

265 than clean-day. P(NO<sub>3</sub>) grows after the O<sub>3</sub> peak and maximum P(NO<sub>3</sub>) shows at 19:00  
 266 with an average value of 1.7 ppbv h<sup>-1</sup> on clean-day CD. By contrast, the mean polluted-  
 267 day P(NO<sub>3</sub>) is 2.6 ppbv h<sup>-1</sup>, and the maximum value reaches 4.7 ppbv h<sup>-1</sup>. In  
 268 contrast, the clean-day N<sub>2</sub>O<sub>5</sub> has a higher average and maximum concentration than PD,  
 269 which suggests a faster removal process during PD. PM<sub>2.5</sub> have has a similar trend with  
 270 P(NO<sub>3</sub>) and has a higher concentration during nighttime.

### 275 3.2 The evolution of nitrate pollution

276 Figure 4 (a) shows the relationship between nitrate and sulfate with water-soluble  
 277 ion-particulate components. Nitrate has positive correlation positively correlates with  
 278 particulate total water-soluble ion-particulate components, while the sulfate ratio  
 279 having has an inverse correlation. With PM<sub>2.5</sub> concentration increasing, nitrate  
 280 proportion increasing increases rapidly and keep keeps high weight at heavy PM<sub>2.5</sub>  
 281 period while sulfate appears ratio pears opposite phenomenon. Once the mass  
 282 concentration of total water-soluble ion-particulate component is over 30 μg m<sup>-3</sup>, the  
 283 mass fraction of nitrate in total water-soluble ion-particulate components is up to 50 %  
 284 on average. This result illustrates that particulate nitrate is one of the vital sources of

285 ~~explosive growth~~ particulate matter ~~explosive growth~~.

286 **Figure 4** (a) Particulate ion mass concentration ratio of nitrate and sulfate to water  
287 soluble ion. (b) NOR against RH, colored with temperature. (c) SOR against RH,  
288 colored with temperature.  
289

290

291 To further assess the conversion capacity of nitrate and sulfate in this site, the sulfur  
292 oxidation ratio (SOR) and the nitrogen oxidation ratio (NOR) are used ~~for indicating to~~  
293 ~~indicate the~~ secondary transformation ratio of SO<sub>2</sub> and NO<sub>2</sub>, respectively (Sun et al.,  
294 2006) (Sun et al., 2006). SOR and NOR are estimated using ~~the~~ formulae below:

295

$$\text{SOR} = \frac{n\text{SO}_4^{2-}}{n\text{SO}_4^{2-} + n\text{SO}_2} \quad \text{Eq7}$$

$$\text{NOR} = \frac{n\text{NO}_3^-}{n\text{NO}_3^- + n\text{NO}_2} \quad \text{Eq8}$$

296 ~~here~~ Where n refers to the molar concentration. ~~The, the~~ higher SOR and NOR represent  
297 more oxidation of gaseous species into a secondary aerosol. As depicted in Figure 4 (b-  
298 c), NOR ~~rapidly~~ increases at RH < 45 %, remains constant at 45 % < RH < 75 %~~%,~~  
299 and ends with a ~~sharply~~ increase at RH > 75 %. ~~In addition, NOR has inverse~~  
300 ~~correlation with temperature which reflects the importance of nighttime secondary~~  
301 ~~transformation and the influence of negative correlation of gas-solid equilibrium~~  
302 ~~between particulate nitrate and gaseous HNO<sub>3</sub>.~~ During the study period, not only is the  
303 average concentration of NO<sub>2</sub> ~~is~~ higher among PD<sub>7</sub>, but also there is ~~significantealso a~~  
304 ~~significant~~ difference between PD and CD NOR. The average values of NOR are 0.32  
305 in PD<sub>7</sub> ~~and~~ 0.25 in CD<sub>2</sub>, respectively, which manifests ~~that~~ the more secondary

带格式的：非上标/下标

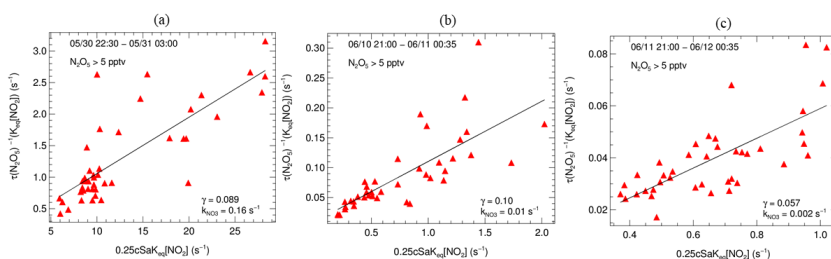

323 first method is a stationary-state approximation (Brown et al., 2003). By assuming that  
 324 the rates of production and loss of N<sub>2</sub>O<sub>5</sub> are approximately in balance, the total loss rate  
 325 of N<sub>2</sub>O<sub>5</sub> (k<sub>N<sub>2</sub>O<sub>5</sub></sub>) can be calculated through equation 9. The k<sub>N<sub>2</sub>O<sub>5</sub></sub> is main dominated by  
 326 N<sub>2</sub>O<sub>5</sub> heterogeneous uptake, since homogeneous hydrolysis of N<sub>2</sub>O<sub>5</sub> ~~contributes very~~  
 327 ~~little contribute tiny~~ (Brown and Stutz, 2012). N<sub>2</sub>O<sub>5</sub> uptake coefficient through steady-  
 328 state (note as γ<sub>s</sub>) is derived as equation 10. Here C is the mean molecule speed of N<sub>2</sub>O<sub>5</sub>,  
 329 and S<sub>a</sub> is the aerosol surface concentration.

$$\tau_{ss}(N_2O_5) = \frac{[N_2O_5]}{k_{R3.1}[NO_2][O_3]} = (k_{N_2O_5} + \frac{k_{NO_3}}{K_{eq}[NO_2]})^{-1} \quad \text{Eq9}$$

$$k_{N_2O_5} = 0.25 C \gamma_s S_a \quad \text{Eq10}$$

330 Due to the fast variety of NO<sub>3</sub> loss ~~rates~~ from VOCs, the steady-state method has  
 331 been unattainable in conditions affected by emission interferences. During the whole  
 332 campaign, we only retrieve three valid fitting results. As shown in Figure 5, the fitted  
 333 γ<sub>s</sub> ~~are~~ ranged from 0.057 to 0.123, which ~~are~~ comparable with Taizhou (0.041, Wang  
 334 et al. (2020a)) and much higher than other results in China (Yu et al., 2020a; Wang et  
 335 al., 2018a; Wang et al., 2020b; Wang et al., 2017a). The calculated k<sub>NO<sub>3</sub></sub> ranged from  
 336 0.002 to 0.16 s<sup>-1</sup>, represents drastic VOCs change during this campaign.

337  
 338 **Figure 5** Derived N<sub>2</sub>O<sub>5</sub> uptake coefficients from N<sub>2</sub>O<sub>5</sub> steady lifetime ( $\gamma(N_{2}O_{5}-S)_{s}$ )  
 339 with NO<sub>2</sub> and S<sub>a</sub>, plots (a-c) represent the linear fitting results ~~at~~ on the nights of 05/30,  
 340 06/10, and 06/11, respectively.

341 The other approach is the parameterization by (Yu et al., 2020a) which ~~is~~ depicted  
 342 as follows:

$$\gamma_{\text{P}} = \frac{4V_{\text{a}}}{cS_{\text{a}}} K_{\text{H}} \times 3.0 \times 10^4 \times [\text{H}_2\text{O}] \left( 1 - \frac{1}{\left(0.033 \times \frac{[\text{H}_2\text{O}]}{[\text{NO}_3^-]} + 1 + \left(3.4 \times \frac{[\text{Cl}^-]}{[\text{NO}_3^-]}\right)\right)} \right) \quad \text{Eq11}$$

343  
 344 ~~where~~Where  $V_{\text{a}}/S_{\text{a}}$  is the measured aerosol volume to surface area ratio by SMPS;  $K_{\text{H}}$   
 345 is ~~Henry's~~Henry's law coefficient which is set as 51 as recommended;  $[\text{NO}_3^-]$  and  $[\text{Cl}^-]$   
 346 are aerosol inorganic concentration measured by Marga;  $[\text{H}_2\text{O}]$  is aerosol water content  
 347 calculated through ISORROPIA II. ~~The parameterization calculated  $\text{N}_2\text{O}_5$  uptake~~  
 348 ~~coefficient (note as  $\gamma_{\text{P}}$ ) vary from 0.014 to 0.094 with average 0.035~~The valid  
 349 ~~parameterization calculated  $\text{N}_2\text{O}_5$  uptake coefficient (note as  $\gamma_{\text{P}}$ ) from May 30<sup>th</sup> to June~~  
 350 ~~08<sup>th</sup>, 2019, shows in Figure 6 a good consistency between the trends of  $\gamma_{\text{P}}$  and aerosol~~  
 351 ~~water content. Nighttime  $\gamma_{\text{P}}$  varies from 0.001 to 0.024 with an average of  $0.069 \pm$~~   
 352 ~~0.0050 in polluted condition and  $0.0036 \pm 0.0026$  in clean condition. The  $\text{N}_2\text{O}_5$  uptake~~  
 353 ~~coefficient shows a good correlation between RH and aerosol water content. For the~~  
 354  ~~$\text{N}_2\text{O}_5$  uptake coefficient, although particulate nitrate mass concentration increased~~  
 355 ~~during the pollution event, an antagonistic effect on the  $\text{N}_2\text{O}_5$  uptake coefficient was~~  
 356 ~~not obvious for the nitrate molarity decreasing.~~

357 ~~—~~Furthermore, we compare the difference between  $\gamma_{\text{S}}$  and  $\gamma_{\text{P}}^{\text{h}}$ . Taking the night  
 358 of May 30<sup>th</sup> as ~~an~~ example, the  ~~$\gamma_{\text{S}}$  is 0.40089~~ while  ~~$\gamma_{\text{P}}$  ranges from 0.021024~~ to  
 359 ~~0.037057~~ with ~~an~~ average value ~~as of~~  ~~$0.026013 \pm 0.0051$~~ . The difference between  
 360 steady-state and parameterization is significant; ~~one possible explanation is uncertainty~~  
 361 ~~for stationary-state approximation caused by local NO or VOCs emission (Brown et al.,~~  
 362 ~~2009; Chen et al., 2022). Another reason is that parameterization by Yu et al. ignores~~  
 363 ~~the impact of organic matter on the fine particle. The difference in aerosol composition~~  
 364 ~~between this work and Yu et al may also bring uncertainty. Overall consideration,  $\gamma_{\text{P}}$~~   
 365 ~~will be chosen for the  $\text{N}_2\text{O}_5$  heterogeneous uptake coefficient in later analysis and~~  
 366 ~~discussion.~~

367  
 368 **Figure 6** Results of  $N_2O_5$  uptake coefficients through parameterization ( $\gamma_p$ ). (a) shows  
 369 timeseries of  $\gamma_p$  and ISORROPIA II results of aerosol water content (AWC). (b) is the  
 370 box-plot of  $\gamma_p$  on the polluted day and clean day, the hollow square represents the mean  
 371 value, and the solid line across the box shows the median score for the data set, while  
 372 the top and bottom whiskers represent 90 % and 10 % value of  $\gamma_p$ , respectively.

### 373 3.4 Quantifying the contribution of nitrate formation pathways

374 After the  $N_2O_5$  uptake coefficient is counted, nitrate production potential ( $P(NO_3^-)$ ) can  
 375 be calculated. Here  $N_2O_5$  uptake coefficient is set as 0.035036 on clean day and 0.069  
 376 on polluted day, respectively, which is the average value derived from  
 377 parameterization, ~~while the~~ The production ratio of  $NO_3^-$  (by considering  $CINO_2$  yield  
 378 of 0.54) is set as 1.46 ~~from in the~~ former study (Xia et al., 2020). Gas particle distribution  
 379 is considered by the result of particular nitrate and gas-phase nitrate by MARGA (input  
 380  $HNO_3/NO_3^-$  ratio to the model as OH +  $NO_2$  nitrate production rate). ~~Subsequent~~  
 381 ~~discussion focuses on OH +  $NO_2$  and  $N_2O_5$  heterogeneous uptake~~  $NO_2$  heterogeneous  
 382 uptake coefficient is set as  $5.8 \times 10^{-6}$  depending on the report by Yu et al. (2021) which  
 383 is the result of 70% RH on urban grime.

384 The mean diurnal variations of the nitrate production potential of clean and polluted  
 385 day are depicted in Figure 67. The OH +  $NO_2$  pathway shows no significant difference  
 386 between clean and polluted day and ~~dominated~~ dominates clean day nitrate formation  
 387 potential. Since the level of OH and  $NO_2$  is less affected by the fine particle level.  
 388 However, the rapid increase of the  $N_2O_5$  heterogeneous uptake pathway on polluted day  
 389 is fatal, and its peak formation rate at night over the OH +  $NO_2$  pathway ~~which~~ can be

带格式的: 字体颜色: 文字 1

带格式的: 字体颜色: 文字 1

带格式的: 字体颜色: 文字 1

带格式的: 字体颜色: 文字 1

带格式的: 字体颜色: 文字 1

390 used to explain nighttime nitrate explosive growth.

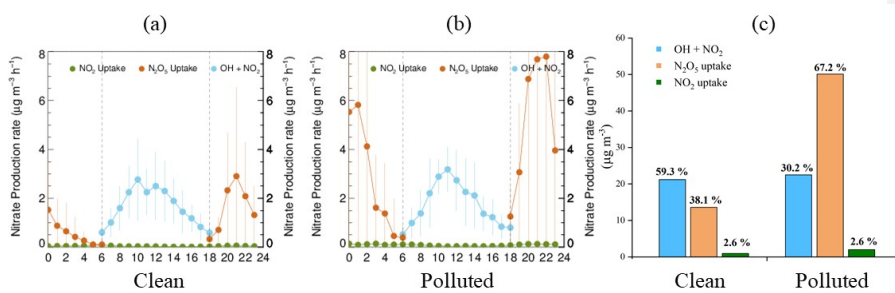

391 As shown as in Figure 6e7c, OH + NO<sub>2</sub> dominated dominates nitrate production on  
 392 clean day, while the N<sub>2</sub>O<sub>5</sub> uptake pathway only contributes 13.26 μg m<sup>-3</sup>. On polluted  
 393 days, the ability of N<sub>2</sub>O<sub>5</sub> uptake grows grows fast which reached 25.3, reaching 50.1 μg  
 394 m<sup>-3</sup>, while the OH pathway don't doesn't change too much. There is no distinct  
 395 difference in the daytime pathway (OH + NO<sub>2</sub>) between clean day and polluted day,  
 396 while the nighttime pathway ratio rises from 38.41% on clean day to 52.967.2% on  
 397 polluted day. The NO<sub>2</sub> heterogeneous uptake increases from 0.93 μg m<sup>-3</sup> on clean day to  
 398 2.0 μg m<sup>-3</sup> on polluted day, but the contribution proportion does not change obviously.  
 399 Both the higher N<sub>2</sub>O<sub>5</sub> uptake coefficient and higher S<sub>a</sub> on polluted day increase the  
 400 contribution of N<sub>2</sub>O<sub>5</sub> hydrolysis on particular nitrate is vital at pollution condition.

401

402

403

404 **Figure 67** The mean diurnal variations of the nitrate production potential of clean day(a)  
 405 and polluted day (b) and the P(NO<sub>3</sub>) distribution of clean and polluted day (c).

### 406 3.5 Mitigation strategies of particulate nitrate and ozone productions

407 We selected two pollution episodes (Episode I (2019.05.30 00:00 - 2019.06.02 00:00)

408 and IV (2019.06.14 17:30 - 2019.06.17 12:00)) to explore the mitigation way of ozone  
 409 and nitrate pollution. Figure 78 shows the EKMA of  $P(O_3)$  and  $P(NO_3^-)$  of these two  
 410 periods,  $O_3$  located at VOCs controlling area in the two pollution episodes, which  
 411 consist with previous YRD urban ozone sensitivity study (Jiang et al., 2018; Zhang et  
 412 al., 2020a; Xu et al., 2021). The best precursor reduction for  $O_3$  is VOCs:  $NO_x = 2:1$   
 413 while nitrate is located at the transition area, which means either of the precursors  
 414 reduction will mitigate nitrate pollution. For the regional and complex air pollution  
 415 characteristics in this region, a fine particle-targeting reduction scheme will aggravate  
 416  $O_3$  pollution. In contrast, the  $O_3$ -targeting scheme can mitigate  $O_3$  and fine particle  
 417 simultaneously.

418  
 419 **Figure 78** Isogram of  $P(O_3)$  and  $P(NO_3^-)$  of polluted episode I (2019.05.30 00:00 -  
 420 2019.06.02 00:00) and IV (2019.06.14 17:30 - 2019.06.17 12:00) with different  $NO_x$   
 421 and VOC reduction degree. The grey dash line represents the ridge line.

#### 422 4 Conclusion

423 A comprehensive campaign was conducted to interpret the atmospheric oxidation  
 424 capacity and aerosol formation during from May 30<sup>th</sup> to June 18<sup>th</sup>, 2019, in

425 Changzhou, China. The high O<sub>3</sub> and PM<sub>2.5</sub> ~~concentration~~concentrations confirm  
426 complex air pollution characteristics in Changzhou, and nitrate accounts for 38.3 %  
427 mass concentration of total water-soluble particulate components and 32.0 % of total  
428 PM<sub>2.5</sub>. In addition, the average values of NOR are 0.32 in PD, and 0.25 in CD. The  
429 positive correlation between NOR and RH and inverse correlation refer to the  
430 contribution of N<sub>2</sub>O<sub>5</sub> ~~heterogeneous~~heterogeneous uptake to nitrate formation.

431 Based on field observations of OH and related parameters, we show OH oxidation  
432 of the NO<sub>2</sub> pathway steadily ~~contribute~~contributes to nitrate formation no matter the  
433 clean or polluted period and domination clean day nitrate production (about 22 μg m<sup>-3</sup>).  
434 N<sub>2</sub>O<sub>5</sub> heterogeneous uptake contribution ~~grow rapidly~~proliferated on polluted day, from  
435 13.26 μg m<sup>-3</sup> (38.4% ~~in 1 %~~) on clean days to 25.350.1 μg m<sup>-3</sup> (52.9% ~~in 67.2 %~~) on  
436 polluted days. NO<sub>2</sub> heterogeneous uptake contributes minor to nitrate formation (2.6 %).

437 The precursor reduction simulation suggests the reduction ratio of VOCs: NO<sub>x</sub>  
438 equals 2:1 can simultaneously and effectively mitigate O<sub>3</sub> and fine particle pollution  
439 during the summertime complex pollution period in Changzhou. ~~In order to~~To more  
440 precisely and delicately establish a cooperative control scheme for regional O<sub>3</sub> and  
441 nitrate, the regional and long-time ~~field~~field campaigns are needed in the future, to  
442 analyze the seasonal and interannual variation of O<sub>3</sub> and nitrate and relevant parameters.
