

17 **Abstract.**

18 The co-polluted days by ozone (O<sub>3</sub>) and PM<sub>2.5</sub> (particulate matter with an  
19 aerodynamic equivalent diameter of 2.5 μm or less) (O<sub>3</sub>&PM<sub>2.5</sub>PD) were frequently  
20 observed in the Beijing–Tianjin–Hebei (BTH) region in warm seasons (April–October)  
21 of 2013–2020. We applied the 3-D global chemical transport model (GEOS-Chem) to  
22 investigate the chemical and physical characteristics of O<sub>3</sub>&PM<sub>2.5</sub>PD by composited  
23 analyses of such days that were captured by both the observations and the model. Model  
24 results showed that, when O<sub>3</sub>&PM<sub>2.5</sub>PD occurred, the concentrations of hydroxyl  
25 radical and total oxidant, sulfur oxidation ratio, and nitrogen oxidation ratio were all  
26 high, and the concentrations of sulfate at the surface were the highest among all  
27 pollution types. We also found unique features in vertical distributions of aerosols  
28 during O<sub>3</sub>&PM<sub>2.5</sub>PD; concentrations of PM<sub>2.5</sub> decreased with altitude near the surface  
29 but remained stable at 975–819 hPa. Process analyses showed that secondary aerosols  
30 (nitrate, ammonium and sulfate) had strong chemical productions at 913–819 hPa,  
31 which were then transported downward, resulting in the quite uniform vertical profiles  
32 at 975–819 hPa in O<sub>3</sub>&PM<sub>2.5</sub>PD. The weather patterns for O<sub>3</sub>&PM<sub>2.5</sub>PD were  
33 characterized by anomalous high-pressure system at 500 hPa as well as strong  
34 southerlies and high RH at 850 hPa. The latter resulted in the strong chemical  
35 productions around 850 hPa in O<sub>3</sub>&PM<sub>2.5</sub>PD. The physical and chemical characteristics  
36 of O<sub>3</sub>&PM<sub>2.5</sub>PD are quite different from those of polluted days by either O<sub>3</sub> alone or  
37 PM<sub>2.5</sub> alone, which have important implications for air quality management.

41 **1. Introduction**

42 Surface ozone ( $O_3$ ) and  $PM_{2.5}$  (particulate matter with an aerodynamic equivalent  
43 diameter of 2.5 micrometers or less) are important air pollutants in the atmosphere that  
44 have harmful effects on public health (Gao and Ji, 2018; Jiang et al., 2019), ecosystems  
45 (Ren et al., 2011; Yue et al., 2017), and crops (Wang et al., 2005; Wang et al., 2007).  
46 Surface  $O_3$  is a secondary pollutant produced by photochemical oxidation of volatile  
47 organic compounds (VOCs) and nitrogen oxides ( $NO_x \equiv NO+NO_2$ ) in the presence of  
48 intense ultraviolet light, and the major  $PM_{2.5}$  components (nitrate ( $NO_3^-$ ), ammonium  
49 ( $NH_4^+$ ), sulfate ( $SO_4^{2-}$ ), black carbon (BC), organic carbon (OC)) are mainly caused by  
50 anthropogenic emissions of aerosols and aerosol precursors. Although surface  $O_3$  and  
51  $PM_{2.5}$  have different formation mechanisms, they are coupled through the common  
52 precursors ( $NO_x$  and VOCs) and photochemical reactions (Chu et al., 2020). Since 2013,  
53 stringent clean air actions have been implemented to improve air quality in China (State  
54 Council of the People's Republic of China, 2013, 2018). However,  $O_3$  concentrations  
55 increased unexpectedly, while  $PM_{2.5}$  concentrations decreased drastically in the past  
56 years (Li et al., 2019). The co-polluted days by  $O_3$  and  $PM_{2.5}$  (concentrations of both  
57  $O_3$  and  $PM_{2.5}$  exceed the national air quality standards on the same day, hereafter  
58 referred to as  $O_3$ & $PM_{2.5}$ PD) were also reported (Dai et al., 2019). Therefore, it is  
59 fundamental to examine the chemical and physical characteristics of  $O_3$ & $PM_{2.5}$ PD.

60 The Beijing–Tianjin–Hebei (BTH) region is the most populated region in northern  
61 China. In the past few years, concentrations of  $O_3$  and  $PM_{2.5}$  in the BTH were among  
62 the highest in China. The observations from China National Environmental Monitoring  
63 Center (CNEMC) showed that the mean and maximum MDA8 (daily maximum 8-h  
64 average)  $O_3$  in North China in summer of 2019 were 83 ppb and 129 ppb, respectively,  
65 and the summer mean MDA8  $O_3$  increased with a trend of 3.3 ppb  $a^{-1}$  over 2013–2019  
66 (Li et al., 2020). Gong et al. (2020) reported that  $O_3$  polluted days (i.e., MDA8  $O_3$

67 concentration exceeds 80 ppb) in May-July in the BTH increased from 35 days in the  
68 year of 2014 to 56 days in 2018. As for observed PM<sub>2.5</sub>, the concentration averaged  
69 over BTH had a decreasing trend of 10  $\mu\text{g m}^{-3} \text{ yr}^{-1}$  over 2013-2019, and the mean value  
70 was  $79 \pm 17 \mu\text{g m}^{-3}$  over these years (Li et al., 2020). BTH also had the highest  
71 frequency and intensity of severe haze pollution days (i.e., days with daily mean PM<sub>2.5</sub>  
72 concentration exceeding 150  $\mu\text{g m}^{-3}$ ) in China from 2013 to 2017, with an observed  
73 mean frequency of 21.2 d  $\text{yr}^{-1}$  and an observed mean intensity of 231.6  $\mu\text{g m}^{-3}$  (Dang  
74 and Liao, 2019).

75 The interactions between O<sub>3</sub> and PM<sub>2.5</sub> have been reported in previous studies.  
76 Zhu et al. (2019) examined the spatial-temporal characteristics of the correlations  
77 between observed O<sub>3</sub> and PM<sub>2.5</sub> at 1497 sites in China for 2016 and found that O<sub>3</sub>-  
78 PM<sub>2.5</sub> had the highest positive correlations (correlation coefficients > +0.7) in July in  
79 southern China and the largest negative correlations (r values < -0.5) during January in  
80 northern China. Li et al. (2019) used the GEOS-Chem model to analyze the O<sub>3</sub>-PM<sub>2.5</sub>  
81 relationship in northern China and found that O<sub>3</sub> production was suppressed under high  
82 PM<sub>2.5</sub> conditions (PM<sub>2.5</sub> concentrations > 60  $\mu\text{g m}^{-3}$ ) because of the reactive uptake of  
83 hydrogen oxide radicals (HO<sub>x</sub>) by aerosol particles. Chu et al. (2020) analyzed the  
84 observed daily PM<sub>2.5</sub> and O<sub>3</sub> concentrations in 114 cities in China during years of 2013-  
85 2018 and found that the correlations between O<sub>3</sub> and PM<sub>2.5</sub> tended to change from  
86 negative in 2013 to positive in 2018 in China as air quality improved.

87 Few previous studies have examined the co-occurrence of O<sub>3</sub> and PM<sub>2.5</sub> pollution  
88 (MDA8 O<sub>3</sub> > 80 ppb and PM<sub>2.5</sub> > 75  $\mu\text{g m}^{-3}$ ). Zong et al. (2021) used the obliquely  
89 rotated principal component analysis in the T-mode (T-PCA) method to identify the  
90 synoptic weather pattern associated with O<sub>3</sub>&PM<sub>2.5</sub>PD in eastern China during  
91 summer of 2015–2018, and found that O<sub>3</sub>&PM<sub>2.5</sub>PD were associated with a stable

92 western Pacific subtropical high ridge, which brought warm and moist air flow from  
93 the East China Sea to the eastern China to promote hygroscopic growth of fine  
94 particulate matter in BTH and northern YRD. Dai et al. (2021) analyzed O<sub>3</sub>&PM<sub>2.5</sub>PD  
95 in the YRD for April-October of 2013-2019 by using observations and reported that  
96 the co-polluted days occurred mainly in April (29.6% of co-polluted days occurred in  
97 April), May (23.0%), June (19.5%), and October (10.8%) under meteorological  
98 conditions of higher relative humidity, higher surface air temperature, and lower wind  
99 speed relative to the days with O<sub>3</sub> pollution alone. Qin et al. (2021) investigated  
100 O<sub>3</sub>&PM<sub>2.5</sub>PD by using the hourly observed concentrations of water-soluble ions, OC,  
101 and elemental carbon (EC) in 2019 in cities of Nanjing and Changzhou. They found  
102 that inorganic aerosols mainly existed as NH<sub>4</sub>NO<sub>3</sub> and the correlation coefficients  
103 between the secondary components NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, and SO<sub>4</sub><sup>2-</sup> were relatively high during  
104 O<sub>3</sub>&PM<sub>2.5</sub>PD in 2019, indicating a significant formation of secondary inorganic  
105 aerosols. Although these studies have discussed the meteorological conditions and  
106 some chemical characteristics of O<sub>3</sub>&PM<sub>2.5</sub>PD, the understanding of O<sub>3</sub>&PM<sub>2.5</sub>PD  
107 was quite limited because of the limited observations of chemical species involved.

108 In this work, we take advantage of the comprehensive chemical mechanism of  
109 the global chemical transport model to have better understanding of O<sub>3</sub>&PM<sub>2.5</sub>PD. We  
110 apply the 3-D global chemical transport model (GEOS-Chem) to simulate  
111 O<sub>3</sub>&PM<sub>2.5</sub>PD in BTH in years of 2013-2020, and investigate the chemical and  
112 physical characteristics of O<sub>3</sub>&PM<sub>2.5</sub>PD by composited analyses of such days that are  
113 captured by both the observations and the model. The objectives of this study are: 1)  
114 to examine the underlying chemical mechanisms for O<sub>3</sub>&PM<sub>2.5</sub>PD in BTH for warm  
115 seasons (April-October) of 2013-2020 by comparing O<sub>3</sub>&PM<sub>2.5</sub>PD with polluted days  
116 by O<sub>3</sub> alone or by PM<sub>2.5</sub> alone, and 2) to identify the weather patterns that are

117 associated with O<sub>3</sub>&PM<sub>2.5</sub>PD in BTH. The observations, the reanalyzed  
118 meteorological data, the GEOS-Chem model, and the process analysis are described  
119 in Section 2. The observed O<sub>3</sub>&PM<sub>2.5</sub>PD are presented in Section 3.1. The evaluation  
120 of simulated concentrations of O<sub>3</sub> and PM<sub>2.5</sub> as well as the simulated pollution days by  
121 O<sub>3</sub> and/or PM<sub>2.5</sub> are shown in Section 3.2. The underlying mechanisms of  
122 O<sub>3</sub>&PM<sub>2.5</sub>PD are shown in Section 3.3. In Section 3.4, the meteorological conditions  
123 for the co-occurrence of O<sub>3</sub> and PM<sub>2.5</sub> pollution are investigated. The conclusions are  
124 presented in Section 4.

125

## 126 **2. Methods**

### 127 **2.1 Observed O<sub>3</sub> and PM<sub>2.5</sub> concentrations**

128 Hourly concentrations of PM<sub>2.5</sub> and O<sub>3</sub> in China over the years of 2013-2020  
129 were taken from the public website of CNEMC (<https://air.cnemc.cn:18007/>, last  
130 access: 17 November 2022). To ensure data quality, the daily mean PM<sub>2.5</sub>  
131 concentration was calculated when there were valid data for more than 20 h during  
132 that day and the MDA8 O<sub>3</sub> concentration was calculated when there were valid data  
133 for at least 6 h for each 8 h. For the calculation of monthly and annual mean  
134 concentrations, the number of days with valid concentrations had to be more than 15  
135 in each month. The spatial distribution of the 79 valid sites within BTH (37-41°N,  
136 114-118°E, the black rectangle) is shown in Fig. 1. For model evaluation, the  
137 observed concentrations were averaged over sites within each of the 0.5° latitude ×  
138 0.625° longitude MERRA-2 grid cell. There are 18 model grids in BTH. Note that the  
139 observed O<sub>3</sub> concentrations from this network have a unit of μg m<sup>-3</sup>. For the  
140 consistency of observed and simulated O<sub>3</sub> concentrations, 1 μg m<sup>-3</sup> of O<sub>3</sub> is  
141 approximately 0.5 ppb under the conditions of 298 K and 1013 hPa. The observed O<sub>3</sub>

142 concentrations reported by the CNEMC were under standard conditions of 273 K and  
143 1013 hPa before 31 August 2018 and were under standard conditions of 298 K and  
144 1013 hPa afterwards ([http://www.mee.gov.cn/  
xxgk2018/xxgk/xxgk01/201808/t20180815\\_629602.html](http://www.mee.gov.cn/xxgk2018/xxgk/xxgk01/201808/t20180815_629602.html), last access: 17 November  
145 2022), which were accounted for as O<sub>3</sub> concentrations were converted to ppb.

147 According to the National Ambient Air Quality Standard of China (GB3095-  
148 2012), O<sub>3</sub> (PM<sub>2.5</sub>) concentration exceeds the national air quality standard if the MDA8  
149 O<sub>3</sub> (daily mean PM<sub>2.5</sub>) concentration is higher than 160 μg m<sup>-3</sup> (75 μg m<sup>-3</sup>). In this  
150 study, we define O<sub>3</sub> polluted days (hereafter called ‘O<sub>3</sub>PD’) for days with MDA8 O<sub>3</sub>  
151 concentration > 160 μg m<sup>-3</sup>, PM<sub>2.5</sub> polluted days (hereafter called ‘PM<sub>2.5</sub>PD’) with  
152 daily mean PM<sub>2.5</sub> concentration > 75 μg m<sup>-3</sup>, and the co-pollution days by O<sub>3</sub> and  
153 PM<sub>2.5</sub> (O<sub>3</sub>&PM<sub>2.5</sub>PD) with daily MDA8 O<sub>3</sub> concentration > 160 μg m<sup>-3</sup> as well as the  
154 daily mean PM<sub>2.5</sub> concentration > 75 μg m<sup>-3</sup>.

155

## 156 **2.2 Reanalyzed meteorological fields**

157 Meteorological fields were obtained from the Version 2 of Modern Era  
158 Retrospective-analysis for Research and Application (MERRA2), which were  
159 generated by the NASA Global Modeling and Assimilation Office (GMAO). The  
160 MERRA2 data have a horizontal resolution of 0.5° latitude × 0.625° longitude and  
161 72 vertical layers (Molod et al., 2015). To analyze the meteorological conditions for  
162 O<sub>3</sub>&PM<sub>2.5</sub>PD, vertical pressure velocity (OMEGA), planetary boundary layer height  
163 (PBLH), temperature (T), relative humidity (RH), surface incoming shortwave flux  
164 (SWGDN) are used. Note that the temporal resolution for PBLH, T, and SWGDN is  
165 1h, and that for OMEGA and RH is 3h. Daily mean geopotential heights at 850 and  
166 500 hPa from the National Center for Environmental Prediction (NCEP) and National

167 Center for Atmospheric Research (NCAR) global reanalysis with a resolution of 2.5°  
168 latitude by 2.5° longitude are also utilized in this study.

169

### 170 **2.3 Observed aerosol optical depth**

171 We obtained the version 3 datasets of observed daily aerosol optical depth  
172 (AOD) of level 2 (improved cloud screened and quality-assured) from Aerosol  
173 Robotic Network (AERONET, [https://aeronet.gsfc.nasa.gov/new\\_web/index.html](https://aeronet.gsfc.nasa.gov/new_web/index.html), last  
174 access: 17 November 2022) established by NASA and LOA-PHOTONS (Giles et al.,  
175 2019). Three sites in the BTH region have observations available over 2013-2020,  
176 including Beijing (39.97°N, 116.38°E), Beijing-CAMS (39.93°N, 116.31°E), and  
177 Xianghe (39.75°N, 116.96°E). The AOD values at 440 nm and 675 nm at these three  
178 sites are analyzed in this study.

179

### 180 **2.4 GEOS-Chem model**

181 We simulated O<sub>3</sub> and PM<sub>2.5</sub> using the nested version of the 3-D global chemical  
182 transport model (GEOS-Chem, version 11-01) driven by the MERRA2  
183 meteorological data. The nested domain was set over Asia (60°-150°E, 11°S-55°N)  
184 with a horizontal resolution of 0.5° latitude × 0.625° longitude, and the chemical  
185 boundary conditions were provided by the global GEOS-Chem simulation with 2.5°  
186 latitude × 2.5° longitude horizontal resolution.

187 The GEOS-Chem model includes fully coupled O<sub>3</sub>-NO<sub>x</sub>-hydrocarbon and  
188 aerosol chemistry mechanism (Bey et al., 2001; Pye et al., 2009) to simulate aerosols  
189 including SO<sub>4</sub><sup>2-</sup> (Park et al., 2004), NO<sub>3</sub> (Pye et al., 2009), NH<sub>4</sub><sup>+</sup>, BC and OC (Park  
190 et al., 2003), mineral dust (Fairlie et al., 2007), and sea salt (Alexander et al., 2005) as

191 well as the gas-phase pollutants such as NO<sub>x</sub> and O<sub>3</sub>. Over the Asian domain, the  
192 anthropogenic emissions of OC, BC, carbon monoxide (CO), sulfur dioxide (SO<sub>2</sub>),  
193 NO<sub>x</sub>, ammonia (NH<sub>3</sub>), and VOCs were obtained from the Multi-resolution Emission  
194 Inventory for China (MEIC), which includes emissions from industry, power,  
195 residential and transportation sectors for years of 2014-2017 (Li et al., 2017; Zheng et  
196 al., 2018), 2019 and 2020 (Zheng et al., 2021). Emissions in 2018 were obtained by  
197 the interpolation of those in 2017 and 2019 for each grid due to the lack of publicly  
198 accessible emission inventories for that year. The biogenic emissions in GEOS-Chem  
199 are simulated using MEGAN v2.1 (Guenther et al., 2012).

200 The hourly O<sub>3</sub> and PM<sub>2.5</sub> concentrations for the years of 2013-2020 were  
201 simulated by the GEOS-Chem model which were driven by MERRA-2  
202 meteorological fields. The model was spined up for 6 months before the integration  
203 over the studied time period.

204

## 205 **2.5 Process analysis**

206 Process analysis (PA) was applied to identify the relative importance of  
207 atmospheric processes in O<sub>3</sub>&PM<sub>2.5</sub>PD. PA has been widely used in previous studies  
208 to examine the key processes contributing to air pollution episodes (Gonçalves et al.,  
209 2009; Dang and Liao, 2019; Gong and Liao, 2019) as well as the interannual and  
210 decadal variations of air pollutants (Mu and Liao, 2014; Lou et al., 2015). Five major  
211 processes that influence O<sub>3</sub> and PM<sub>2.5</sub> concentrations were diagnosed at every time  
212 step, including net chemical production, dry deposition, horizontal advection, vertical  
213 advection, and diffusion, for the regional pollution days (days with more than half of  
214 the sites in BTH experiencing pollutions). We carried out PA for O<sub>3</sub>SPD (exclude  
215 O<sub>3</sub>&PM<sub>2.5</sub>PD from O<sub>3</sub>PD), PM<sub>2.5</sub>SPD (exclude O<sub>3</sub>&PM<sub>2.5</sub>PD from PM<sub>2.5</sub>PD), and

216 O<sub>3</sub>&PM<sub>2.5</sub>PD over BTH.

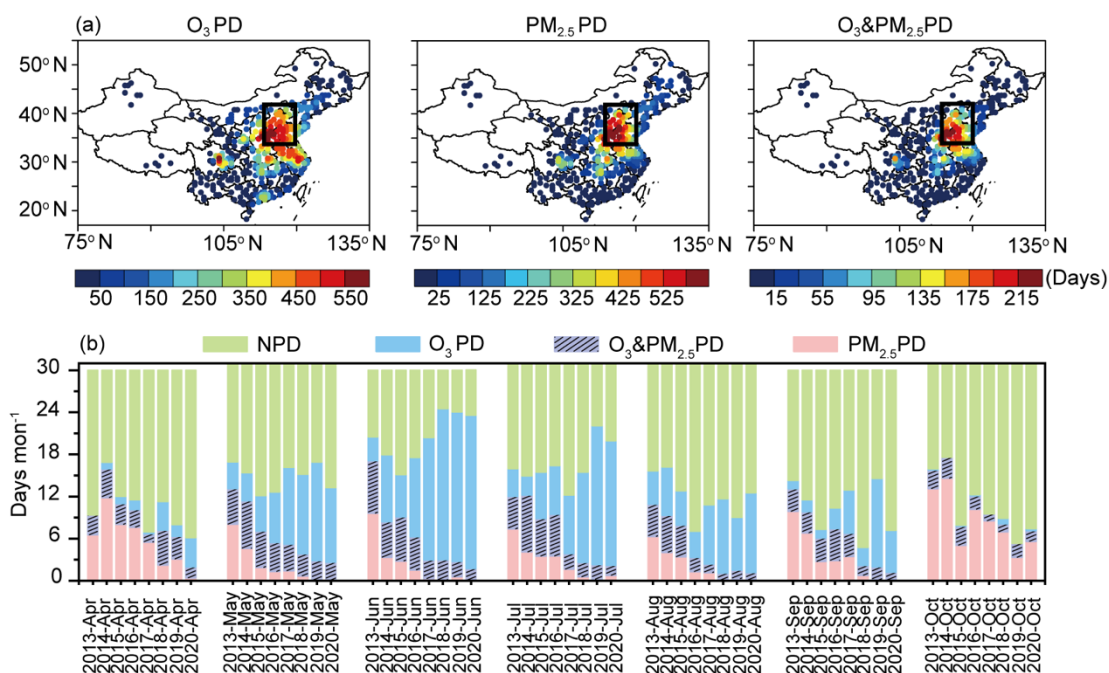

217

### 218 **3. Results**

#### 219 **3.1 Observed polluted days by O<sub>3</sub> and PM<sub>2.5</sub>**

220 Figure 1a shows the spatial distributions of observed numbers of O<sub>3</sub>PD,  
221 PM<sub>2.5</sub>PD, and O<sub>3</sub>&PM<sub>2.5</sub>PD summed over the warm seasons (April-October) of 2013-  
222 2020. The spatial distributions of polluted days in each year are shown in Fig. S1. The  
223 numbers of O<sub>3</sub>PD, PM<sub>2.5</sub>PD, and O<sub>3</sub>&PM<sub>2.5</sub>PD were high in BTH, which were,  
224 respectively, 524.3 344.6, and 128.1 days from observations, as the values were  
225 averaged over all sites in BTH. The high numbers of O<sub>3</sub>PD, PM<sub>2.5</sub>PD, and  
226 O<sub>3</sub>&PM<sub>2.5</sub>PD in BTH were associated with the highest anthropogenic emissions (NO<sub>x</sub>  
227 and NMVOCs) in this region (Dang et al., 2021).

228 Figure 1b shows the numbers of days averaged over all sites in BTH for non-  
229 polluted days (NPD, MDA8 O<sub>3</sub> < 80 ppb and PM<sub>2.5</sub> < 75 µg m<sup>-3</sup>), O<sub>3</sub>PD,  
230 O<sub>3</sub>&PM<sub>2.5</sub>PD, and PM<sub>2.5</sub>PD in each month of warm seasons from 2013 to 2020. O<sub>3</sub>PD  
231 and O<sub>3</sub>&PM<sub>2.5</sub>PD mainly occurred in May, June, and July, while PM<sub>2.5</sub>PD mainly  
232 appeared in April and October. The monthly numbers of O<sub>3</sub>&PM<sub>2.5</sub>PD (PM<sub>2.5</sub>PD)  
233 declined from 2013 to 2020, with the fastest drop in June, from 7.5 (17.1) days in  
234 June 2013 to 1.8 (1.8) days in June 2020. On the contrary, the numbers of O<sub>3</sub>PD kept  
235 increasing, especially in June, from 10.9 days in June 2013 to 23.6 days in June 2020.  
236 The reductions in O<sub>3</sub>&PM<sub>2.5</sub>PD were associated with the large reductions in PM<sub>2.5</sub>  
237 since the implementation of the Clean Air Action in 2013.

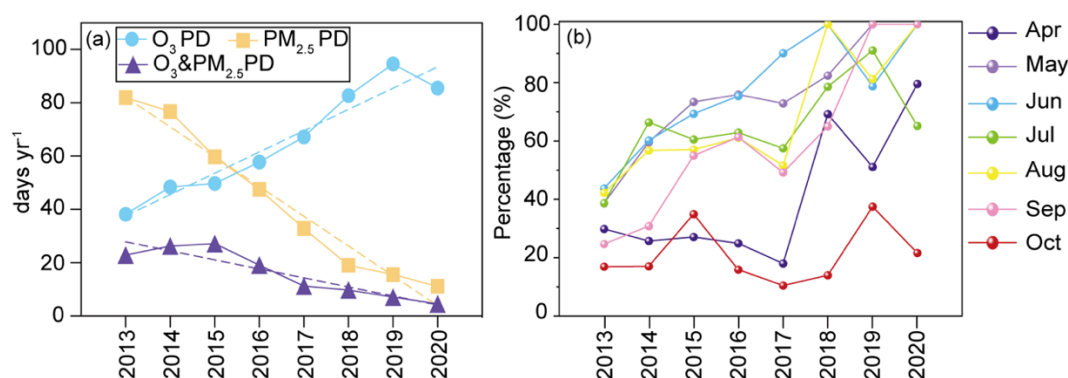

238

239 **Figure 1.** (a) Spatial distributions of observed numbers of O<sub>3</sub>PD, PM<sub>2.5</sub>PD, and  
 240 O<sub>3</sub>&PM<sub>2.5</sub>PD summed over April-October of 2013-2020. The solid black rectangle  
 241 indicates the BTH region. (b) The observed numbers of NPD (non-polluted days,  
 242 green), O<sub>3</sub>PD (blue + purple with slashes), O<sub>3</sub>&PM<sub>2.5</sub>PD (purple with slashes), and  
 243 PM<sub>2.5</sub>PD (pink + purple with slashes) averaged over all sites in BTH from April to  
 244 October in 2013 to 2020.

245 Figure 2a shows the linear trends of observed O<sub>3</sub>PD, PM<sub>2.5</sub>PD, and O<sub>3</sub>&PM<sub>2.5</sub>PD  
 246 in warm seasons of 2013-2020 averaged over the BTH. O<sub>3</sub>PD showed an upward  
 247 trend of 7.9 days yr<sup>-1</sup> from 2013 to 2020. However, the numbers of PM<sub>2.5</sub>PD and  
 248 O<sub>3</sub>&PM<sub>2.5</sub>PD decreased over 2013-2020, with linear trends of -11.2 and -3.4 days yr<sup>-1</sup>,  
 249 respectively. Figure 2b shows the changes in percentage of O<sub>3</sub>&PM<sub>2.5</sub>PD in PM<sub>2.5</sub>PD  
 250 from 2013 to 2020 for each month. It should be noted that, when PM<sub>2.5</sub>PD occurred,  
 251 the proportions of O<sub>3</sub>&PM<sub>2.5</sub>PD had an upward trend from 2013 to 2020. In May,  
 252 June, August, and September of 2020, the proportions of O<sub>3</sub>&PM<sub>2.5</sub>PD in PM<sub>2.5</sub>PD  
 253 reached 100%, indicating that PM<sub>2.5</sub> pollution was accompanied by O<sub>3</sub> pollution in

254 recent years.

255

256 **Figure 2.** (a) The trends of observed O<sub>3</sub>PD, PM<sub>2.5</sub>PD, and O<sub>3</sub>&PM<sub>2.5</sub>PD in warm  
257 seasons from 2013 to 2020 averaged over all sites in BTH. The blue, yellow and purple  
258 solid lines (dashed lines) represent the numbers (liner trend) of O<sub>3</sub>PD, PM<sub>2.5</sub>PD, and  
259 O<sub>3</sub>&PM<sub>2.5</sub>PD, respectively. (b) The percentage of O<sub>3</sub>&PM<sub>2.5</sub>PD in PM<sub>2.5</sub>PD for April

260 to October in 2013 to 2020. The polluted days were averaged over all sites in BTH.

261

## 262 3.2 Simulated polluted days and model evaluation

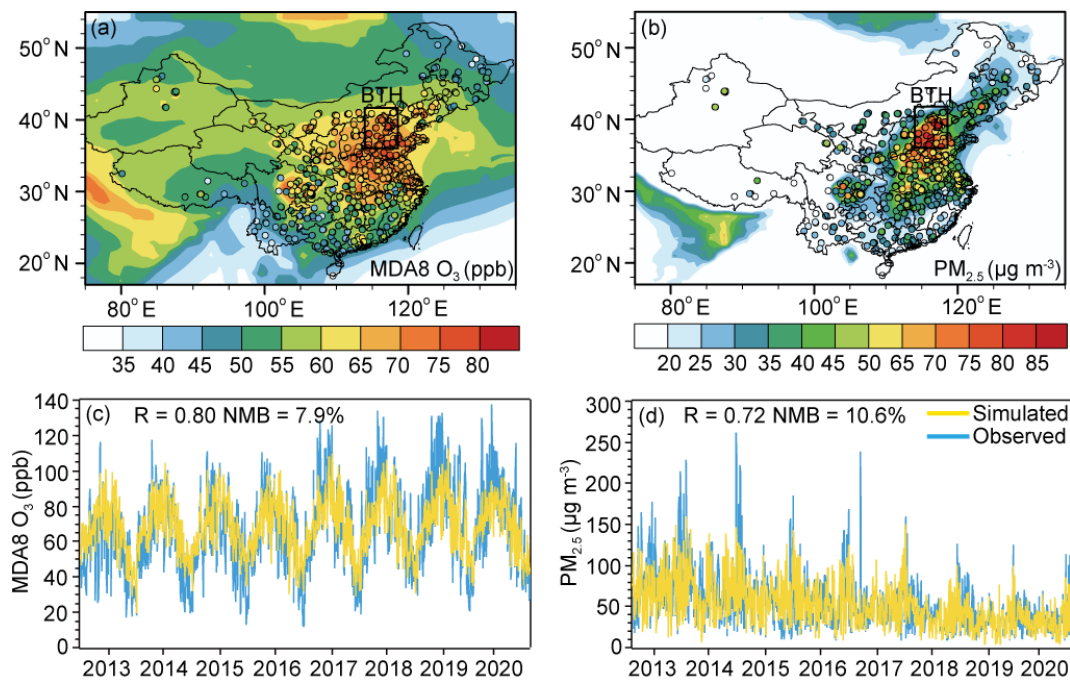

### 263 3.2.1 Simulated surface-layer MDA8 O<sub>3</sub> and PM<sub>2.5</sub> concentrations

264 Figures 3a and 3b show, respectively, the spatial distributions of simulated and  
265 observed surface-layer concentrations of MDA8 O<sub>3</sub> and PM<sub>2.5</sub> in China, as the  
266 concentrations are averaged over the warm seasons (April-October) of 2013-2020.

267 The concentrations of MDA8 O<sub>3</sub> and PM<sub>2.5</sub> were both high in BTH. Averaged over  
268 BTH and the studied time period, the observed concentrations of MDA8 O<sub>3</sub> and PM<sub>2.5</sub>  
269 were 58.1 ppb and 60.3  $\mu\text{g m}^{-3}$ , respectively, while the simulated values were 68.0 ppb  
270 and 61.1  $\mu\text{g m}^{-3}$ , respectively. Figures 3c and 3d compare the time series of observed  
271 and simulated daily MDA8 O<sub>3</sub> and PM<sub>2.5</sub> concentrations averaged over the BTH. The  
272 simulated daily concentrations of MDA8 O<sub>3</sub> (PM<sub>2.5</sub>) in eight warm seasons have a  
273 normalized mean bias (NMB) of 7.9% (10.6%). The model generally captures the  
274 daily variations (peaks and troughs) in the observed MDA8 O<sub>3</sub> and PM<sub>2.5</sub>

275 concentrations, with R values of 0.80 and 0.72, respectively. It should be noted that  
 276 mineral dust and sea-salt aerosols were not considered in this study, because they are  
 277 not the major aerosol components in China and the concentrations are generally low  
 278 based on previous measurements (Xuan et al., 2000; Ye et al., 2003; Duan et al., 2006;  
 279 Zhao et al., 2013). However, excluding dust and sea salt may lead to low biases in  
 280 simulated PM<sub>2.5</sub> concentrations.

281 Due to the lack of the publicly accessible long-term observations of PM<sub>2.5</sub>  
 282 components in China, we compared the simulated SO<sub>2</sub> and NO<sub>2</sub> (precursors for SO<sub>4</sub><sup>2-</sup>  
 283 and NO<sub>3</sub>) with observations from CNEMC in Fig. S2. The simulated daily mean  
 284 concentrations of NO<sub>2</sub> (SO<sub>2</sub>) agree well with the observations from CNEMC with R  
 285 of 0.82 (0.78) and MB of -14.9% (9.3%).

286  
 287 **Figure 3.** Spatial distributions of simulated (shades) and observed (CNEMC, dots)  
 288 surface-layer concentrations of (a) MDA8 O<sub>3</sub> (ppb) and (b) PM<sub>2.5</sub> (μg m<sup>-3</sup>) averaged  
 289 over the eight warm seasons (April to October, 2013–2020). The solid black rectangle  
 290 in (a) and (b) indicates the BTH region. Simulated and observed daily concentrations

291 of surface-layer (c) MDA8 O<sub>3</sub> and (d) PM<sub>2.5</sub> averaged over BTH. The correlation  
292 coefficient (R) and normalized mean bias (NMB) are also shown for (c) and (d).

293  $NMB = (\sum_{i=1}^N (M_i - O_i) / \sum_{i=1}^N (O_i)) \times 100\%$ , where  $O_i$  and  $M_i$  are the observed and  
294 simulated concentrations, respectively,  $i$  refers to the  $i^{th}$  day, and  $N$  is the total number  
295 of days.

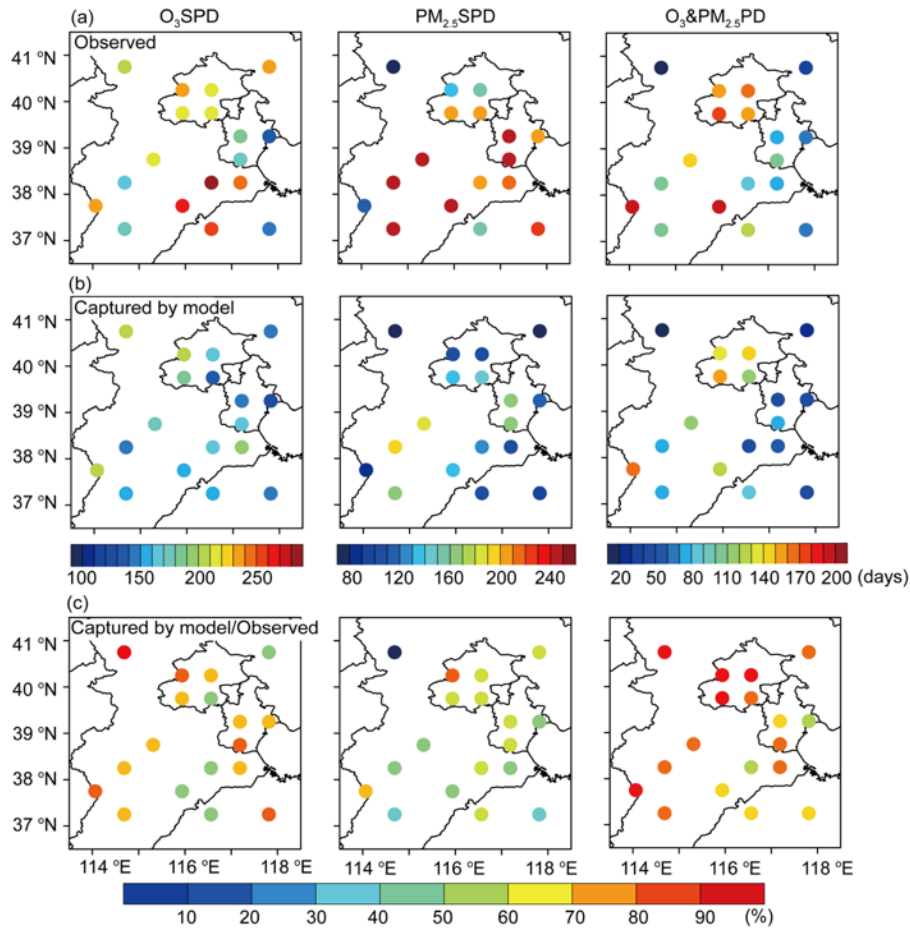

### 296 **3.2.2 Simulated O<sub>3</sub>PD, PM<sub>2.5</sub>PD, and O<sub>3</sub>&PM<sub>2.5</sub>PD**

297 Figure S3 shows the capability of the model in capturing the polluted days.  
298 Although the GEOS-Chem model well reproduces the spatial distributions of observed  
299 MDA8 O<sub>3</sub> and PM<sub>2.5</sub> concentrations, it underestimates the numbers of O<sub>3</sub>PD, PM<sub>2.5</sub>PD,  
300 and O<sub>3</sub>&PM<sub>2.5</sub>PD because of the model's deficiency in capturing the peak  
301 concentrations of air pollutants. Such deficiency was also reported in previous studies  
302 that used the GEOS-Chem model or the weather Research and Forecasting with  
303 Chemistry (WFR-chem) model (Zhang et al., 2016; Ni et al., 2018; Gong and Liao,  
304 2019; Dang and Liao, 2019). Therefore, to identify O<sub>3</sub>PD, PM<sub>2.5</sub>PD, and O<sub>3</sub>&PM<sub>2.5</sub>PD  
305 using model results, we utilized lower thresholds by considering the NMBs of simulated  
306 MDA8 O<sub>3</sub> and PM<sub>2.5</sub> concentrations in each of 18 grids of BTH. Taking the grid of  
307 Beijing as an example, simulated MDA8 O<sub>3</sub> and PM<sub>2.5</sub> had NMBs of -22.0% and -  
308 26.9%, respectively, as the simulated concentrations were compared with observations  
309 for days with observed concentrations higher than the national air quality standards over  
310 the warm seasons of 2013-2020. We then adjusted the threshold of O<sub>3</sub>PD in this grid to  
311 be 62.4 ppb (80 ppb×78%) and that of PM<sub>2.5</sub>PD to be 54.8 μg m<sup>-3</sup> (75 μg m<sup>-3</sup>×73.1%).  
312 These adjusted thresholds were also used to identify O<sub>3</sub>&PM<sub>2.5</sub>PD. Such approach was  
313 also used in previous studies to better capture the pollution events based on the  
314 simulations (Dang and Liao, 2019; Gong and Liao, 2019). With the adjusted thresholds,  
315 56-93% of the observed O<sub>3</sub>PD, PM<sub>2.5</sub>PD, and O<sub>3</sub>&PM<sub>2.5</sub>PD can be captured by the

316 model (Fig. S3e).

### 317 **3.2.3 Simulated O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD**

318 Since O<sub>3</sub>PD or PM<sub>2.5</sub>PD encompasses O<sub>3</sub>&PM<sub>2.5</sub>PD, we further define O<sub>3</sub> single  
319 pollution days (hereafter called “O<sub>3</sub>SPD”, which is to exclude O<sub>3</sub>&PM<sub>2.5</sub>PD from O<sub>3</sub>PD)  
320 and PM<sub>2.5</sub> single pollution days (hereafter called “PM<sub>2.5</sub>SPD”, which is to exclude  
321 O<sub>3</sub>&PM<sub>2.5</sub>PD from PM<sub>2.5</sub>PD) for the purpose of obtaining the characteristics of  
322 different polluted days. Figures 4a and 4b show, respectively, the spatial distributions  
323 of numbers of O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD from observations and from the  
324 GEOS-Chem model using the adjusted thresholds. Considering the total of polluted  
325 days in 18 grids in BTH, observed O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD were,  
326 respectively, 3937, 3698, and 2024 days, in which 75.0% (2954/3937), 58.1%  
327 (2148/3698), and 79.7% (1614/2024) were captured by observation and simulation  
328 simultaneously (Fig. 4c). In addition, the numbers of observed and captured O<sub>3</sub>SPD,  
329 PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD in each month are shown in Fig. S4. The model has a  
330 fairly good capability of capturing the observed polluted days in each month.

331

332 **Figure 4.** Spatial distributions of (a) observed numbers of O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and  
 333 O<sub>3</sub>&PM<sub>2.5</sub>PD, (b) numbers of polluted days that were observed and also captured by  
 334 the GEOS-Chem model with adjusted thresholds, and (c) percentages of observed  
 335 polluted days that were captured by the model with adjusted thresholds. The values  
 336 were calculated for the warm months (April to October) of 2013-2020.

337

### 338 3.3 Chemical characteristics of polluted days by O<sub>3</sub> and PM<sub>2.5</sub>

339 In this section, to investigate the chemical characteristics of O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD  
 340 and O<sub>3</sub>&PM<sub>2.5</sub>PD, we present first the simulated atmospheric oxidants in 3.3.1, and  
 341 then show the simulated surface concentrations and vertical profiles of PM<sub>2.5</sub> and  
 342 MDA8 O<sub>3</sub> in 3.3.2 and 3.3.3, respectively, followed by the process analysis in 3.3.4.  
 343 The observed AOD values to verify the model results are presented in 3.3.5.

### 344 **3.3.1 Atmospheric oxidants of O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD**

345 Figure 5 shows the boxplots of daily concentrations of hydroxyl radical (OH) and  
346 total oxidant ( $O_x = O_3 + NO_2$ ) from the model for days of O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and  
347 O<sub>3</sub>&PM<sub>2.5</sub>PD that were observed and also captured by the model (samples in Fig. 4b)  
348 in the warm seasons of 2013-2020 in 18 grids of BTH. The levels of OH and  $O_x$   
349 characterize the atmospheric oxidation capacity, following Hu et al. (2020) and Chan  
350 et al. (2017). The concentrations of OH were the highest in O<sub>3</sub>SPD, with an averaged  
351 value of  $2.8 \times 10^6$  molec cm<sup>-3</sup>, followed by that in O<sub>3</sub>&PM<sub>2.5</sub>PD ( $2.0 \times 10^6$  molec cm<sup>-3</sup>)  
352 and in PM<sub>2.5</sub>SPD ( $1.0 \times 10^6$  molec cm<sup>-3</sup>). Due to the lack of publicly accessible  
353 observations of OH in BTH, we compare the simulated OH concentrations with  
354 observations reported in the literature (Table S1). The simulated OH concentrations  
355 agree closely with the observed values. In Wangdu of BTH, while the observed daily  
356 maximum OH concentrations in summer of 2014 were in the range of  $5\text{-}15 \times 10^6$  molec  
357 cm<sup>-3</sup> (Tan et al., 2016), the simulated OH concentrations in the same time period in this  
358 work were  $3.7\text{-}9.5 \times 10^6$  molec cm<sup>-3</sup>. In Beijing in summer of 2017, the observed daily  
359 mean OH concentration was  $5.8 \times 10^6$  molec cm<sup>-3</sup> (Woodward et al., 2020) and our  
360 simulated value was  $2.4 \times 10^6$  molec cm<sup>-3</sup>.

361 The mean values of  $O_x$  were, respectively, 178.7, 118.1, and 184.1  $\mu\text{g m}^{-3}$  in  
362 O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD, indicating that the atmospheric oxidation  
363 capacity was strong in O<sub>3</sub>&PM<sub>2.5</sub>PD, which favored the production of secondary  
364 components of PM<sub>2.5</sub>. Figure 5 also shows sulfur oxidation ratio (SOR,  $n\text{-SO}_4^{2-} / (n\text{-SO}_4^{2-}$   
365  $+ n\text{-SO}_2)$ , where  $n\text{-SO}_4^{2-}$  and  $n\text{-SO}_2$  are the concentrations of  $\text{SO}_4^{2-}$  and  $\text{SO}_2$ ,  
366 respectively) and nitrogen oxidation ratio (NOR,  $n\text{-NO}_3^- / (n\text{-NO}_3^- + n\text{-NO}_2)$ , where  $n\text{-NO}_3^-$   
367  $\text{NO}_3^-$  and  $n\text{-NO}_2$  are the concentrations of  $\text{NO}_3^-$  and  $\text{NO}_2$ , respectively). SOR and NOR  
368 are measures of the conversion degrees of sulfur and nitrogen, respectively (Zhu et al.,

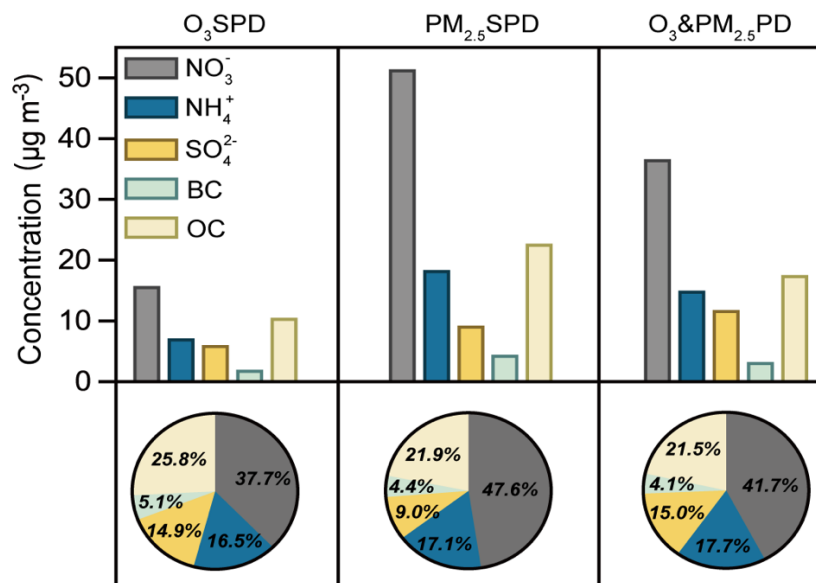

369 2019). In O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD, the averaged values of SOR were  
 370 50.0%, 36.7%, and 49.7%, and those of NOR were 55.4%, 70.0%, and 70.2%,  
 371 respectively. The high SOR and NOR in O<sub>3</sub>&PM<sub>2.5</sub>PD indicated the strong formation  
 372 of SO<sub>4</sub><sup>2-</sup> and NO<sub>3</sub><sup>-</sup> that were promoted by high atmospheric oxidation capacity. The  
 373 monthly variations of OH, O<sub>x</sub>, and SOR were similar (Fig. 5), with the highest values  
 374 in summer, owing to the high temperature that promoted high concentrations of  
 375 oxidants and SOR. It is interesting that SOR and O<sub>x</sub> values were higher in O<sub>3</sub>&PM<sub>2.5</sub>PD  
 376 than in O<sub>3</sub>SPD or in PM<sub>2.5</sub>SPD during May-August. Similarly, NOR values were higher  
 377 in O<sub>3</sub>&PM<sub>2.5</sub>PD than in O<sub>3</sub>SPD or in PM<sub>2.5</sub>SPD in May and July-September. Overall,  
 378 the O<sub>3</sub>&PM<sub>2.5</sub>PD occurred with high levels of atmospheric oxidants, SOR, and NOR,  
 379 leading to combined increases in O<sub>3</sub> and PM<sub>2.5</sub> concentrations.

380  
 381 **Figure 5.** The boxplots of surface-layer hydroxyl radical (OH, molec cm<sup>-3</sup>), total  
 382 oxidant (O<sub>x</sub>, µg m<sup>-3</sup>), sulfur oxidation ratio (SOR, %), nitrogen oxidation ratio  
 383 (NOR, %) for model-captured O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD in 18 grids of  
 384 BTH in the months of April to October from 2013 to 2020. The whiskers represent the  
 385 standard deviation, the black line represents the mean value of the samples.

386 **3.3.2 Surface-layer concentrations of PM<sub>2.5</sub> components in O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and**  
 387 **O<sub>3</sub>&PM<sub>2.5</sub>PD**

388 The simulated concentrations of PM<sub>2.5</sub> components (NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, SO<sub>4</sub><sup>2-</sup>, BC, and  
 389 OC, averaged over 18 grids of BTH are shown in Fig. 6 for days of O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD,  
 390 and O<sub>3</sub>&PM<sub>2.5</sub>PD in the warm seasons of 2013-2020 that were observed and also  
 391 captured by the model. While the mean concentrations of NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, BC, and OC,  
 392 were all the highest in PM<sub>2.5</sub>SPD, SO<sub>4</sub><sup>2-</sup> concentration was the highest in O<sub>3</sub>&PM<sub>2.5</sub>PD.  
 393 In O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD, the mean concentrations of SO<sub>4</sub><sup>2-</sup> were 6.2,  
 394 9.4, and 11.97 μg m<sup>-3</sup>, respectively, and the percentages of SO<sub>4</sub><sup>2-</sup> in PM<sub>2.5</sub> were 14.9%,  
 395 9.0%, and 15.0%, respectively. In July and August, the concentrations of SO<sub>4</sub><sup>2-</sup> and  
 396 MDA8 O<sub>3</sub> in O<sub>3</sub>&PM<sub>2.5</sub>PD were the highest compared with those in O<sub>3</sub>SPD and  
 397 PM<sub>2.5</sub>SPD (Fig. S5).

398  
 399 **Figure 6.** The concentrations of PM<sub>2.5</sub> components (μg m<sup>-3</sup>) and percentages of PM<sub>2.5</sub>  
 400 components (%) at the surface for NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, SO<sub>4</sub><sup>2-</sup>, BC, and OC. The values were  
 401 averaged over the model-captured O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD in the months  
 402 of April to October of 2013-2020 in BTH.

403 Figure 7 presents the hourly concentrations of NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, SO<sub>4</sub><sup>2-</sup>, BC, OC, and O<sub>3</sub>  
 404 for model-captured O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD over all 18 grids of BTH in

405 the warm seasons from 2013-2020. Concentrations of  $\text{NO}_3^-$  and  $\text{NH}_4^+$  had similarities  
406 in diurnal variations, all of which reached the highest values in the early morning (5:00  
407 local time (LT) in  $\text{O}_3\text{SPD}$  and  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$ , 7:00-8:00 LT in  $\text{PM}_{2.5}\text{SPD}$ ) and had the  
408 lowest values in the late afternoon (18:00 LT in  $\text{O}_3\text{SPD}$  and  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$ , 16:00 LT in  
409  $\text{PM}_{2.5}\text{SPD}$ ). Concentrations of BC and OC peaked at the same time as those of  $\text{NO}_3^-$   
410 and  $\text{NH}_4^+$  and had the lowest values at 15:00 LT in  $\text{O}_3\text{SPD}$ ,  $\text{PM}_{2.5}\text{SPD}$ , and  
411  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$ . The diurnal variations in  $\text{NO}_3^-$ ,  $\text{NH}_4^+$ , BC, OC reflected the diurnal  
412 variations in PBLH (shown in Fig. S6), which generally reached their highest  
413 concentrations before the sudden uplift of PBLH in the early morning (times for uplift  
414 of PBLH: 6:00 LT in  $\text{O}_3\text{SPD}$  and  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$ , 7:00 LT in  $\text{PM}_{2.5}\text{SPD}$ ). Compared to  
415  $\text{O}_3\text{SPD}$  and  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$ , the PBLH of  $\text{PM}_{2.5}\text{SPD}$  was lower and uplifted one hour  
416 later, which was more favorable for the accumulation of aerosols. During the daytime,  
417 PBLH in  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$  was between  $\text{O}_3\text{SPD}$  and  $\text{PM}_{2.5}\text{SPD}$ .

418 It is worth noting that the diurnal variations of  $\text{SO}_4^{2-}$  were different from those of  
419 other aerosol species, with the highest values at 20:00, 9:00, and 16:00 LT in  $\text{O}_3\text{SPD}$ ,  
420  $\text{PM}_{2.5}\text{SPD}$ , and  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$ , respectively, and the lowest values in early morning and  
421 night (5:00 LT in  $\text{O}_3\text{SPD}$  and  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$ , 23:00 LT in  $\text{PM}_{2.5}\text{SPD}$ ). For the diurnal  
422 variation of  $\text{O}_3$ , the highest values occurred during the daytime (16:00 LT in  $\text{O}_3\text{SPD}$   
423 and  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$ , 15:00 LT in  $\text{PM}_{2.5}\text{SPD}$ ) and the lowest values appeared at 5:00 LT  
424 in all the cases. Therefore, in  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$ , the time of the highest value of  $\text{SO}_4^{2-}$  was  
425 the same as that of  $\text{O}_3$ , indicating that  $\text{SO}_4^{2-}$  and  $\text{O}_3$  were produced synergistically  
426 during the daytime with strong atmospheric oxidation.

427

428 **Figure 7.** The hourly concentrations of  $\text{NO}_3^-$ ,  $\text{NH}_4^+$ ,  $\text{SO}_4^{2-}$ , BC, OC, and  $\text{O}_3$  averaged  
 429 over the model-captured  $\text{O}_3\text{SPD}$ ,  $\text{PM}_{2.5}\text{SPD}$ , and  $\text{O}_3 \& \text{PM}_{2.5}\text{PD}$  in BTH in the months  
 430 of April to October of 2013-2020.

431 **3.3.3 Vertical distributions of  $\text{O}_3$  and  $\text{PM}_{2.5}$  in  $\text{O}_3\text{SPD}$ ,  $\text{PM}_{2.5}\text{SPD}$ , and**  
 432  **$\text{O}_3\&\text{PM}_{2.5}\text{PD}$**

433 The simulated vertical distributions of  $\text{O}_3$  and  $\text{PM}_{2.5}$  averaged over the 18 grids of  
 434 BTH and the  $\text{O}_3\text{SPD}$ ,  $\text{PM}_{2.5}\text{SPD}$ , and  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$  in warm seasons of 2013-2020 are  
 435 shown in Fig. 8. The vertical distribution of  $\text{O}_3$  in  $\text{O}_3\text{SPD}$  was similar to that in  
 436  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$  (Fig. 8a). In these two cases, concentrations of  $\text{O}_3$  increased from the  
 437 surface to about 975 hPa, remained high between 975 and 819 hPa, and decreased with  
 438 altitude between 819 and 663 hPa. Although the magnitudes of  $\text{O}_3$  were close at the  
 439 surface (61.9 ppb in  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$  and 58.1 ppb in  $\text{O}_3\text{SPD}$ ), the concentration of  $\text{O}_3$

440 averaged over 975 and 819 hPa was 10.4% higher in O<sub>3</sub>&PM<sub>2.5</sub>PD than in O<sub>3</sub>SPD,  
 441 which was a very unique feature of O<sub>3</sub>&PM<sub>2.5</sub>PD. For the case of PM<sub>2.5</sub>SPD, the  
 442 concentrations of O<sub>3</sub> were the lowest among the three cases and increased gently with  
 443 altitude above 975 hPa.

444 Figure 8b shows the vertical distributions of PM<sub>2.5</sub> components. In all the cases,  
 445 PM<sub>2.5</sub> concentrations were the highest at the surface, and decreased with altitude from  
 446 the surface to 975 hPa. However, concentrations of PM<sub>2.5</sub> were quite stable between  
 447 975 and 819 hPa for O<sub>3</sub>SPD (about 36.4 μg m<sup>-3</sup>) and O<sub>3</sub>&PM<sub>2.5</sub>PD (about 58.1 μg m<sup>-3</sup>),  
 448 corresponding to the stable O<sub>3</sub> levels at these altitudes in these two cases (Fig. 8a). For  
 449 PM<sub>2.5</sub>SPD, while PM<sub>2.5</sub> concentration at the surface was the highest among the three  
 450 cases, it decreased rapidly between 975 and 819 hPa. The averaged PM<sub>2.5</sub> concentration  
 451 between 975 and 819 hPa was 52.4 μg m<sup>-3</sup> in PM<sub>2.5</sub>SPD, which was lower than that in  
 452 O<sub>3</sub>&PM<sub>2.5</sub>PD.

453

454 **Figure 8.** The vertical distributions of (a) concentrations of O<sub>3</sub> (ppb) and (b) PM<sub>2.5</sub>

455 components (μg m<sup>-3</sup>) of NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, SO<sub>4</sub><sup>2-</sup>, BC, OC averaged over the model-

456 captured O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD in BTH in the months of April to

457 October of 2013-2020.

458 To further investigate the differences in vertical profiles of NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, SO<sub>4</sub><sup>2-</sup>, BC,

459 OC, and PM<sub>2.5</sub> in O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD, the ratios of concentration at  
 460 975 hPa to that at the surface as well as the concentration at 819 hPa to that at 975 hPa  
 461 are shown in Table 1. The concentration of PM<sub>2.5</sub> decreased largely, with the ratio of  
 462 PM<sub>2.5</sub>(975 hPa) / PM<sub>2.5</sub>(1005 hPa) of 0.78 in O<sub>3</sub>&PM<sub>2.5</sub>PD and of 0.74 in PM<sub>2.5</sub>SPD. For each  
 463 of the PM<sub>2.5</sub> components, the ratios near the surface (from 1005 to 975 hPa, gray shaded  
 464 area in Fig. 8) were close in the three types of pollution. While the ratios of NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>,  
 465 BC, OC were in the range of 0.65-0.80, the ratios of SO<sub>4</sub><sup>2-</sup> were about 0.93-0.98,  
 466 indicating that SO<sub>4</sub><sup>2-</sup> concentrations were quite uniform from the surface to 975 hPa in  
 467 all three types of pollution.

468 **Table 1.** The ratios at 975 and 1005 hPa (gray shaded area in Fig. 8) and at 819 and  
 469 975 hPa (red frame in Fig. 8) of NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, SO<sub>4</sub><sup>2-</sup>, BC, OC, and PM<sub>2.5</sub> in O<sub>3</sub>SPD,  
 470 PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD in BTH region.

		NO <sub>3</sub> <sup>-</sup>	NH <sub>4</sub> <sup>+</sup>	SO <sub>4</sub> <sup>2-</sup>	BC	OC	PM <sub>2.5</sub>
Conc <sub>819 hPa</sub> / Conc <sub>975 hPa</sub>	O <sub>3</sub> SPD	0.95	0.90	0.85	0.73	0.73	0.86
	PM <sub>2.5</sub> SPD	0.64	0.68	0.81	0.64	0.63	0.67
	O <sub>3</sub> &PM <sub>2.5</sub> PD	0.94	0.91	0.87	0.79	0.77	0.89
Conc <sub>975hPa</sub> / Conc <sub>1005 hPa</sub>	O <sub>3</sub> SPD	0.65	0.77	0.96	0.69	0.70	0.74
	PM <sub>2.5</sub> SPD	0.72	0.76	0.93	0.67	0.65	0.73
	O <sub>3</sub> &PM <sub>2.5</sub> PD	0.72	0.80	0.98	0.76	0.73	0.78

471

472 In the upper layers (975-819 hPa, red rectangle in Fig. 8), the changes in  
 473 concentrations of pollutants with altitude in PM<sub>2.5</sub>SPD were quite different from those  
 474 in O<sub>3</sub>&PM<sub>2.5</sub>PD and O<sub>3</sub>SPD. The decline of PM<sub>2.5</sub> from 975 to 819 hPa was slow in  
 475 O<sub>3</sub>&PM<sub>2.5</sub>PD (PM<sub>2.5</sub>(819 hPa) /PM<sub>2.5</sub>(975 hPa) = 0.89) and O<sub>3</sub>SPD (0.86) and fast in

476 PM<sub>2.5</sub>SPD (0.67). Considering that the variation of BC with altitude was mainly driven  
477 by meteorology (Sun et al., 2020), the vertical variations of other components that  
478 differed significantly from BC indicated the influences of chemical processes. In  
479 PM<sub>2.5</sub>SPD, NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, OC had about the same ratio as BC (0.64) (with large decreases  
480 with height), except for SO<sub>4</sub><sup>2-</sup> concentration that had a ratio of 0.81. In O<sub>3</sub>&PM<sub>2.5</sub>PD,  
481 the ratios of NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, SO<sub>4</sub><sup>2-</sup> were, 0.94, 0.91, 0.87, respectively, which were much  
482 higher than the value of BC (0.79), indicating NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, SO<sub>4</sub><sup>2-</sup> were quite uniform  
483 in the layers of 975-819 hPa with the influence of chemical processes, which will be  
484 discussed further in Sect. 3.3.4 below.

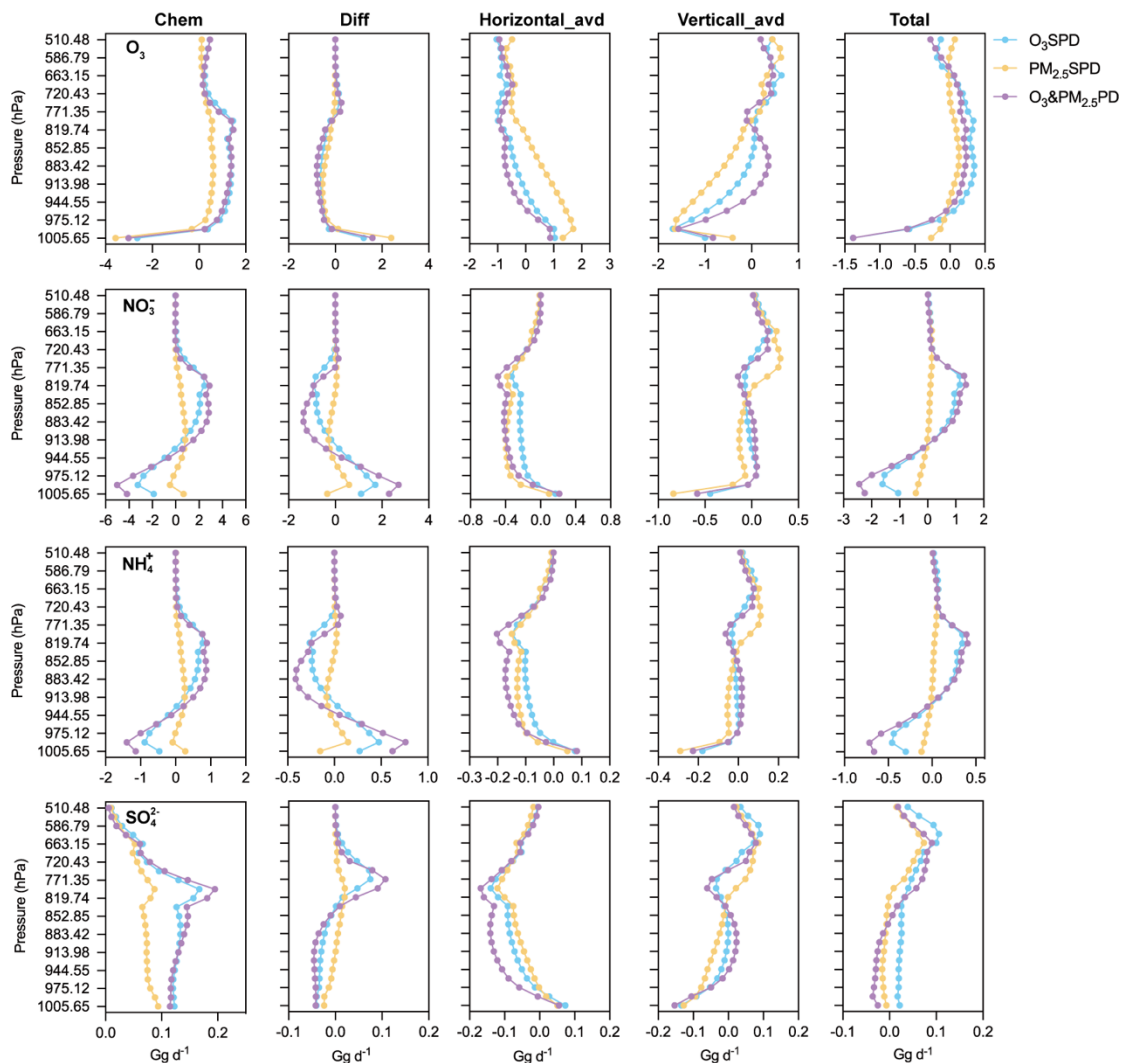

#### 485 **3.3.4 Process analyses for O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD**

486 The process analysis (PA) is applied to identify the relative importance of  
487 atmospheric processes in the three types of pollution. Figure 9 shows the net changes  
488 in O<sub>3</sub>, NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, SO<sub>4</sub><sup>2-</sup> by the processes of chemical production (Chem), horizontal  
489 advection (Horizontal\_adv), vertical advection (Vertical\_adv), and diffusion (Diff,  
490 vertical PBL mixing process) in the GEOS-Chem model, as well as the total of all these  
491 processes (i.e., Chem + Diff + Horizontal\_adv + Vertical\_adv) in O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD,  
492 and O<sub>3</sub>&PM<sub>2.5</sub>PD.

493 For O<sub>3</sub>, the net changes of O<sub>3</sub> by all processes were positive at altitudes of 975-  
494 819 hPa in O<sub>3</sub>&PM<sub>2.5</sub>PD and O<sub>3</sub>SPD, in which Chem had the largest positive  
495 contribution (about 1.5 Gg d<sup>-1</sup>), indicating O<sub>3</sub> is chemically produced at these layers.  
496 For NO<sub>3</sub><sup>-</sup> and NH<sub>4</sub><sup>+</sup>, the nets of all processes increased mass concentrations at 913-819  
497 hPa in O<sub>3</sub>&PM<sub>2.5</sub>PD and O<sub>3</sub>SPD, in which Chem and Vertical\_adv were positive and  
498 Chem had the largest positive contribution. The vertical profiles of Chem were similar  
499 for NO<sub>3</sub><sup>-</sup> and NH<sub>4</sub><sup>+</sup>, both of which had the largest positive values at 913-819 hPa ( 2.83  
500 Gg d<sup>-1</sup> for NO<sub>3</sub><sup>-</sup> and 0.88 Gg d<sup>-1</sup> for NH<sub>4</sub><sup>+</sup>), leading to higher concentrations of NO<sub>3</sub><sup>-</sup>

501 and  $\text{NH}_4^+$  in  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$  than in  $\text{O}_3\text{SPD}$  and  $\text{PM}_{2.5}\text{SPD}$ . Chem and Diff of  $\text{SO}_4^{2-}$   
 502 were different from those of  $\text{NO}_3^-$  and  $\text{NH}_4^+$ . For  $\text{SO}_4^{2-}$ , Chem was positive from the  
 503 surface to 510 hPa with a peak around 819 hPa, and Diff was positive at 819-771 hPa  
 504 but negative from 819 hPa to the surface, which resulted in the uniform  $\text{SO}_4^{2-}$  profile  
 505 as shown in Fig. 8. Chem for  $\text{SO}_4^{2-}$  was the highest around 819 hPa in  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$ ,  
 506 which was related to the strong liquid-phase chemical formation of  $\text{SO}_4^{2-}$  (Fig. S7). In  
 507 addition to Chem, Vertical\_avd also had positive contributions to the net changes in  $\text{O}_3$ ,  
 508  $\text{NO}_3^-$ ,  $\text{NH}_4^+$ , and  $\text{SO}_4^{2-}$  at 944-819 hPa. Vertical\_avd was negative at 819 hPa and  
 509 positive between 944 to 819 hPa, implying that the pollutants were transported from  
 510 819 hPa to 944 hPa in  $\text{O}_3\&\text{PM}_{2.5}\text{PD}$ .

511

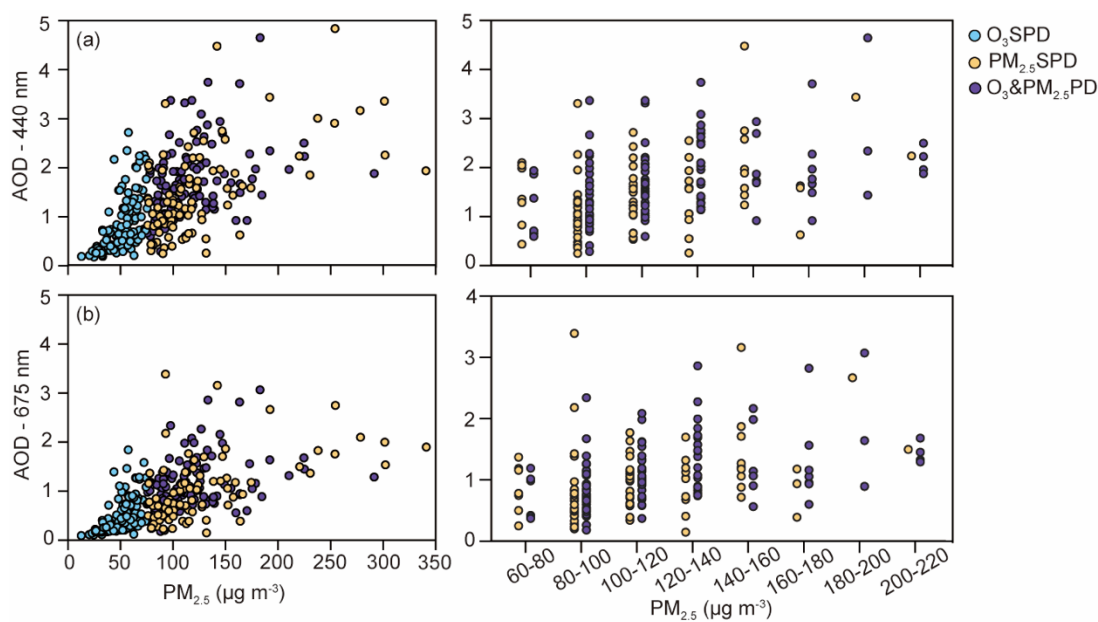

512 **Figure 9.** The vertical profiles of net changes in  $O_3$ ,  $NO_3^-$ ,  $NH_4^+$ , and  $SO_4^{2-}$  ( $Gg\ d^{-1}$ )  
513 over BTH by each and total of processes. The values were averaged over the model-  
514 captured regional  $O_3$ SPD,  $PM_{2.5}$ SPD, and  $O_3$ & $PM_{2.5}$ PD in April-October of 2013-  
515 2020.

516 Overall,  $NO_3^-$ ,  $NH_4^+$ , and  $SO_4^{2-}$  all had larger chemical productions at 913-819  
517 hPa in  $O_3$ & $PM_{2.5}$ PD compared to those in  $O_3$ SPD and  $PM_{2.5}$ SPD, accompanied by  
518 strong vertical transport from 819 hPa to near the surface, resulting in the quite uniform  
519 vertical profiles at 975-819 hPa in  $O_3$ & $PM_{2.5}$ PD. In addition, the vertical profiles of net  
520 changes in  $PM_{2.5}$  over BTH are shown in Fig. S8 for these three cases. Since  $NO_3^-$ ,  
521  $NH_4^+$ , and  $SO_4^{2-}$  were the major components of  $PM_{2.5}$ , the PA of  $PM_{2.5}$  is similar to that  
522 of each component.

### 523 **3.3.5 Observed AOD in $O_3$ SPD, $PM_{2.5}$ SPD, and $O_3$ & $PM_{2.5}$ PD**

524 To try to support the model result that  $O_3$ & $PM_{2.5}$ PD had more uniform vertical  
525 profile than  $PM_{2.5}$ SPD from the surface to 819 hPa altitude, we present the scatter plots  
526 of observed AOD (at 440 nm and 675 nm) versus observed  $PM_{2.5}$  concentrations in  
527  $O_3$ SPD,  $PM_{2.5}$ SPD, and  $O_3$ & $PM_{2.5}$ PD in Fig. 10. AERONET observations of AOD  
528 from 2013 to 2020 are available at three sites in BTH (that is, Beijing (39.97°N, 116.38°  
529 E), Beijing-CAMS (39.93°N, 116.31°E), Xianghe (39.75°N, 116.96°E)). At Beijing  
530 (39.97°N, 116.38°E), AOD (440nm and 675nm) increased with  $PM_{2.5}$  concentration in  
531 all three types of pollution. However, under the same levels of surface  $PM_{2.5}$   
532 concentration, AOD values in  $O_3$ & $PM_{2.5}$ PD were higher than in  $PM_{2.5}$ SPD, implying  
533 that the column burdens of aerosols were generally higher in  $O_3$ & $PM_{2.5}$ PD than in  
534  $PM_{2.5}$ SPD, which may support the unique vertical distribution of  $PM_{2.5}$  in  $O_3$ & $PM_{2.5}$ PD  
535 shown in Fig. 8b. The scatter plots at Beijing-CAMS and Xianghe sites are similar and

536 are shown in Fig. S9.

537

538 **Figure 10.** The scatterplots of (a) AOD (440 nm) and (b) AOD (675 nm) versus  
539 observed PM<sub>2.5</sub> concentrations in O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD in Beijing  
540 (39.97°N, 116.38°E) in April-October of 2013-2020.

541

### 542 3.4 Meteorological conditions for O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD over BTH

543 Figure 11 shows the vertical profiles of RH, T, and OMEGA for O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD,  
544 and O<sub>3</sub>&PM<sub>2.5</sub>PD captured by the model over BTH in the months of April to October  
545 from 2013-2020. It should be noted that O<sub>3</sub>&PM<sub>2.5</sub>PD had an unique vertical  
546 distribution of RH. Near the surface, the values of RH in O<sub>3</sub>&PM<sub>2.5</sub>PD were between  
547 those in O<sub>3</sub>SPD and PM<sub>2.5</sub>SPD. However, in the upper layers (883-771 hPa),  
548 O<sub>3</sub>&PM<sub>2.5</sub>PD had the highest RH among the three cases with a peak value of 58.2%.  
549 As a result, the strongest aqueous chemical production of SO<sub>4</sub><sup>2-</sup> (aqueous oxidation of  
550 SO<sub>2</sub> by H<sub>2</sub>O<sub>2</sub>) occurred in O<sub>3</sub>&PM<sub>2.5</sub>PD around 819 to 771 hPa (Fig. S7). The vertical  
551 profiles of temperature were similar in the three types of pollution, with the lowest  
552 temperature in PM<sub>2.5</sub>SPD. The vertical profiles of OMEGA were different in the three

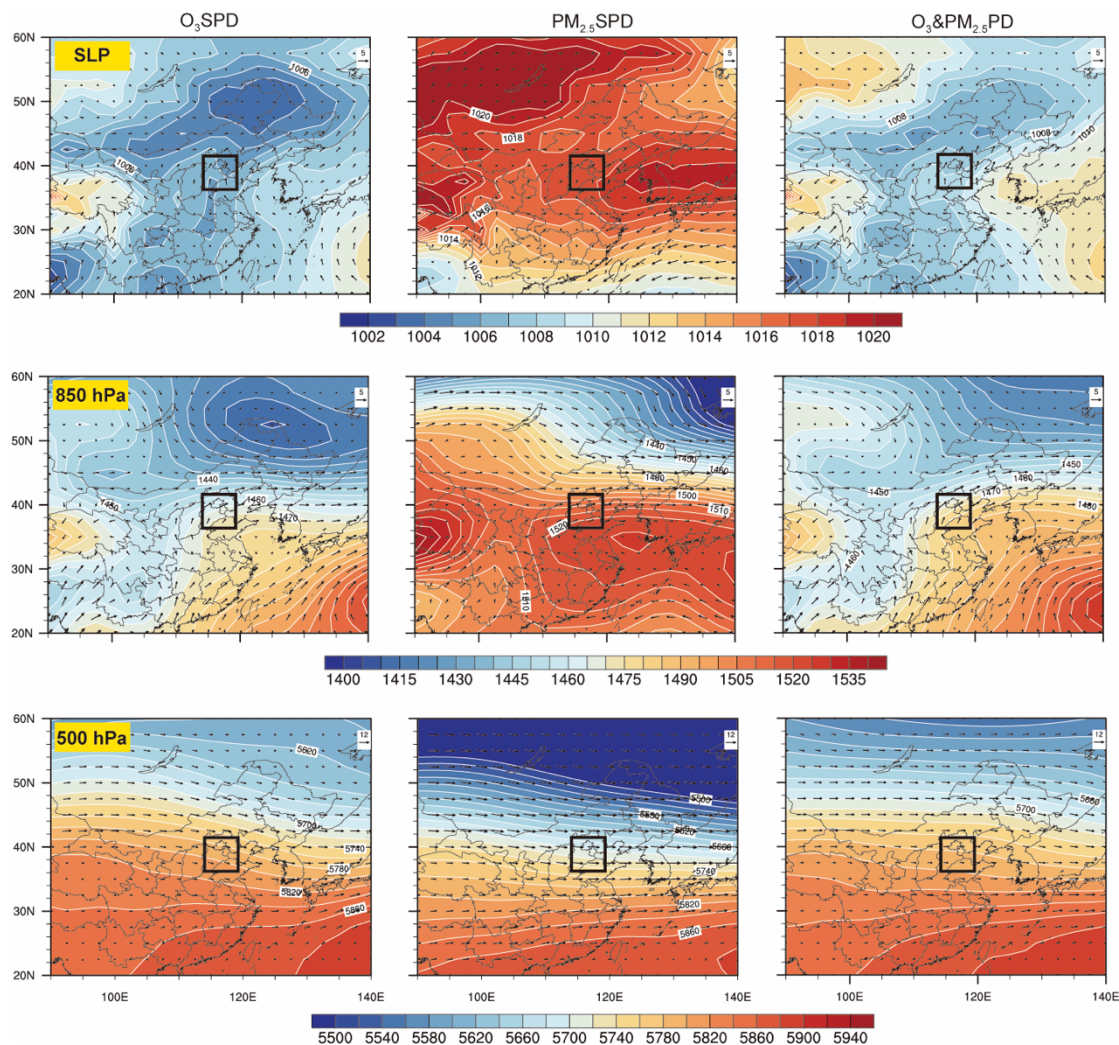

553 cases. In O<sub>3</sub>SPD and O<sub>3</sub>&PM<sub>2.5</sub>PD, OMEGA had positive values around 819 hPa,  
 554 indicating a strong sinking airflow, leading to a downward transport of pollutants.  
 555 Under O<sub>3</sub>&PM<sub>2.5</sub>PD, the average values of PBLH and SWGDN were 946.1 m and  
 556 257.2 W m<sup>-2</sup>, respectively, which were higher (lower) than those in PM<sub>2.5</sub>SPD (O<sub>3</sub>SPD)  
 557 (Fig. S10).

558  
 559 **Figure 11.** The vertical profiles of RH (%), T (°C), and OMEGA (Pa s<sup>-1</sup>) averaged over  
 560 BTH and over the model-captured regional O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD in in  
 561 April-October of 2013-2020.

562 Figure 12 shows the composited weather patterns for regional O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD,  
 563 and O<sub>3</sub>&PM<sub>2.5</sub>PD (over 50% cities in the BTH experienced the pollution) that were  
 564 captured by the model in April-October of 2013-2020. The weather patterns of  
 565 O<sub>3</sub>&PM<sub>2.5</sub>PD were similar to some extent to those of O<sub>3</sub>SPD but were quite different  
 566 from those of PM<sub>2.5</sub>SPD. In O<sub>3</sub>&PM<sub>2.5</sub>PD, the BTH region was controlled by westerlies  
 567 and an anomalous high-pressure system at 500 hPa (Figure S11). At 850 hPa, BTH was  
 568 at the west boundary of an anomalous anticyclone, and the associated strong anomalous  
 569 southerlies at 850 hPa brought moist air to BTH (Fig. S12 and S13), resulting in a high  
 570 RH that was beneficial to the aqueous chemical production of SO<sub>4</sub><sup>2-</sup> in O<sub>3</sub>&PM<sub>2.5</sub>PD.  
 571 In O<sub>3</sub>SPD, BTH was under the influence of the high pressure ridge of the Western  
 572 Pacific Subtropical High (WPSH) at 850 hPa. Besides, the Northeast Cold Vortex was  
 573 located to the southwest of BTH at 850 hPa in O<sub>3</sub>SPD, leading to dry and warm  
 574 conditions, which was favorable for the formation of O<sub>3</sub>. In PM<sub>2.5</sub>SPD, the BTH region

575 was under the influence of both the continental high and the WPSH at 850 hPa. At the  
 576 surface, BTH was under the influence of a uniform high pressure with very weak winds  
 577 and hence stagnate atmosphere, which was conducive to the accumulation of PM<sub>2.5</sub>.

578  
 579 **Figure 12.** Composites of wind field ( $\text{m s}^{-1}$ ) with SLP (sea level pressure) and with  
 580 geopotential height at 850 hPa and 500 hPa for regional O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and  
 581 O<sub>3</sub>&PM<sub>2.5</sub>PD that were captured by the model in April-October of 2013-2020. The  
 582 solid black rectangle indicates BTH region.

583

#### 584 4. Conclusions

585 We used the observed hourly concentrations of O<sub>3</sub> and PM<sub>2.5</sub> from CNEMC and  
 586 the model results from the nested-grid version of the GEOS-Chem model to examine

587 the chemical and physical characteristics of the co-polluted days by O<sub>3</sub> and PM<sub>2.5</sub>  
588 (O<sub>3</sub>&PM<sub>2.5</sub>PD) over the BTH region for eight warm seasons (April-October) from  
589 2013 to 2020. The characteristic of O<sub>3</sub>&PM<sub>2.5</sub>PD were compared with those of the  
590 polluted days by O<sub>3</sub> alone (O<sub>3</sub>SPD) and by PM<sub>2.5</sub> alone (PM<sub>2.5</sub>SPD). In April-October  
591 of 2013-2020, the observed O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD were 2954, 2148,  
592 and 1614 days, respectively, in which 75.0% (2954/3937), 58.1% (2148/3698), and  
593 79.7% (1614/2024) were captured by the GEOS-Chem model, respectively. We  
594 carried out composited analyses of the chemical and physical characteristics for  
595 O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD, and O<sub>3</sub>&PM<sub>2.5</sub>PD by using the samples (days) captured by both  
596 the observations and the model.

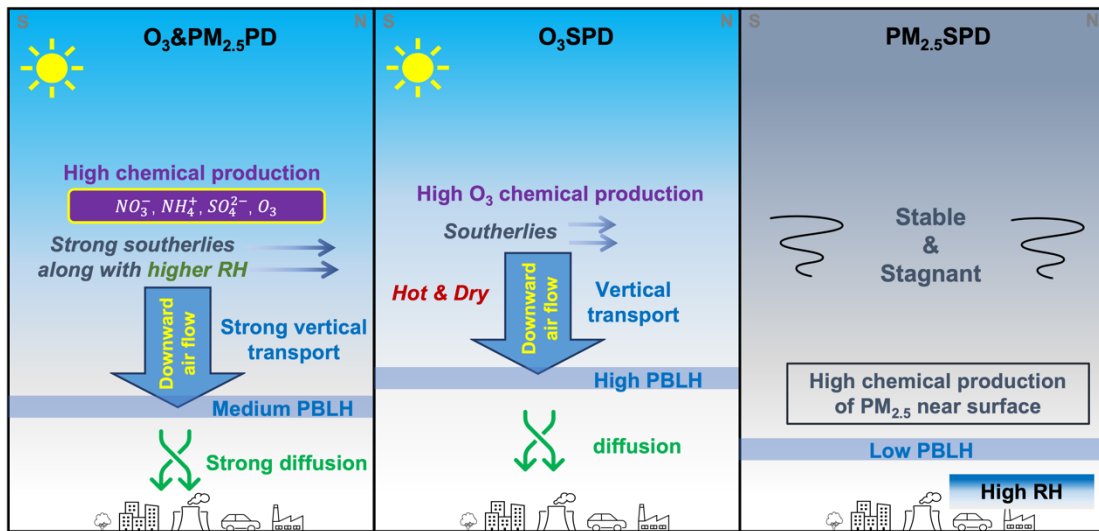

597 The chemical characteristics of O<sub>3</sub>&PM<sub>2.5</sub>PD were found to be different from  
598 those of O<sub>3</sub>SPD, PM<sub>2.5</sub>SPD at the surface. O<sub>3</sub>&PM<sub>2.5</sub>PD occurred with high levels of  
599 atmospheric oxidants (high OH and O<sub>x</sub>), with higher SOR and NOR compared to those  
600 in O<sub>3</sub>SPD and PM<sub>2.5</sub>SPD, leading to high concentrations of both O<sub>3</sub> and PM<sub>2.5</sub>. At the  
601 surface, the composited concentrations of NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, BC, and OC were the highest in  
602 PM<sub>2.5</sub>SPD, while the composited concentration of SO<sub>4</sub><sup>2-</sup> was the highest in  
603 O<sub>3</sub>&PM<sub>2.5</sub>PD. There was a strong formation of SO<sub>4</sub><sup>2-</sup> during the daytime in  
604 O<sub>3</sub>&PM<sub>2.5</sub>PD in the oxidative atmosphere.

605 We also found unique features of the vertical distributions of O<sub>3</sub> and PM<sub>2.5</sub> in  
606 O<sub>3</sub>&PM<sub>2.5</sub>PD. Concentrations of PM<sub>2.5</sub> were stable and high between 975 and 819 hPa  
607 in O<sub>3</sub>&PM<sub>2.5</sub>PD, unlike those in PM<sub>2.5</sub>SPD that decreased rapidly with the altitude. In  
608 O<sub>3</sub>&PM<sub>2.5</sub>PD, the vertical profiles of NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, and SO<sub>4</sub><sup>2-</sup> were quite uniform at  
609 975-819 hPa, corresponding to the stable O<sub>3</sub> concentrations at these altitudes. The  
610 process analysis (PA) showed that NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, and SO<sub>4</sub><sup>2-</sup> all had larger chemical  
611 productions at altitudes of 913-819 hPa in O<sub>3</sub>&PM<sub>2.5</sub>PD compared to those in O<sub>3</sub>SPD

612 and PM<sub>2.5</sub>SPD. The chemical production of SO<sub>4</sub><sup>2-</sup> had large positive values from the  
613 surface to about 500 hPa. The Vertical\_avd also had positive contributions to the net  
614 changes in O<sub>3</sub>, NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, and SO<sub>4</sub><sup>2-</sup> at 944-819 hPa in O<sub>3</sub>&PM<sub>2.5</sub>PD. Therefore, the  
615 strong chemical productions at 913-819 hPa accompanied by the downward transport  
616 resulted in the quite uniform vertical profiles at 975-819 hPa in O<sub>3</sub>&PM<sub>2.5</sub>PD.

617 Figure 13 summarizes the chemical and physical characteristics in O<sub>3</sub>&PM<sub>2.5</sub>PD,  
618 O<sub>3</sub>SPD, and PM<sub>2.5</sub>SPD in the BTH region. In O<sub>3</sub>&PM<sub>2.5</sub>PD, the strong chemical  
619 productions of O<sub>3</sub>, NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, and SO<sub>4</sub><sup>2-</sup> occurred at high altitudes of 913-819 hPa  
620 where RH was high, and the accompanied downward airflow caused the stable  
621 concentrations at 944-819 hPa. The composited PBLH in O<sub>3</sub>&PM<sub>2.5</sub>PD was about 946.1  
622 m, and the strong mixed diffusion underneath the PBLH led to high concentrations of  
623 pollutants at the ground level. In contrast, O<sub>3</sub>SPD occurred in hot and dry atmosphere  
624 with composited PBLH of 1073.5 m. Strong O<sub>3</sub> chemical production occurred around  
625 819 hPa, and O<sub>3</sub> was then transported to the surface by downward air flow. The  
626 atmosphere was stable and stagnate when PM<sub>2.5</sub>SPD occurred, with the lowest PBLH  
627 of 681.8 m. High RH (high chemical formation of PM<sub>2.5</sub>) and the accumulation of  
628 aerosols led to the highest surface-layer PM<sub>2.5</sub> in PM<sub>2.5</sub>SPD.

629 To summarize, O<sub>3</sub>&PM<sub>2.5</sub>PD were characterized by high O<sub>x</sub>, SOR, and NOR,  
630 uniform vertical profiles at 975-819 hPa, which were caused by an anomalous high-  
631 pressure system at 500 hPa, strong southerlies and high RH at 850 hPa. Meteorological  
632 parameters around 850 hPa promoted strong chemical production of secondary aerosols  
633 and downward transport, resulting in the unique vertical profiles and high surface  
634 concentrations in O<sub>3</sub>&PM<sub>2.5</sub>PD.
