12 **Abstract**

13 Renoxification is the process of recycling of NO₃⁻/HNO₃ into NO_x under
14 illumination, which is mostly ascribed to the photolysis of nitrate. TiO₂, a typical
15 mineral dust component, can play its photocatalytic role in “renoxification” process
16 due to NO₃ radical formed, and we define this process as “photocatalytic
17 renoxification”. Formaldehyde (HCHO), the most abundant carbonyl compound in
18 the atmosphere, may participate in the renoxification of nitrate-doped TiO₂ particles.
19 In this study, we established an environmental chamber reaction system with the
20 presence of HCHO and nitrate-doped TiO₂. The direct photolyses of both nitrate and
21 NO₃ radical were excluded by adjusting the illumination wavelength, so as to explore
22 the effect of HCHO on the “photocatalytic renoxification”. It is found that NO_x

Formatted: Indent: First line: 2 ch

23 concentration can reach up to more than 100 ppb for nitrate-doped TiO₂ particles,
24 while almost no NO_x was generated in the absence of HCHO. Nitrate type, relative
25 humidity and HCHO concentration were found to influence NO_x release. Adsorbed
26 HCHO may react with nitrate radicals through hydrogen abstraction to form adsorbed
27 HNO₃ on the surface, which is responsible for the release of NO_x. The mass
28 generation of NO_x was suggested to via the NO₃⁻-NO₃[·]-HCHO-HNO₃-NO_x pathway,
29 with HCHO and TiO₂ exhibiting a significant synergistic effect. Our proposed
30 reaction mechanism by which HCHO promotes photocatalytic renoxification is
31 helpful for deeply understanding the atmospheric photochemical processes and
32 nitrogen cycling. Renoxification is the recycling of NO₃⁻/HNO₃ into NO_x under
33 illumination; it is promoted by the photocatalysis of TiO₂. Formaldehyde (HCHO),
34 the most abundant carbonyl compound in the atmosphere, may participate in the
35 renoxification of nitrate-doped TiO₂ (NO₃⁻-TiO₂) aerosols. In this study, we
36 established an environmental chamber reaction system under different light sources,
37 excluding direct photolysis of nitrate by adjusting the illumination wavelength, to
38 explore the photocatalytic renoxification process. It is suggested that HCHO and TiO₂
39 have a significant synergistic effect on photocatalytic renoxification via the
40 NO₃⁻-NO₃[·]-HCHO-HNO₃-NO_x pathway. Adsorbed HCHO may react with nitrate
41 radicals through hydrogen abstraction to form HNO₃ on the surface, resulting in the
42 mass generation of NO_x. We found that for 4 wt% NO₃⁻-TiO₂ aerosols (e.g.,
43 KNO₃-TiO₂), the NO_x concentration reached up to 110 ppb, and was 2 orders of
44 magnitude higher than in the absence of HCHO. Nitrate type and contents, relative

45 ~~humidity, and HCHO concentration were found to influence NO_x release. The~~
46 ~~significant synergistic enhancement effect of renoxification affects photochemical~~
47 ~~processes such as atmospheric oxidation and nitrogen cycling on the surfaces of~~
48 ~~particles containing semiconductor oxides, with the participation of hydrogen donor~~
49 ~~organics.~~

51 **1 Introduction**

52 The levels of ozone (O₃) and hydroxyl radicals (\cdot OH) in the troposphere can be
53 promoted by nitrogen oxides (NO_x = NO + NO₂), such that NO_x plays an important
54 role in the formation of secondary aerosols and atmospheric oxidants (Platt et al.,
55 1980; Stemmler et al., 2006; Harris et al., 1982; Finlayson-Pitts and Pitts, 1999). NO_x
56 can be converted into nitric acid (HNO₃) and nitrate (NO₃⁻) through a series of
57 oxidation and hydrolysis reactions and is eventually removed from the atmosphere
58 through subsequent wet or dry deposition (Dentener and Crutzen, 1993; Goodman et
59 al., 2001; Monge et al., 2010; Bedjanian and El Zein, 2012). However, comparisons
60 of observations and modeling results for the marine boundary layer, land, and free
61 troposphere (Read et al., 2008; Lee et al., 2009; Seltzer et al., 2015) have shown
62 underestimation of HNO₃ or NO₃⁻ content, NO_x abundance, and NO_x/HNO₃ ratios,
63 indicating the presence of a new, rapid NO_x circulation pathway (Ye et al., 2016b;
64 Reed et al., 2017). Some researchers have suggested that deposited NO₃⁻ and HNO₃
65 can be recycled back to gas phase NO_x under illumination, via the renoxification
66 process (Schuttlefield et al., 2008; Romer et al., 2018; Bao et al., 2020; Shi et al.,

67 2021). Photolytic renoxification occurs under light with a wavelength of < 350 nm,
68 through the photolysis of $\text{NO}_3^-/\text{HNO}_3$ adsorbed on the solid surface to generate NO_x .
69 Notably, the photolysis of $\text{NO}_3^-/\text{HNO}_3$ is reported to occur at least 2 orders of
70 magnitude faster on different solid surfaces (natural or artificial) or aerosols than in
71 the gas phase (Ye et al., 2016a; Zhou et al., 2003; Baergen and Donaldson, 2013).
72 Several recent studies have shown that renoxification has important atmospheric
73 significance (Deng et al., 2010; Kasibhatla et al., 2018; Romer et al., 2018; Alexander
74 et al., 2020), providing the atmosphere with a new source of photochemically reactive
75 nitrogen species, i.e., HONO or NO_x , resulting in the production of more
76 photooxidants such as O_3 or $\cdot\text{OH}$ (Ye et al., 2017), which further oxidize volatile
77 organic compounds (VOCs), leading to the formation of more chromophores, thereby
78 affecting the photochemical process (Bao et al., 2020).

79 Renoxification processes have recently been observed on different types of
80 atmospheric particles, such as urban grime and mineral dust (Ninneman et al., 2020;
81 Bao et al., 2018; Baergen and Donaldson, 2013; Ndour et al., 2009). Atmospheric
82 titanium dioxide (TiO_2) is mainly derived from windblown mineral dust, with mass
83 mixing ratios ranging from 0.1 to 10% (Chen et al., 2012). TiO_2 is widely used in
84 industrial processes and building exteriors for its favorable physical and chemical
85 properties. Titanium and nitrate ions have been found to coexist in atmospheric
86 particulates in different regions worldwide (Sun et al., 2005; Schwartz-Narbonne et al.,
87 2019). The relative content of TiO_2 and NO_3^- in atmospheric particles varies greatly,
88 and nitrate-coated TiO_2 ($\text{NO}_3^-/\text{TiO}_2$) aerosols containing TiO_2 as the main body can

89 be used to effectively represent particles for sandstorm modeling (Sun et al., 2005;
90 Kim et al., 2012). TiO₂ is a semiconductor metal oxide that can facilitate the
91 photolysis of nitrate and the release of NO_x due to its photocatalytic activity (Ndour et
92 al., 2009; Chen et al., 2012; Verbruggen, 2015; Schwartz-Narbonne et al., 2019).
93 Under ultraviolet (UV) light, TiO₂ generates electron-hole pairs in the conduction and
94 valence bands, respectively (Linsebigler et al., 1995). Nitrate ions adsorbed at the
95 oxide surface react with the photogenerated holes (h⁺) to form nitrate radicals (NO₃·),
96 which are subsequently photolyzed to NO_x, mainly under visible light illumination
97 (Schuttlefield et al., 2008; George et al., 2015; Schwartz-Narbonne et al., 2019). Thus,
98 the renoxification of NO₃⁻ is faster on TiO₂ than on other oxides in mineral dust
99 aerosols such as SiO₂ or Al₂O₃ (Lesko et al., 2015; Ma et al., 2021). In this study, we
100 refer to renoxification involving h⁺ and NO₃⁻ in the reaction as photocatalytic
101 renoxification based on the photocatalytic properties of TiO₂.

102 Many previous studies have focused mainly on particulate nitrate-NO_x
103 photochemical cycling reactions, despite the potential impact of other reactant gases
104 in the atmosphere. Formaldehyde (HCHO), the most abundant carbonyl compound in
105 the atmosphere, which can react at night with NO₃· via hydrogen abstraction reactions
106 to form HNO₃ (Atkinson, 1991). Our previous study showed that the degradation rate
107 of HCHO was faster on NO₃⁻-TiO₂ aerosols than on TiO₂ particles, perhaps as a result
108 of HCHO oxidation by NO₃· (Shang et al., 2017). To date, no studies have reported the
109 effect of HCHO on photocatalytic renoxification. Adsorbed HCHO would react with
110 NO₃· generated on the NO₃⁻-TiO₂ aerosol surface, thus alter the surface nitrogenous

111 species and renoxification process. The present study is the first to explore the
112 combined effect of HCHO and photocatalytic TiO₂ particles on the renoxification of
113 nitrate. The wavelengths of the light sources were adjusted to exclude photolytic
114 renoxification while making photocatalytic renoxification available for better
115 elucidate the reaction mechanism. We investigated the effects of various influential
116 factors including nitrate type, nitrate content, RH, and initial HCHO concentration, to
117 understand the atmospheric renoxification of nitrate in greater detail.

118 **2 Methods**

119 **2.1 Environmental chamber setup**

120 Details of the experimental apparatus and protocol used in the current study have
121 been previously described (Shang et al., 2017). Briefly, the main body of the
122 environmental chamber is a 400 L polyvinyl fluoride (PVF) bag filled with synthetic
123 air (high purity N₂ (99.999%) mixed with high purity O₂ (99.999%) in the ratio of
124 79:21 by volume, Beijing Huatong Jingke Gas Chemical Co.). The chamber is
125 capable of temperature (~293 K) and relative humidity (0.8–70%) control using a
126 water bubbler and air conditioners, respectively. The chamber is equipped with two
127 light sources both with the central wavelength of 365 nm. One is a set of [36 W](#) tube
128 lamps with a main spectrum of 320–400 nm and a small amount of 480–600 nm
129 visible light (Figure S1a). The other is a set of [12 W](#) Light-emitting diode (LED)
130 lamps with a narrow main spectrum of 350–390 nm (Figure S1b). The light intensities
131 for the tube and LED lamp at 365 nm were 300 μW·cm⁻² and 200 μW·cm⁻²,
132 respectively, measured in the middle of the chamber. NO_x concentrations at the outlet

133 of the chamber were monitored by a chemiluminescence NO_x analyzer (ECOTECH,
134 EC9841B). HCHO was generated by thermolysis of paraformaldehyde at 70 °C and
135 detected via acetyl acetone spectrophotometric method using a UV-Vis
136 spectrophotometer (PERSEE, T6) or a fluorescence spectrophotometer (THERMO,
137 Lumina), depending on different initial HCHO concentrations. The particle size
138 distribution was measured by a Scanning Nano Particle Spectrometer (HCT,
139 SNPS-20). Electron Spin Resonance (Nuohai Life Science, MiniScope MS 5000) was
140 used to measure ·OH on the surface of particles. 5,5-dimethyl-1-pyrroline-N-oxide
141 (DPMO, Enzo) was used as the capture agent. 50 μL particle-containing suspension
142 mixed with 50 μL DMPO (concentration of 200 μM) was loaded in a 1 mm capillary.
143 Four 365 nm LED lamps were placed side by side vertically at a distance of about 1
144 cm from the capillary, and the measurement was carried out after 1 min of irradiation.
145 The modulation frequency was 100 kHz, the modulation amplitude was 0.2 mT, the
146 microwave power was 10 mW and the sweep time was 60 s.

147 **2.2 Nitrate-TiO₂ composite samples**

148 In our experiments, two nitrate salts, potassium nitrate (AR, Beijing Chemical
149 Works Co., Ltd) or ammonium nitrate (AR, Beijing Chemical Works Co., Ltd), were
150 complexed with pure TiO₂ (≥ 99.5%, Degussa AG) powder or TiO₂ (1 wt.)/SiO₂
151 mixed powder to prepare NO₃⁻-TiO₂ or NO₃⁻-TiO₂ (1 wt.)/SiO₂ samples. 250 mg
152 TiO₂ was simply mixed in nitrate solutions at the desired mass mixing ratio (with
153 nitrate content of 1 wt.%, 4 wt.%, 20 wt.%, 80 wt.% and 95 wt.%) to obtain a mash.
154 The mash was dried at 90 °C and then ground carefully for 30 min. A series of

155 [samples with different amount of nitrate were prepared and diffuse reflectance fourier](#)
156 [transform infrared spectroscopy \(DRIFTS\) measurements were made to test their](#)
157 [homogeneity. Figure S2 shows DRIFTS spectra of these KNO₃-TiO₂ composites, of](#)
158 [which 1760 cm⁻¹ peak is one of the typical vibrating peaks of nitrate \(Aghazadeh,](#)
159 [2016; Maeda et al., 2011\). Ratio value of peak area from 1730-1790 cm⁻¹ for 1, 4, 32,](#)
160 [80 wt.% composited samples is 1: 4.1: 29.8: 81.6, which is very close to that of](#)
161 [theoretical value, proving that the samples were uniformly mixed. ~~The mash was~~](#)
162 [dried at 90 °C and then ground carefully to ensure a uniform composite of particles.](#)

163 SiO₂ (AR, Xilong Scientific Co., Ltd.) with no optical activity was also chosen for
164 comparison, and samples of KNO₃-SiO₂ and KNO₃-TiO₂(1 wt.%)/SiO₂ samples with
165 a potassium nitrate content of 4 wt.% were prepared. The blank [250 mg](#) TiO₂ sample
166 was solved in pure water with the same procedure as mentioned above. 4 wt.%
167 HNO₃-TiO₂ composite particles were prepared for comparison. Concentrated nitric
168 acid (AR, Beijing Chemical Works Co., Ltd) was diluted to 1 M and [250 mg](#) TiO₂ was
169 added to the nitric acid solution and stirred evenly. A layer of aluminum foil was
170 covered on the surface of the HNO₃-TiO₂ homogenate and dried naturally in the room.
171 After air-drying, follow the same steps above to grind for use. We also selected
172 Arizona Test Dust (ATD, Powder Technology Inc.), whose chemical composition and
173 weight percentage were shown in Table S1, as a substitute of NO₃⁻/TiO₂ to investigate
174 the “photocatalytic renoxification” process of nitrate and the positive effect of HCHO.

175 **2.3 Environmental chamber experiments**

176 [For the chamber operation, we completely evacuated the chamber after every](#)

177 [experiment, then cleaned the chamber walls with deionized water and then dried by](#)
178 [flushing the chamber with ultra-zero air to remove any particles or gases collected on](#)
179 [the chamber walls.](#) The experiments carried out in the environmental chamber can be
180 divided into two categories according to whether HCHO was involved or not. (1) No
181 HCHO involvement in the reaction. The PVF bag was inflated by 260 L synthetic air,
182 and [then 75 mg particles were instantly sprayed into the chamber by a transient](#)
183 [high-pressure airflow. then 75 mg TiO₂ particles were sprayed into PVF bag.](#) As
184 shown in Figure S23, the concentration of [the 4 wt.% KNO₃-TiO₂](#) particles decreased
185 rapidly due to the sedimentation of the larger particles and the electrostatic adsorption
186 of the particles by the environmental chamber. The size distribution [of TiO₂](#) reached
187 stable after about 60 min with the peak particle size was about 120 nm, similar to that
188 of atmospheric particles in some urban areas in China (Wang et al., 2015; Li et al.,
189 2019). [The size distribution could maintain for more than 4 hours, with the number](#)
190 [concentration in the chamber decreased by no more than 5% per hour.](#) (2) With the
191 participation of HCHO. The PVF bag was inflated by 125 L synthetic air, followed by
192 the introduction of HCHO, and then the chamber was filled up with zero air to about
193 250 L. [In order to know the HCHO adsorption before and after the particles'](#)
194 [introduction, we conducted a conditional experiment in the dark. It can be seen from](#)
195 [Figure S4 that it took about 90 min for the concentration of HCHO to reach stable,](#)
196 [and can be sustained. It can be seen from Figure S3 that it took about 60 min for the](#)
197 [HCHO concentration to reach stable.](#) Then, 75 mg TiO₂ or NO₃⁻/TiO₂ powders were
198 introduced [instantly](#) and the concentration of HCHO decreased upon the introduction.

199 It took about ~~another~~ 60 min for HCHO to reach its second adsorption equilibrium,
200 and the concentration of HCHO can be stable for several hours in the dark. Therefore,
201 for the irradiation experiments, the particles were injected at 90 min after HCHO's
202 introduction, and the lamps were turned on at 60 min after the particle's
203 introduction for HCHO concentration to get stable. After the concentrations of both
204 HCHO and aerosol became stable, the lamps were turned on and the concentrations of
205 NO_x were monitored.

206 To determine the background value of NO_x in the reaction system, four blank
207 experiments were carried out under illumination without nitrate: “synthetic air”,
208 “synthetic air + TiO₂”, “synthetic air + HCHO” and “synthetic air + HCHO + TiO₂”.
209 In the blank experiments of “synthetic air” and “synthetic air + TiO₂”, the NO_x
210 concentration remained stable during 180 min illumination, and the concentration
211 change was no more than 0.5 ppb (Figure S45a). Therefore, the environmental
212 chamber, synthetic air and the surface of TiO₂ particles were thought to be relatively
213 clean, and there was no generation and accumulation of NO_x under illumination.
214 When HCHO was introduced into the environmental chamber, NO_x accumulated ~2
215 ppb in 120 min with or without TiO₂ particles (Figure S45b). Compared with the
216 blank experiment results when there was no HCHO, NO_x might come from the
217 generation process of HCHO (impurities in paraformaldehyde). However, considering
218 the high concentration level of NO_x produced in the NO₃⁻-TiO₂ system containing
219 HCHO under the same conditions in this study (see later in Figure 2), the NO_x
220 generated in this blank experiment can be negligible.

221 **3 Results and discussion**

222 **3.1 The positive effect of TiO₂ on the renoxification process**

223 We investigated the photocatalytic role of TiO₂ on renoxification. The light source
224 was two 365 nm tube lamps containing small amounts of 400–600 nm visible light;
225 this setup was suitable for exciting TiO₂ and the photolysis of available nitrate
226 radicals. Raw NO_x data measured in the chamber under dark and illuminated
227 conditions for 4 wt.% KNO₃-SiO₂ and 4 wt.% KNO₃-TiO₂ (1 wt.%)/SiO₂ are shown
228 in Figure 1. The ratio of 1 wt. % TiO₂ to SiO₂ corresponds to their ratio in sand and
229 dust particles. We observed no NO_x in the KNO₃-SiO₂ sample under dark or
230 illumination, indicating very weak direct photolysis of nitrate under our 365 nm
231 tube-lamp illumination conditions. However, when the sample containing TiO₂/SiO₂
232 was illuminated, NO_x continually accumulated in the chamber. This finding confirms
233 that NO_x production arising from photodissociation of NO₃⁻ on TiO₂/SiO₂ was caused
234 by the photocatalytic property of TiO₂ (i.e., photocatalytic renoxification) and was not
235 due to the direct photolysis of NO₃⁻ (photolytic renoxification).

236

237 **Figure 1.** Effect of illumination on the release of NO_x from 4 wt.% KNO₃-SiO₂ and 4
238 wt.% KNO₃-TiO₂(1 wt.%)/SiO₂ at 293 K and 0.8% of relative humidity. 365 nm tube
239 lamps were used during the illumination experiments.

240 TiO₂ can be excited by UV illumination to generate electron-hole pairs, and the
241 h⁺ can react with adsorbed NO₃⁻ to produce NO₃[·] (Ndour et al., 2009). Thus, in the
242 present study, NO₃[·] mainly absorbed visible light emitted from the tube lamps, which
243 was subsequently photolyzed to NO_x through Eqs. (3) and (4) (Wayne et al., 1991),
244 which explains why NO_x was observed in this study. Thus, we demonstrated that TiO₂
245 can be excited at illumination wavelengths of ~365 nm, even when then content was
246 very low, and that NO_x accumulated due to the production and further phytolysis of
247 NO₃[·]. However, the production rate of NO_x was very slow, reaching only 1.3 ppb
248 during 90 min of illumination. This result may have been caused by the blocking
249 effect of K⁺ on NO₃⁻. K⁺ forms ion pairs with NO₃⁻, and electrostatic repulsion
250 between K⁺ and h⁺ prevents NO₃⁻ from combining with h⁺ to generate NO₃[·] to a
251 certain extent, thereby weakening the positive effect of TiO₂ on the renoxification of
252 KNO₃ (Rosseler et al., 2013).

257 **3.2 The synergistic positive effect of TiO₂ and HCHO on the renoxification**
258 **process**

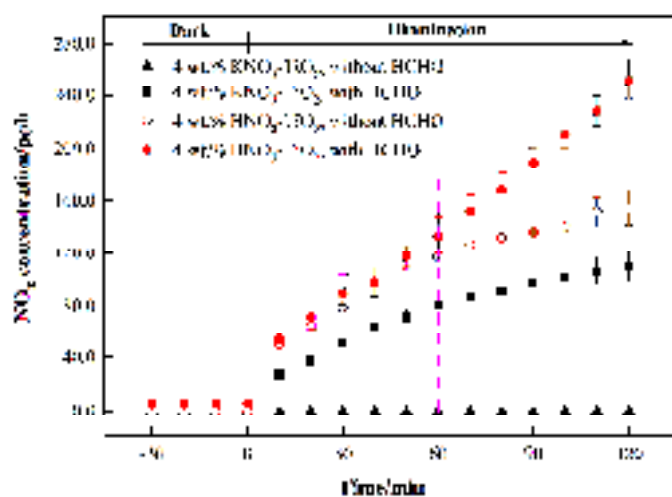

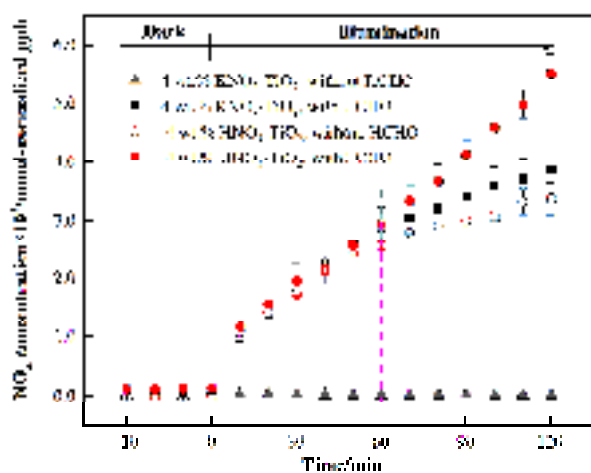

259 LED lamps with a wavelength range of 350–390 nm and no visible light were
260 used to irradiate 4 wt.% KNO₃-TiO₂ without generating NO_x (NO₂ and NO
261 concentrations fluctuate within the error range of the instrument) (Figure S56). TiO₂
262 can be excited under this range of irradiation, producing NO₃ radicals as discussed
263 above. The lack of NO_x generation indicates that neither nitrate photolysis nor
264 NO₃· photolysis occurred under 365 nm LED lamp illumination conditions. In
265 addition, it has been shown that NO₃· photolysis only occurs in visible light (Aldener
266 et al., 2006). Therefore, the LED lamp setup was used in subsequent experiments to
267 exclude the direct photolysis of both KNO₃ and NO₃·, but allow the excitation of TiO₂.
268 This approach allowed us to investigate the process of photocatalytic renoxification
269 caused by HCHO in the presence of photogenerated NO₃·.

270 Atmospheric trace gases can undergo photocatalytic reactions on the surface of
271 TiO₂ (Chen et al., 2012). As the illumination time increased, the concentration of
272 HCHO showed a linear downward trend, which was ~~found to fit consistent with~~
273 zero-order reaction kinetics (Figure S67). The zero-order reaction rate constants of
274 HCHO on TiO₂ and 4 wt.% KNO₃-TiO₂ particles were 9.1×10^{-3} and 1.4×10^{-2} ppm
275 min⁻¹, respectively, which were much higher than that for gaseous HCHO photolysis
276 (Shang et al., 2017). We suggested that the produced NO₃· contributed to the
277 enhanced uptake of HCHO. ~~Therefore, we suggest that NO₃· production contributed~~
278 ~~to enhanced HCHO uptake. In the following study, the effect of HCHO on the~~
279 ~~photocatalytic renoxification of NO₃·-TiO₂ was explored. Future studies should~~
280 ~~explore whether HCHO affects the photocatalytic renoxification of NO₃·-TiO₂.~~

281 Variation in NO_x concentration within the chamber containing nitrate- TiO_2
282 particles with or without HCHO is shown in Figure 2. For [4 wt.% \$\text{KNO}_3\$ - \$\text{TiO}_2\$](#)
283 particles, the NO_x concentration began to increase upon irradiation in the presence of
284 HCHO, reaching [~3861 mmol-normalized ppb \(equivalent to 110 ppb\)](#)~~~110 ppb~~
285 within 120 min. This result indicates that HCHO greatly promoted photocatalytic
286 renoxification of KNO_3 on the surfaces of TiO_2 particles. This reaction process can be
287 divided into two stages: a rapid increase within the first 60 min and a slower increase
288 within the following 60 min, each consistent with zero-order reaction kinetics. The
289 slow stage is due to the photodegradation of HCHO on KNO_3 - TiO_2 aerosols, which
290 led to a decrease in its concentration, gradually weakening the positive effect. NO_x is
291 the sum of NO_2 and NO , both of which showed a two-stage concentration increase
292 [\(Figure S8\)](#). The NO_2 generation rate was nearly 6 times that of NO , as compared to
293 using the zero-order rate constant within 60 min ($1.18 \text{ ppb min}^{-1} \text{ NO}_2$, $R^2 = 0.96$; 0.19
294 $\text{ppb min}^{-1} \text{ NO}$, $R^2 = 0.91$). This burst-like generation of NO_x can be ascribed to the
295 reaction between generated $\text{NO}_3\cdot$ and HCHO via hydrogen abstraction to form
296 adsorbed nitric acid ($\text{HNO}_3(\text{ads})$) on TiO_2 particles. [We measured the pH of water](#)
297 [extracts in \$\text{NO}_3^-\$ - \$\text{TiO}_2\$ systems with and without HCHO. It was found that the pH](#)
298 [decreased by 1.7% for \$\text{KNO}_3\$ - \$\text{TiO}_2\$, suggesting the formation of acidic species such as](#)
299 [\$\text{HNO}_3\(\text{ads}\)\$ in this study.](#) Based on the analysis of the absorption cross section of
300 HNO_3 adsorbed on fused silica surface, the $\text{HNO}_3(\text{ads})$ absorption spectrum has been
301 reported to be red-shifted compared to $\text{HNO}_3(\text{g})$, extending from 350 to 365 nm, with
302 a simultaneous cross-sectional increase (Du and Zhu, 2011). Therefore, $\text{HNO}_3(\text{ads})$

303 was subjected to photolysis to produce NO₂ and HONO (Eqs. (6)-(8)) under the LED
 304 lamp used in this study. A previous study of HNO₃ photolysis on the surface of Pyrex
 305 glass showed that the ratio of the formation rates of photolysis products
 306 ($J_{\text{NO}_x}/J_{(\text{NO}_x+\text{HONO})}$) was > 97% at RH = 0% (Zhou et al., 2003), suggesting that NO_x is
 307 the main gaseous product under dry conditions. Thus, the effect of HONO on product
 308 distribution and NO_x concentration was negligible in this study. Together, these results
 309 suggest that NO₃· and HCHO generate HNO₃(ads) on particle surfaces through
 310 hydrogen abstraction, which contributes to the substantial release of NO_x via
 311 photolysis. This photocatalytic renoxification via the NO₃⁻-NO₃·-HCHO-HNO₃-NO_x
 312 pathway is important considering the high abundance of hydrogen donor organics in
 313 the atmosphere.

318

319

320 **Figure 2.** Effect of formaldehyde on the renoxification processes of different nitrate-
 321 doped particles at 293 K and 0.8% of relative humidity. 365 nm LED lamps were used
 322 during the illumination experiment. The initial concentration of HCHO was about 9
 323 ppm.

324 To demonstrate the proposed HCHO mechanism and the photolysis contribution
 325 of HNO₃ to NO_x, we prepared an HNO₃-TiO₂ sample by directly dissolving TiO₂ into

326 dilute nitric acid. The formation of NO_x on $\text{HNO}_3\text{-TiO}_2$ without HCHO under
327 illumination was obvious ~~and at a rate comparable with (Figure 2), and occurred even~~
328 ~~more rapidly than~~ that on $\text{KNO}_3\text{-TiO}_2$ with HCHO (Figure 2). The renoxification of
329 $\text{HNO}_3\text{-TiO}_2$ particles was further enhanced following the introduction of HCHO. ~~The~~
330 ~~NO_x concentration increased by 250 ppb after 2 h of illumination, which was 2.2~~
331 ~~times faster than the increase in $\text{KNO}_3\text{-TiO}_2$ concentration under the same conditions.~~
332 This ~~is~~ ~~difference is due to the fact~~ ~~because~~ that HNO_3 dissociates on particle
333 surfaces to generate NO_3^- , such that HNO_3 exists on TiO_2 as both $\text{HNO}_3(\text{ads})$ and
334 $\text{NO}_3^-(\text{ads})$. Similarly, $\text{NO}_3^-(\text{ads})$ completed the $\text{NO}_3^- \text{-NO}_3 \cdot \text{-HCHO-HNO}_3 \text{-NO}_x$
335 pathway as described above through the reaction process shown in Eqs. (2) to (8). The
336 rates of NO_x production from $\text{HNO}_3\text{-TiO}_2$ particles with and without HCHO were
337 similar for the first 60 min (Figure 2), mainly due to the direct photolysis of partial
338 $\text{HNO}_3(\text{ads})$. However, after 60 min, NO_x was generated rapidly in the presence of
339 HCHO, perhaps due to the dominant photocatalytic renoxification of $\text{NO}_3^-(\text{ads})$.
340 These findings indicate that HCHO converts NO_3^- on particle surfaces into $\text{HNO}_3(\text{ads})$
341 by reacting with $\text{NO}_3 \cdot$, and then $\text{HNO}_3(\text{ads})$ photolyzes at a faster rate to generate
342 NO_x , allowing HCHO to enhance the formation of NO_x . Overall, the photocatalytic
343 renoxification of $\text{NO}_3^- \text{-TiO}_2$ particles affects atmospheric oxidation and the nitrogen
344 cycle, and the presence of HCHO further enhances this impact.

345 Photocatalytic renoxification reaction occurs on the surfaces of mineral dust due
346 to the presence of semiconductor oxides with photocatalytic activity such as TiO_2
347 (Ndour et al., 2009). ~~In order to confirm this, we synthesized nitrate with inert SiO_2~~

348 [as a comparison. It can be seen from Figure S9 that no NO₂ formation was observed](#)
349 [whether HCHO was present or not, indicating that photocatalytically active particle](#)
350 [TiO₂ is critical to the photocatalytic renoxification process. Furthermore, a kind of](#)
351 [commercial mineral dust ATD was selected](#)~~In this study, we selected the commercial~~
352 ~~mineral dust ATD~~ to study the effects of HCHO on this process. We detected ·OH in
353 irradiated pure TiO₂ and ATD samples using electron spin resonance (ESR) technique,
354 and found that for ATD samples, the peak intensity of ·OH generation was 40% that
355 of TiO₂ samples (Figure S810). ·OH originates in the reaction of h⁺ with surface
356 adsorbed water (Ahmed et al., 2014). ATD contains semiconductor oxides such as
357 TiO₂ and Fe₂O₃, and is thought to exhibit photocatalytic properties affecting the
358 renoxification of nitrate. The NO₃⁻ content of ATD is 4 × 10¹⁷ molecules m⁻², which is
359 ~0.25 wt.% of the total mass (Huang et al., 2015; Jiyeon et al., 2017). The NO_x
360 concentration changes observed in the environmental chamber demonstrated that
361 HCHO promoted the renoxification of ATD particles (Figure S911). This result
362 suggests that mineral dust containing photocatalytic semiconductor oxides such as
363 TiO₂, Fe₂O₃, and ZnO can greatly promote the conversion of granular nitrate to NO_x
364 in the presence of HCHO.

365

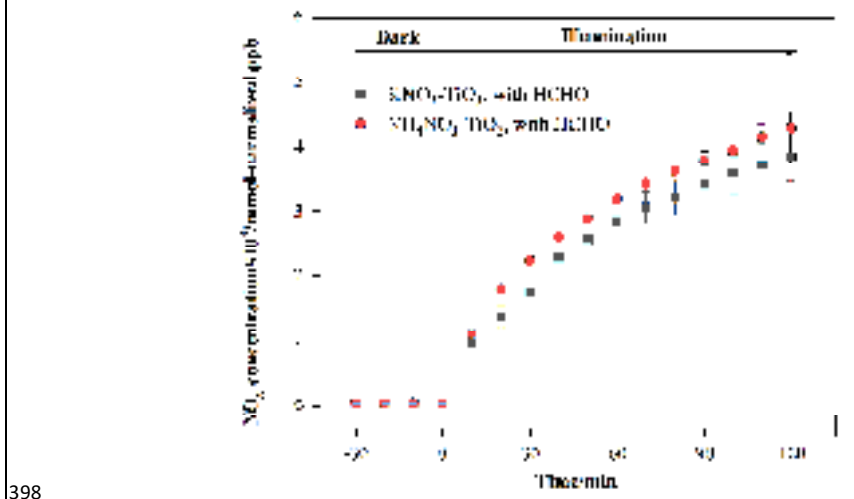

366 **3.3 Influential factors on the photocatalytic renoxification process**

367 **3.3.1 The influence of nitrate type**

368 As discussed above, HNO₃ and KNO₃ undergo different renoxification processes on
369 the surface of TiO₂ under the same illumination conditions, suggesting that cations

370 bound to NO_3^- significantly affect NO_x production. Different types of cations coexist
371 with nitrate ions in atmospheric particulate matter, among which ammonium ions
372 (NH_4^+) are important water-soluble ions that can be higher in content than K^+ in urban
373 fine particulate matter (Zhou et al., 2016; Tang et al., 2021; Wang et al., 2021),
374 especially in heavily polluted cities.(Tian et al., 2020) Equal amounts of 4 wt.%
375 $\text{NH}_4\text{NO}_3\text{-TiO}_2$ particles were introduced into the chamber and illuminated under the
376 same conditions. [Similar as Figure 2, millimole normalized ppb was used in order to](#)
377 [compare the amount of \$\text{NO}_x\$ release for different kinds of nitrate with same percentage](#)
378 [weight. It can be seen that](#) HCHO had a much stronger positive effect on the release
379 of NO_x over $\text{NH}_4\text{NO}_3\text{-TiO}_2$ particles (Figure 3), which may be ascribed to NH_4^+ .
380 Combined with the results of $\text{NH}_4\text{NO}_3\text{-TiO}_2$ and $\text{KNO}_3\text{-TiO}_2$ particles, it seems that
381 the affinity rather than electrostatic repulsion should be the primary effect of cations
382 on the production of NO_x . On substrates without photocatalytic activity such as SiO_2
383 and Al_2O_3 , NH_4NO_3 cannot generate NO_x ,(Ma et al., 2021) such that NO_x production
384 depends on the effect of TiO_2 . The h^+ generated by TiO_2 excitation reacts with
385 adsorbed H_2O to produce $\cdot\text{OH}$ (Eq. (9)), which gradually oxidizes NH_4^+ to NO_3^- (Eq.
386 (10)). In our previous study, we demonstrated that irradiated $(\text{NH}_4)_2\text{SO}_4\text{-TiO}_2$ samples
387 had lower NH_4^+ and NO_3^- peaks (Shang et al., 2017). Therefore, more NO_3^-
388 participated in the photocatalytic renoxification process via the
389 $\text{NO}_3^- \text{-NO}_3 \cdot \text{-HCHO-HNO}_3\text{-NO}_x$ pathway to generate NO_x . Moreover, the results
390 without HCHO are shown in Figure [4aS12](#), both $\text{NH}_4\text{NO}_3\text{-TiO}_2$ particles and
391 $\text{KNO}_3\text{-TiO}_2$ particles produced almost no NO_x , indicating the importance of HCHO

392 for renoxification to occur. Due to the high content of NH_4NO_3 in atmospheric
 393 particulate matter, the positive effect of HCHO on the photocatalytic renoxification
 394 process may have some impact on the concentrations of NO_x and other atmospheric
 395 oxidants.

400 **Figure 3.** Effect of formaldehyde on the renoxification processes of 4 wt.%

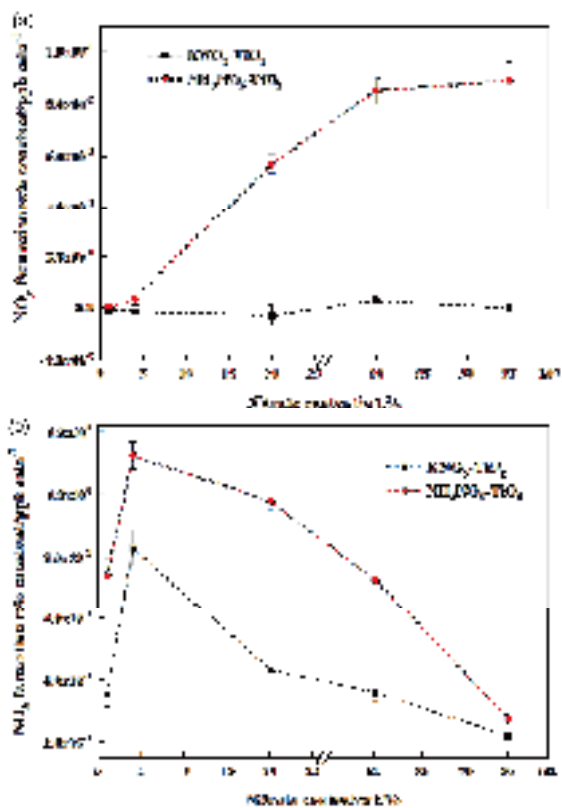

401 $\text{NH}_4\text{NO}_3\text{-TiO}_2$ and 4 wt.% $\text{KNO}_3\text{-TiO}_2$ particles at 293 K and 0.8% of relative
402 humidity. 365 nm LED lamps were used during the irradiation experiment. The initial
403 concentration of HCHO was about 9 ppm.

404

405 ~~3.3.2 The influence of nitrate content~~

406 ~~Atmospheric particles have a wide range of nitrate content; differences in the relative~~
407 ~~amounts of nitrate and TiO_2 in atmospheric particles may affect the renoxification~~
408 ~~process. Therefore, we investigated the effects of nitrate concentration gradients on~~
409 ~~renoxification. Changes in the NO_x concentrations of NO_3^- - TiO_2 composite particles,~~
410 ~~with or without HCHO, according to reaction time under 365 nm LED illumination~~
411 ~~confirmed zero order reaction kinetics. Therefore, we applied zero order rate~~
412 ~~constants to compare particles with different nitrate contents. For $\text{KNO}_3\text{-TiO}_2$, NO_x~~
413 ~~was not generated in the absence of HCHO, even at high NO_3^- nitrate concentrations~~
414 ~~(Figure 4a) because no photolysis of either NO_3^- or the NO_3 radical occurred under~~
415 ~~365 nm LED illumination. For $\text{NH}_4\text{NO}_3\text{-TiO}_2$, the rate of NO_x generation increased in~~
416 ~~the absence of HCHO as NH_4NO_3 content increased, and at higher levels (80 and 95~~
417 ~~wt.%), the NO_x generation rate constant reached a plateau at $8.0 \times 10^{-2} \text{ ppb min}^{-1}$~~
418 ~~because both NH_4^+ and NO are photochemically oxidized on TiO_2 to generate NO_3^- ,~~
419 ~~and part of this NO was oxidized to NO_2 by O_2 .(Ma et al., 2021) Higher NO_3^- content~~
420 ~~leads to higher NH_4^+ concentration; thus, more NH_4^+ participated in the generation of~~
421 ~~NO_x through photooxidation. When NO_3^- content reached 80 wt.% or higher, limited~~
422 ~~TiO_2 content in the chamber led to the saturation of NH_4^+ photooxidation, preventing~~

423 further NO_x generation. NO_x release rates over NO_3^- - TiO_2 as nitrate content increased
424 in the presence of HCHO are shown in Figure 4b. The NO_x production rate first
425 increased and then decreased, with a maximum of 4 wt.% nitrate content among both
426 KNO_3 - TiO_2 and NH_4NO_3 - TiO_2 particles. This increasing trend was caused by the
427 increased opportunities for contact between TiO_2 and NO_3^- as nitrate content
428 increased, which facilitated the combination of h^+ with NO_3^- to form NO_3^{\cdot} . The trend
429 began to decrease when nitrate content exceeded 4 wt.%. Higher NO_3^- content
430 hindered reactions on the surface of TiO_2 , but rapidly decreased the Brunauer, Emmett
431 and Teller (BET) surface area of the composite particles (Shang et al., 2017), which
432 weakened HCHO uptake and particle surface reactions. The amount of NO_x produced
433 by NH_4NO_3 - TiO_2 was consistently higher than that of KNO_3 - TiO_2 . The possible
434 reasons for this difference are as follows. First, like the K^+ blocking effect discussed
435 in section 3.1, NO_3^{\cdot} generated from the reaction of NO_3^- with h^+ was weakened; thus,
436 little adsorbed HNO_3 was available for further renoxification. Additionally, NH_4^+ can
437 undergo a photooxidation reaction to generate more NO_x by TiO_2 , as occurs in the
438 absence of HCHO.

439
 440 **Figure 4.** Effect of nitrate content (1 wt.%, 4 wt.%, 20 wt.%, 80 wt.% and 95 wt.%)
 441 on the release of NO₃⁻ for NH₄NO₃-TiO₂ and KNO₃-TiO₂ at 293 K and 0.8% of
 442 relative humidity. 365 nm LED lamps were used during the illumination experiment.
 443 (a) without HCHO; (b) the initial concentration of HCHO was about 9 ppm.

444 **3.3.23 The influence of relative humidity**

445 Water on particle surfaces can participate directly in the heterogeneous reaction
 446 process. As shown in Eq. (9), H₂O ~~is can be~~ captured by h⁺ to generate ·OH with
 447 strong oxidizability in photocatalytic reactions. The first-order photolysis rate
 448 constant of NO₃⁻ on TiO₂ particles decreases by an order of magnitude, from (5.7 ±

Formatted: Indent: First line: 2 ch

449 $0.1) \times 10^{-4} \text{ s}^{-1}$ on dry surfaces to $(7.1 \pm 0.8) \times 10^{-5} \text{ s}^{-1}$ when nitrate is coadsorbed
450 with water above monolayer coverage (Ostaszewski et al., 2018). We explored the
451 positive effect of HCHO on the NO_3^- - TiO_2 particle photocatalytic renoxification at
452 different RH levels; the results are shown in Figure 54a. For KNO_3 - TiO_2 particles, the
453 rate of NO_x production decreased as the RH of the environmental chamber increased,
454 indicating that increased water content in the gas phase hindered photocatalytic
455 renoxification for two reasons: H_2O competes with NO_3^- for h^+ on the surface of
456 TiO_2 to generate $\cdot\text{OH}$, reducing the generation of $\text{NO}_3\cdot$, and competitive adsorption
457 between H_2O and HCHO causes the generated $\cdot\text{OH}$ to compete with $\text{NO}_3\cdot$ for HCHO,
458 hindering the formation of $\text{HNO}_3(\text{ads})$ on particle surfaces. Moreover, it is also
459 possible that the loss of NO_x on the wall increases under high humidity conditions,
460 resulting in a decrease in its concentration. This competitive process also occurs on
461 the surface of NH_4NO_3 - TiO_2 particles, but at $\text{RH} = 70\%$, the NO_x generation rate
462 constant is slightly higher. The deliquescent humidity of NH_4NO_3 at 298 K is $\sim 62\%$,
463 such that NH_4NO_3 had already deliquesced at $\text{RH} = 70\%$, forming an
464 $\text{NH}_4^+/\text{NH}_3$ - NO_3^- liquid system on the particle surfaces. This quasi-liquid phase
465 improved the dispersion of TiO_2 in NH_4NO_3 , resulting in greater NO_x release. The
466 deliquescent humidity of KNO_3 - TiO_2 was $> 90\%$, (2009) such that no phase change
467 occurred at $\text{RH} = 70\%$, and the renoxification reaction rate retained a downward trend.
468 In the presence of H_2O , in addition to the NO_3^- - $\text{NO}_3\cdot$ -HCHO- HNO_3 pathway
469 observed in this study, there are a variety of HNO_3 generation paths, such as the
470 hydrolysis of N_2O_5 via the NO_2 - N_2O_5 - HNO_3 pathway (Brown et al., 2005), the

471 oxidation of NO₂ by ·OH (Burkholder et al., 1993), and the reaction of NO₃· with
472 H₂O (Schutze and Herrmann, 2005), all of which require further consideration and
473 study.

474 The formation rates of NO and NO₂ are shown in Figure 54b and c, respectively.
475 NO₂ was the main product of surface HNO₃ photolysis. Under humid conditions,
476 generated NO₂(ads) continued to react with H₂O adsorbed on the surface to form
477 HONO(ads). HONO was desorbed from the surface and released into the gas phase
478 (Zhou et al., 2003; Bao et al., 2018; Pandit et al., 2021), providing gaseous HONO to
479 the reaction system. Because the NO_x concentration remained high, the effect of
480 HONO on NO_x analyzer results was negligible (Shi et al., 2021). As NO₂ can form
481 NO₂⁻ with e⁻, a reverse reaction also occurred between NO₂⁻ and HONO in the
482 presence of H₂O (Ma et al., 2021; Garcia et al., 2021). Therefore, the increase in H₂O
483 increased the proportion of HONO in the nitrogen-containing products, such that the
484 NO_x generation rate decreased as RH increased. Comparing Figure 54b and c shows
485 that, as RH increased, the NO production rate constant decreased more than that of
486 NO₂. HONO and NO₂ generated by the photolysis of HNO₃(ads) decreased
487 accordingly, i.e., the NO source decreased. However, generated NO₂ and NO
488 underwent photocatalytic oxidation on the surface of TiO₂, and NO photodegradation
489 was more significant under the same conditions (Hot et al., 2017). Generally, a certain
490 amount of HONO will be generated during the reaction between HCHO and
491 NO₃⁻-TiO₂ particles when RH is high, which affects the concentrations of
492 atmospheric ·OH, NO_x, and O₃. This process is more likely to occur in summer due to

493 high RH and light intensity affecting atmospheric oxidation. In drier winters or dusty
 494 weather, when TiO₂ content is high, HCHO greatly promotes the photocatalytic
 495 renoxification of NO₃⁻-TiO₂ particles, thereby releasing more NO_x into the
 496 atmosphere, affecting the global atmospheric nitrogen budget. Thus, regardless of the
 497 seasonal and regional changes, renoxification has significant practical importance.

498

499
 500 **Figure 54.** Effect of relative humidity on the release of NO_x (a), NO₂ (b), NO (c) over
 501 4 wt.% NH₄NO₃-TiO₂ and 4 wt.% KNO₃-TiO₂ particles at 293 K. 365 nm LED lamps
 502 were used during the illumination experiment. The initial concentration of HCHO was
 503 about 9 ppm.

504 3.3.43 The influence of initial HCHO concentration

505 To explore whether HCHO promotes nitrate renoxification at natural
 506 concentration levels, we reduced the initial concentration of HCHO in the
 507 environmental chamber by a factor of 10, to ~1.0 ppm. The positive effect of HCHO
 508 on the photocatalytic renoxification of KNO₃-TiO₂ particles was clearly weakened,
 509 with NO₂ concentration first increasing and then decreasing, and NO concentration
 510 remaining stable (Figure S103). The HCHO concentration decreased due to its
 511 consumption during the reaction, making its positive effect decline quickly. The

512 photocatalytic oxidation reaction between NO_x and photogenerated reactive oxygen
513 species (ROS) on the TiO_2 surface further decreased the NO_x concentration.
514 Photocatalytic oxidation of NO_x by ROS on TiO_2 particles occurred at an HCHO
515 concentration of 9 ppm, but the positive effect of HCHO remained dominant. Thus,
516 no decrease in NO_x concentration was observed within 120 min in our experiments.

517 The concentration of HCHO in the atmosphere is relatively low, with a balance
518 between the photocatalytic oxidation decay of NO_x and the release of NO_x via
519 photocatalytic renoxification. The mutual transformation between particulate NO_3^-
520 and gaseous NO_x is more complex. The effect of low-concentration HCHO on the
521 renoxification of NO_3^- - TiO_2 particles requires further investigation. However, many
522 types of organics provide hydrogen atoms in the atmosphere, including alkanes (e.g.,
523 methane and n-hexane), aldehydes (e.g., acetaldehyde), alcohols (e.g., methanol and
524 ethanol), and aromatic compounds (e.g., phenol) that react with NO_3^\cdot to produce nitric
525 acid (Atkinson, 1991). These organics, together with HCHO, play similar positive
526 roles in photocatalytic renoxification and, therefore, influence NO_x concentrations.

527

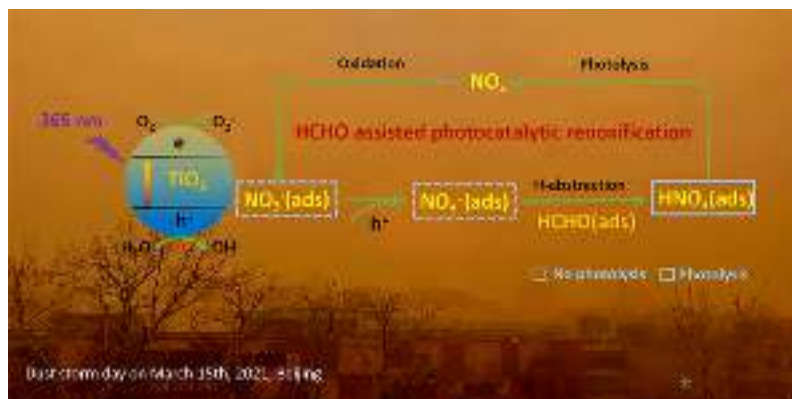

528

529 **4 Atmospheric implications**

530 Nitric acid and nitrate are not only the final sink of NO_x in the atmosphere but
531 are also among its important sources. NO_x from nitrate through renoxification is easily
532 overlooked. The renoxification of nitrate on the surface of TiO_2 particles can be
533 divided into photolytic renoxification and photocatalytic renoxification. The

534 photocatalytic performance of TiO₂ promotes the renoxification process, which
535 explains the influence of semiconducting metal oxide components on atmospheric
536 mineral particles during the renoxification of nitrate. Although most previous studies
537 have focused on solid-phase nitrate renoxification, our exploration of the roles of
538 HCHO in this study will allow us to examine complex real-world pollution scenarios,
539 in which multiple atmospheric pollutants coexist, as well as the effects of organic
540 pollutants on the renoxification process. Atmospheric HCHO is taken up at the
541 surface of particulate matter, accounting for up to ~50% of its absorption (Li et al.,
542 2014), such that the heterogeneous participation of HCHO during renoxification is
543 important. This study is the first to report that HCHO has a positive effect on the
544 photocatalytic renoxification of nitrate on TiO₂ particles, via the
545 NO₃⁻-NO₃·-HCHO-HNO₃-NO_x pathway (Figure 65), further increasing the release of
546 NO_x and other nitrogen-containing active species, which in turn affects the
547 photochemical cycle of HO_x radicals in the atmosphere and the formation of
548 important atmospheric oxidants such as O₃. Although in the case of high
549 concentrations of HCHO in our experiment, the response to the real situation will be
550 biased, the results of this study illustrate a possible way of HCHO in influencing
551 nitrate renoxification in the atmosphere. Factors such as particulate matter
552 composition, RH, and initial HCHO concentration all influence the positive effect of
553 HCHO; notably, H₂O competes with NO₃⁻ for photogenerated holes. Based on these
554 findings, two balance systems should be explored in depth: the influence of RH on the
555 generation rates of HONO and NO_x, as water increases the proportion of HONO in

556 nitrogen-containing products; and the balance between the photocatalytic degradation
 557 of generated NO_x on TiO_2 particles and the positive effect of HCHO on NO_x
 558 generation at low HCHO concentrations.

559
 560 **Figure 65.** Positive role of HCHO on the photocatalytic renoxification of nitrate- TiO_2
 561 composite particles via the NO_3^- - NO_3^\cdot -HCHO- HNO_3 - NO_x pathway.

562 Based on our results, we conclude that in photochemical processes on the
 563 surfaces of particles containing semiconductor oxides, with the participation of
 564 hydrogen donor organics, a significant synergistic photocatalytic renoxification
 565 enhancement effect alters the composition of surface nitrogenous species via the
 566 NO_3^- - NO_3^\cdot -hydrogen donor- HNO_3 - NO_x pathway, thereby affecting atmospheric
 567 oxidation and nitrogen cycling. The positive effect of HCHO can be extended from
 568 TiO_2 in this study to other components of mineral dust such as Fe_2O_3 and ZnO with
 569 photocatalytic activity, which may have practical applications. Our proposed reaction
 570 mechanism by which HCHO promotes photocatalytic renoxification will improve
 571 existing atmospheric chemistry models and reduce discrepancies between model
 572 simulations and field observations.
