21 **Abstract.** Recently, volatile chemical products (VCPs) have been increasingly recognized as important precursors for  
22 secondary organic aerosol (SOA) and ozone in urban areas. However, their atmospheric chemistry, physical  
23 transformation, and their impact on climate, environment, and human health remain poorly understood. Here, the yields  
24 and chemical composition at the molecular level of gas and particle phase products originating from the photooxidation  
25 of one of these VCPs, benzyl alcohol (BnOH), are reported. The SOA was generated in the presence of seed aerosol from  
26 nebulized ammonium sulfate solution in a 14.5 m<sup>3</sup> smog chamber operated in flow mode. More than 50 organic  
27 compounds containing nitrogen and/or up to seven oxygen atoms were identified by mass spectrometry. While a detailed  
28 non-targeted analysis has been made, our primary focus has been to examine highly oxygenated and nitro-aromatic  
29 compounds. The major components include ring-opening products with high oxygen to carbon ratio (e.g., malic acid,  
30 tartaric acids, arabic acid, trihydroxy-oxo-pentanoic acids, and pentaric acid), and ring-retaining products (e.g.,  
31 benzaldehyde, benzoic acid, catechol, 3-nitrobenzyl alcohol, 4-nitrocatechol, 2-hydroxy-5-nitrobenzyl alcohol, 2-  
32 nitrophenol, 3,4-dihydroxy-5-nitrobenzyl alcohol). The presence of some of these products in the gas and particle  
33 phases simultaneously provides evidence of their gas/particle partitioning. These oxygenated oxidation products made  
34 dominant contributions to the SOA particle composition in both low and high NO<sub>x</sub> systems. Yields, organic mass to  
35 organic carbon ratio, and proposed reaction schemes for selected compounds are provided. The aerosol yield was 5.2%  
36 for BnOH/H<sub>2</sub>O<sub>2</sub> at SOA concentration of 52.9 μg m<sup>-3</sup> and ranged between 1.7-8.1 % for BnOH/NO<sub>x</sub> at SOA concentration  
37 of 40.0-119.5 μg m<sup>-3</sup>.

compounds, SOA

## 49 **1 Introduction**

50 Modeling atmospheric organic aerosol (OA) using chemical transport models (CTMs) is complex, challenging, and  
51 often can lead to model-measurement discrepancies (Zhao et al., 2016). Applying CTMs to urban areas reveals that  
52 traditional VOCs including combustion-related processes cannot account for the observed OA mass, leaving a substantial  
53 fraction unresolved (Hayes et al., 2015). Recent studies suggest that this discrepancy is due in part to unaccounted, rapidly  
54 reacting SOA and ozone precursors from unknown sources (Hodzic et al., 2009; Hayes et al., 2015; McDonald et al., 2018;  
55 Akherati et al. 2019; Lu et al., 2020). Volatile chemical products (VCPs), such as personal care products, cleaning agents,  
56 coatings, adhesives, and pesticides have emerged as possible sources in urban areas (McDonald et al., 2018). Their  
57 emissions can be larger than those from usual sources, such as motor vehicles (Coggon et al., 2021). Laboratory, modeling,  
58 and field studies for VCPs have been conducted to assess their potential to affect ambient OA and ozone formation in  
59 urban and suburban locations (McDonald et al., 2018; Khare et al., 2018; Stockwell et al., 2021; Seltzer et al., 2021;  
60 Gkatzelis et al., 2021; Milani et al., 2021; Pennington et al., 2021; Coggon et al., 2021). The contribution of VCPs to  
61 ambient OA is not fully understood and only limited modeling studies have been reported (Mohr et al., 2015; Vlachou et  
62 al., 2018; Pennington et al., 2021; Qin et al., 2021; Seltzer et al., 2021). Additionally, few experimental and chamber  
63 studies of VCPs have been conducted with limited characterization of aerosol products (Wu and Johnston, 2016, 2017;  
64 Harrison and Well, 2012; Charan et al., 2020, 2021; Humes et al., 2022). For example, the analysis of SOA from the  
65 oxidation of cyclic methyl siloxanes (Wu and Johnston, 2016, 2017; Fu et al. 2020; Alton and Browne, 2020; Charan et  
66 al., 2021) and cyclic siloxanes (Janecek et al., 2019) has been conducted. Kinetic studies with limited products  
67 characterization have been reported for the oxidation of benzyl alcohol (BnOH) by hydroxyl radicals (Bernard et al.,  
68 2013; Wang, 2015; Harrison and Well, 2009, 2012). Recently, Humes et al. (2022) highlight the importance of oxygenated  
69 aromatic VCPs emission to generate urban SOA and oxygenated products in both gas and aerosol phases. Therefore,  
70 understanding the atmospheric chemistry of VCPs is important to assess their role in air quality and climate and to improve  
71 SOA chemistry in CTMs thereby allowing for better estimates in health studies and source apportionment.

72 The challenges associated with evaluating VCP impacts on urban OA can be addressed by identifying atmospheric  
73 VCP concentrations and SOA markers linking those VCP to ambient particulate matter (PM). Benzyl alcohol ( $C_7H_8O$ ) is  
74 an important ring containing VCP used as an organic intermediate and a solvent in a wide range of applications (Antonelli  
75 et al. 2002). BnOH is emitted also from flowers and flowering trees (Do et al., 1969; Horvat et al., 1990; Larsen and Poll,  
76 1990; Humpf and Scheier, 1991; Boatright et al., 2004; Vallat and Dorn, 2005; Orlova et al.; 2006) and found in indoor

77 air (Weschler, 2011). Gas kinetic studies of loss rates and product distributions have been conducted using flow tubes and  
78 environmental chambers. Bernard et al. (2013) examined the rate and mechanisms of the OH + BnOH reaction. Similarly,  
79 Harrison and Wells (2009, 2012) investigated the rate constants for the BnOH reaction with ozone, OH and NO<sub>3</sub> radicals.  
80 Carter et al. (2005) conducted chamber experiments to assess ozone and PM formation from BnOH and related  
81 compounds. Product studies from BnOH oxidation have focused mainly on gas phase (GP) products. Several carbonyl  
82 products (benzaldehyde (BnAld), formaldehyde, glyoxal, butenedial, 4-oxopentanal, 3-hydroxy-2-propanaldehyde), and  
83 benzyl nitrate, o-hydroxybenzyl alcohol, o-dihydroxy benzene were reported from the above studies. With respect to the  
84 particle phase (PP), Charan et al. (2020) reported aerosol yields from BnOH oxidation together with a limited number of  
85 SOA products. Finally, Wang (2015) conducted a theoretical study to elucidate the reaction mechanism of the oxidation  
86 of BnOH with OH radicals.

87 In this study, we report a detailed non-targeted chemical analysis of GP and SOA products originated from the  
88 photooxidation of BnOH in the presence and absence of oxides of nitrogen (NO<sub>x</sub>), with the aim to better understand the  
89 chemical composition at the molecular level. Gas chromatography-mass spectrometry (GC-MS) and high-performance  
90 liquid chromatography were used for the identification of a range of organic compounds including oxygenated  
91 nitroaromatics and related compounds bearing up to seven oxygen atoms. Nitroaromatics are pollutants of concern due to  
92 their toxicity, light-absorption properties, and relatively long residence times in the environment. Highly oxygenated  
93 compounds can partition into pre-existing particles or be involved in new particle formation. Also, in the present study,  
94 SOA and secondary organic carbon (SOC) yields were measured with the results compared to published data. A chemical  
95 mechanism is then proposed to represent and account for selected gas- and aerosol-phase products observed in this study.

96

## 97 **2 Experimental methods**

98 All chemicals including N, O-*bis*(trimethylsilyl) trifluoroacetamide (BSTFA) derivatization reagent with 1%  
99 trimethylchlorosilane (TMCS) as catalyst and benzyl alcohol (99%), 2-methyl-4-nitrophenol, L-(+)-tartaric acid, D-(-)-  
100 tartaric acid, and meso-tartaric acid were purchased from Aldrich Chemical Co. (Milwaukee, WI) at the highest purity  
101 (99.8%) available and were used without further purification. In addition to standards reported in our previous studies  
102 (Jaoui et al., 2004; 2018), 3-nitrobenzyl alcohol, benzoic acid, and 4-nitrocatechol were purchased from Tokyo Chemical  
103 Industry (OR, USA); while pentaric acid, 2,3-dihydroxy-4-methoxy-4-oxobutanoic acid, and arabic acid were obtained  
104 from Aurum Pharmatech, LLC (NJ, USA).

## 105 **2.1 Chamber description and operation**

106 All experiments were conducted in a 14.5 m<sup>3</sup> fixed-volume chamber having TFE Teflon coated walls and maintained  
107 at a positive pressure of 0.1 Torr. The chamber operation, procedures, and instrumentation have been described previously  
108 (Kleindienst et al. 2006; 2009), and here just experiment-specific details are primarily included. A combination of  
109 fluorescent bulbs having radiation from 300-400 nm was used to photolyze NO<sub>2</sub>. In the absence of NO<sub>x</sub>, the radiation  
110 system was altered to include UV-313 sunlamps to adequately photolyze H<sub>2</sub>O<sub>2</sub>. The chamber was operated in steady-state  
111 (SS or flow) mode to provide continuously stable effluent concentrations. Under these conditions, reactants and products  
112 equilibrate with the chamber surfaces to minimize irreversible losses of gases and particles. The SS operation allows for  
113 extended sampling periods to improve the accuracy and precision of the measurements (Shilling et al., 2008).  
114 Temperature, relative humidity, and UV light intensity were measured continuously with an uncertainty of 5%. Pre-  
115 experiment and post-experiment procedures (see section 2.5 below) were routinely carried out before and after each  
116 experiment to minimize contamination in the chamber. The reactant generation system provided constant sources of zero  
117 air, reactants, water vapor, and ammonium sulfate (AS) seed aerosol. The reactant flow of gases (e.g., NO<sub>x</sub>) into the  
118 chamber was regulated using mass flow controllers. BnOH was injected using a syringe pump, vaporized in a heated glass  
119 bulb, and injected with zero air. For experiments in the absence of NO<sub>x</sub>, a 50% aqueous solution of H<sub>2</sub>O<sub>2</sub> was vaporized  
120 and injected using a second syringe pump, and photolyzed to produce OH radicals. Typical chamber AS concentrations  
121 were approximately 1 µg m<sup>-3</sup>. Each SS experiment went through an initial transient period of 18-24 h until the reactant  
122 and product concentrations reached steady state.

123

## 124 **2.2 Gas-phase measurements**

125 A wide variety of instruments were used to measure the reactants and products. Nitric oxide (NO) and NO<sub>x</sub> were  
126 measured with a TECO (Franklin, MA) oxides of nitrogen analyzer with an upstream nylon filter to remove nitric acid  
127 produced from OH + NO<sub>2</sub>. The NO<sub>x</sub> analyzer was calibrated with a NIST-traceable NO standard. Initial H<sub>2</sub>O<sub>2</sub>  
128 concentrations were estimated by UV absorption using the ratio of the H<sub>2</sub>O<sub>2</sub> to O<sub>3</sub> absorbances at 254 nm, as described  
129 by Kleindienst et al. (2009). Experiments in the absence of NO<sub>x</sub> were conducted dry to avoid aqueous loss of H<sub>2</sub>O<sub>2</sub>. BnOH  
130 concentrations in the inlet and within the chamber were measured semi-continuously using an SRI Model 8610C compact  
131 gas chromatograph with flame ionization detector (GC-FID; SRI Instruments, Torrance CA). The purity of the BnOH  
132 was verified with GC-MS analysis.

133 Low molecular weight carbonyls and dicarbonyls were quantified by derivatization using 2,4-dinitrophenylhydrazine  
134 (Smith et al., 1989). Samples were collected at 0.5 L min<sup>-1</sup> for 25 min and derivatized in a 4 mL solution of acidified  
135 DNPH and then heated for 40 min at 70°C. Air samples were drawn for 20 min at a rate of 0.50 L min<sup>-1</sup> through an  
136 impinger containing 5 mL of a DNPH solution in acetonitrile. The resulting solutions were analyzed by high-performance  
137 liquid chromatography with a ultraviolet detector (HPLC/UV) (Smith et al., 1989). A 15-component hydrazone standard  
138 (comprising formaldehyde-, acetaldehyde-, acrolein, acetone-, propionaldehyde-, crotonaldehyde-, methacrolein-,  
139 butyraldehyde-, 2-butanone-, BnAld-, glyoxal-, valeraldehyde-, m-tolualdehyde-, methylglyoxal-, and hexaldehyde;  
140 AccuStandard, Inc.) at a free carbonyl concentration of 30 µg mL<sup>-1</sup> for each component was used for calibration. Separate  
141 dihydrazone standards of glyoxal-DNPH and methylglyoxal-DNPH were also formulated. Carbonyls were separated  
142 using a Hewlett-Packard (HP) 1100 HPLC system having an Agilent Zorbax ODS 4.6 x 250 mm, 5-µm column maintained  
143 at 30°C eluted with binary acetonitrile-water gradient. A 10 µL injection volume was used for all standards and samples.  
144 Carbonyls were quantified by UV absorption with a diode array detector set to 360 nm. Control and sample processing  
145 were managed with HP ChemStation software. More highly oxidized gas-phase organic species were also collected with  
146 a 60-cm, 4-channel XAD4-coated annular denuder for off-line analysis (Jaoui and Kamens, 2001). Once collected, the  
147 denuders were extracted and analyzed according to the methodology described in section 2.4 below.

148

### 149 **2.3 Aerosol-phase: bulk parameter measurements**

150 Organic carbon (OC) was measured using a semi-continuous elemental carbon-organic carbon (EC-OC) instrument  
151 (Sunset Laboratories, Tigard, OR) (Offenberg et al., 2007). The pumping system draws chamber effluent through a quartz  
152 filter at a rate of 8 L min<sup>-1</sup> with carbon-strip denuder to remove gas-phase organics that might interfere with the  
153 measurement. With a sample collection time of 0.5 h and an analysis time of 0.25 h, the duty cycle for the measurement  
154 of OC was 0.75 h (Lewandowski et al., 2015). The aerosol volume, size distribution, and total number density were  
155 measured using a scanning mobility particle sizer (SMPS), (Model 3071A, TSI, Inc., Shoreview, MN) and a condensation  
156 particle counter (CPC) (Model 3010, TSI, Inc., Shoreview, MN). The SMPS operating conditions were as follows: sample  
157 flow 0.2 L min<sup>-1</sup>; sheath flow 2 L min<sup>-1</sup>; size scan from 19 to 982 nm.

158

### 159 **2.4 Molecular characterization of GP and PP oxygenated organic products**

160 A non-targeted chemical analysis was conducted focusing mainly on species bearing hydroxy and carboxylic groups  
161 (Jaoui et al., 2004, 2013, 2018). For each experiment, six 47-mm glass fiber (GF) filters were taken for 24 h at a flow rate  
162 of 16.7 L min<sup>-1</sup>. A second set of samples used an in-line 60-cm XAD-4 coated annular denuder (followed by a GF filter)  
163 and analyzed for gas-phase organic products (Jaoui and Kamens, 2001). After collection, GF filters were extracted by  
164 sonication with 5 mL methanol for 1 h, and denuders were extracted with 30 mL 1:1 dichloromethane/methanol mixture  
165 (Jaoui and Kamens, 2001). Prior to extraction, denuders and GF filters were spiked with *cis*-ketopinic acid (KPA), trans-  
166 p-menth-6-ene-2,8-diol (PMD), and d<sub>50</sub>-tetracosane (TCS) as internal/recovery standards (IS/RS). Denuder extraction  
167 solvents were rotary evaporated to ~1 mL and filtered using 0.45- $\mu$ m PTFE syringe filters. A 2  $\mu$ L portion of this extract  
168 was analyzed by GC-MS (Jaoui and Kamens, 2001). The remaining denuder and filter extracts were evaporated to dryness  
169 under a gentle stream of N<sub>2</sub> at room temperature using an N-Evap evaporation bath (Organomation Associates, Inc.,  
170 Berlin, MA), then derivatized with BSTFA (Jaoui et al., 2004). This technique provides a sensitive method for measuring  
171 low levels of highly oxidized organic compounds, including semi- and intermediate-volatile compounds in the GP and  
172 PP.

173 The GC-MS analysis was conducted on an Agilent GC (7890B) coupled with a quadrupole mass spectrometer  
174 (5977B). The injector, heated to 270 °C, was operated in splitless mode. Compounds were separated on a 60-m-long, 0.25-  
175 mm-i.d. RTx-5MS column (Restek, Inc., Bellefonte, PA) with a 0.25- $\mu$ m film thickness. The GC oven temperature was  
176 initiated at 84 °C, held for 1 min, then increased at 8 °C min<sup>-1</sup> to 200 °C, followed by a 2-min hold, then an increase at 10  
177 °C min<sup>-1</sup> to 300 °C and a 15-min hold. The ion source, ion trap, and interface temperatures were 200, 200, and 300 °C,  
178 respectively. Mass spectra were collected in both the methane-chemical (CI) and electron ionization (EI) modes.

179

## 180 **2.5 Experimental and quality control procedures**

181 Before each experiment started, the chamber was flushed with zero air (hydrocarbon-free) for 24 h from an Aadco  
182 clean generator (Cleves, OH, USA). Experiments were conducted in either the absence or presence of NO<sub>x</sub>. For  
183 experiments with NO<sub>x</sub>, BnOH and NO were added to the chamber through flow controllers to the target concentration.  
184 For experiments in the absence of NO<sub>x</sub>, the photolysis of H<sub>2</sub>O<sub>2</sub> was the source of OH. H<sub>2</sub>O<sub>2</sub> as a 50 % aqueous solution  
185 was injected through a syringe pump into a heated glass bulb where it vaporized and then was mixed rapidly by the main  
186 dilution air flow. For these experiments, BnOH was added as described above. Ammonium sulfate seed aerosol was also  
187 introduced into the chamber for all experiments to serve as a condensing medium for semivolatile organic products that

188 might form. After the reactants reached steady state concentrations (24 hours), the background was characterized using  
189 all instruments to check for artifacts including background GP and PP species. Background chamber air was also  
190 characterized using off-line analysis of denuder and/or filters as described above. Previous studies show that BnAld and  
191 to a lesser extent benzoic acid, benzyl benzoate and dibenzyl ether present either as impurity, or as decomposition products  
192 upon BnOH exposure to air at room temperature or sonication (Urakami et al., 2000; Ferri et al., 2006; Abend et al., 2004).  
193 Here we investigated the effect of chamber air, sonication, and BSTFA derivatization on BnOH artifacts as described in  
194 the supplementary information (SI) in section 1. A small amount of BnAld impurity was detected using the direct injection  
195 (DI) method and estimated to be <0.1% in the purchased solution. When BnOH was exposed to clean air in the chamber  
196 in the absence of light, sonication, and/or BSTFA derivatization, our results show additional low level of BnOH  
197 conversion to BnAld and benzoic acid using DI and BSTFA methods, which is similar to the findings of Abend et al.  
198 (2004), Urakami et al. (2000), and Ferri et al. (2006). Additional results and descriptions are provided in section S1 (SI).

199 Experiments were initiated by turning on the lights and allowing the irradiated chamber effluent to reach SS  
200 conditions over a 24-h period which permits active sampling by the on-line instruments and the collection of denuder and  
201 filter samples for subsequent off-line analysis. For organic intermediates wall losses are typically not an issue due to  
202 reactions being conducted within a Teflon chamber. This potential issue is mitigated further from operating the chamber  
203 in a SS mode where compound loss and re-evaporation quickly comes to steady state. Short lifetimes of radical  
204 intermediates with other gas-phase constituents also render a negligible wall-loss. The stability of BnOH in the chamber  
205 was investigated and BnOH was found to be highly stable with results given in the SI (section S1). Denuders and GF filter  
206 samples were also analyzed to probe reproducibility of the analytical technique. The analysis showed consistent results.

207 Gas and particle samples from BnOH photooxidation are dominated by oxygenated species, several not having  
208 authentic standards, and thus a portion of each sample was derivatized. Initially, we eliminated peaks detected in blank  
209 and background samples. For compounds having standards, comparisons were made between the retention times and mass  
210 spectra (CI and/or EI mode) of the chamber-derived peaks and those of the standards. For compounds not having  
211 standards, individual peak identifications were associated with a product peak only if its retention time and mass spectrum  
212 was consistent with the fragmentation pattern of the BSTFA-derivatized compound. All recorded spectra in this study  
213 were compared with those derived from reference standards, the literature, the NIST library, and an archive of mass  
214 spectra from product compounds determined in our laboratory over the past twenty years.

215

### 216 3 Results and discussion

217 The initial conditions of the experiments conducted in this study are summarized in Table 1. Three NO<sub>x</sub> experiments  
218 were carried-out with initial BnOH ranging from 0.36 – 0.72 ppm and NO from 0.096 – 0.19 ppm. One experiment without  
219 NO<sub>x</sub> was conducted with initial H<sub>2</sub>O<sub>2</sub> and BnOH levels of 3.0 and 0.32 ppm, respectively. NO<sub>x</sub> experiments were  
220 conducted at ~30% RH, and the H<sub>2</sub>O<sub>2</sub> experiment at < 4% RH to minimize H<sub>2</sub>O<sub>2</sub> uptake onto chamber surfaces. Chamber  
221 temperatures were set to 25 °C. Each experiment was conducted for up to five days for samples requiring substantial  
222 masses or extended collection times and frequencies.

223 Steady state concentrations of NO, BnOH, O<sub>3</sub>, and NO<sub>y</sub> for the four experiments are given in Table 2. The reacted  
224 BnOH and NO were calculated from the difference between the initial and steady-state concentrations. For NO<sub>x</sub>  
225 experiments, the range of reacted BnOH concentrations was 0.22 – 0.34 ppm having a reproducibility of 20–30%. Under  
226 these conditions, steady state concentrations of NO<sub>y</sub>, and O<sub>3</sub> were in the range of 0.08 – 0.16 and 0.011 – 0.15 ppm,  
227 respectively. With NO present at steady-state, peroxy-peroxy (RO<sub>2</sub>–RO<sub>2</sub>) reactions were minimized. A constant aerosol  
228 source was maintained for initial conditions given in Table 1. The major aerosol parameters measured (SOA, SOC, and  
229 OM/OC) are given in Table 3. SOC uncertainties were taken from the reproducibility of the semi-continuous measurement  
230 and typically better than 10% for a single run. For the organic mass (OM), the uncertainties are determined from the  
231 reproducibility of side-by-side filter measurements which are typically better than 5%. An estimate of the systematic  
232 errors due to minor changes in reactant concentrations, minor variations in chamber temperature, and similar factors bring  
233 the total uncertainty to between 15-25% for these parameters (Kleindienst et al., 2009). SOA/SOC values were then  
234 determined from the corrected data and given in Table 3. For experiments in the presence of NO<sub>x</sub>, SOA/SOC values  
235 ranged from 1.7-2.0. Similarly, in the absence of NO<sub>x</sub>, the measured SOA/SOC value was 2.1.

236

#### 237 3.1 Secondary organic aerosol and secondary organic carbon yields

238 Secondary organic aerosol yield ( $Y_{SOA}$ ) and secondary organic carbon yield ( $Y_{SOC}$ ) were calculated from the  
239 following respective relationships  $Y_{SOA} = SOA/\Delta HC$  (1);  $Y_{SOC} = SOC/\Delta HC_C$  (2) where SOA is the corrected organic  
240 aerosol mass concentration originated from filter measurements (6 filters) and  $\Delta HC$  is the reacted BnOH concentration.  
241 SOC is the organic carbon concentration found in Table 3 and  $\Delta HC_C$  is the reacted BnOH carbon concentration. SOA  
242 and SOC were corrected for wall loss to the chamber which had previously been determined for organic aerosol to be  
243  $0.067 \text{ h}^{-1}$  (Kleindienst et al. 2012). The wall loss rate is based on mass and not on the size distribution of the particles.

244 Uncertainties in the yield come from the experimental uncertainties in SOA and SOC production and the reacted BnOH  
245 concentrations. The uncertainty in the reacted BnOH results from the reproducibility of the initial and steady-state values  
246 and is estimated to range from 20 - 30% given the low volatility of BnOH and challenges for introducing oxygenated  
247 species into the chamber in a consistent manner. Such challenges are also present in a batch mode experiment given the  
248 difficulty to determine BnOH time profiles given its volatility and high reactivity toward oxidants (Shilling et al., 2008;  
249 Kroll et al., 2007). Similar findings have been reported for sesquiterpenes oxidation (Jaoui et al., 2013). As a result,  
250 aerosol yields of higher accuracy are often reported to be associated with steady state as opposed to batch mode  
251 experiments (Shilling et al., 2008). Moreover, in this work we explored the possibility of BnOH being taken up by  
252 ammonium sulfate (AS) seed aerosol prior to start of the irradiation or by SOA after it is initiated. This test was conducted  
253 using GC-MS analysis of derivatized (BSTFA) and underivatized denuder and GF filter extracts collected before and after  
254 the reaction starts (SI; Section S1). Under the experimental conditions used in this study, BnOH was undetected in AS  
255 and SOA, thus limiting any participation in particle chemistry that may occur.

256 The production of aerosol, and thus the yield, were found to be highly sensitive to the precise initial conditions (Tables 1,  
257 3). Yields for the four experiments are shown in Table 3.  $Y_{SOA}$  values were determined for SOA concentrations from 39.6  
258 - 119.5  $\mu\text{g m}^{-3}$  and ranged between 3.6 and 8.1%. Similarly,  $Y_{SOC}$  was measured for SOC concentrations from 23.2 – 58.9  
259  $\mu\text{gC m}^{-3}$  and found to range between 2.7 and 5.1%. In the absence of  $\text{NO}_x$ , SOA and SOC yields were 5.2 and 3.1 %  
260 measured for SOA and SOC concentrations of 52.9  $\mu\text{g m}^{-3}$  and 24.8  $\mu\text{gC m}^{-3}$ , respectively. For the two systems at similar  
261 SOA concentrations ER890 and ER892, the SOA yield was higher for the experiment with  $\text{NO}_x$ . This may result from  
262 the reaction of BnOH with  $\text{NO}_x$  which tends to produce high levels of BnAld (Table 4), which may undergo secondary  
263 reactions leading to additional SOA formation (see section 3.3). The BnOH reaction with NO will occur when the reaction  
264 of  $\text{RO}_2$  with NO is competitive to ring closure. Regardless, according to Wang (2015) the reaction of  $\text{NO}_2$  with R1  
265 (Scheme 1) will occur only to a minor degree compared with ring closure. As expected, the data in Table 3 indicate that  
266  $Y_{SOA}$  and  $Y_{SOC}$  are lower at the lower SOA and SOC concentrations, respectively.

267 These SOA and SOC yields can be compared with other studies. Recently, Charan et al. (2020) reported SOA yields  
268 for the photooxidation of BnOH in the presence of  $\text{NO}_x$  with the initial OH coming from the photolysis of  $\text{H}_2\text{O}_2$ . Their  
269 chamber was operated in a batch mode and SOA yields approaching unity were reported. By contrast, three additional  
270 studies reported much lower SOA yields of 9%, 30%, and 41% from McDonald et al. (2018), Carter et al. (2005), and Li  
271 et al. (2018), respectively. The yield reported by McDonald et al. (2018) was based on a multi-generation oxidation model;

272 that of Carter et al. (2005) was estimated as described in the original report, and that of Li et al. (2018) was based on  
273 measurements in the presence of NO<sub>x</sub> and a surrogate urban hydrocarbon. The results of our study are much closer in  
274 value to McDonald et al. (2018). The study by Charan et al. (2020) suggests that conditions can be found where BnOH  
275 SOA yields are substantially greater than that found in this study and those previously reported. The major differences  
276 between the Charan et al. study and the present work were the chamber-mode operation, the seed aerosol type and levels,  
277 and the mix of oxidants used. While it can be difficult to compare the yields from the two studies some comments can be  
278 made. (1) As noted, the Charan et al. yields result from conventional batch mode irradiations of BnOH, H<sub>2</sub>O<sub>2</sub> and NO<sub>x</sub>.  
279 (2) SOA levels were measured using an SMPS which measures aerosol volume which is then converted to aerosol mass  
280 using a density of 1.4 μg nL<sup>-1</sup>. (3) Perhaps the biggest difference between the two studies is the use of an extremely high  
281 initial seed aerosol mass, approximately two orders of magnitude higher than in this study. Thus, it is possible that an  
282 adsorption mechanism played a part in contributing to the measured yields. (4) Finally, the use of high initial H<sub>2</sub>O<sub>2</sub>  
283 concentrations relative to BnOH make it possible that H<sub>2</sub>O<sub>2</sub> effectively competed with BnOH for OH via the reaction of  
284 OH + H<sub>2</sub>O<sub>2</sub> → HO<sub>2</sub> + H<sub>2</sub>O thus generating a system rich in HO<sub>2</sub>. Thus, aging process may be more prominent than in our  
285 study. The uncertainties associated with SOA and reacted BnOH measurements and wall loss correction are unlikely to  
286 account for the differences in the two studies. However, SOA yields have been reported to increase considerably as a  
287 function of initial seed aerosol (Zhang et al. 2014), as well as to increase with the OH radical exposure (Wang et al.,  
288 2018). Qualitatively these two factors might bring the present SOA yields into reasonable agreement with Charan et al.  
289 (2020), when data were extrapolated to similar seed aerosol and OH exposures. And as previously noted, in the low initial  
290 seed aerosol used in our study no benzyl alcohol was detected in the seed aerosol or deposited on SOA. As further  
291 plausibility for the results from the present study, Humes et al. (2022) recently reported yields from 12% - 18% for two  
292 oxygenated aromatic species (1-phenoxy-2-propanol, and phenoxy-ethanol), compounds having similar structures to  
293 BnOH.

294

### 295 **3.2 Reaction products identification**

296 Three methods were used in this study to identify oxygenated reaction products at the molecular level: (1) DNPH as  
297 derivatizing agent for small carbonyls (Smith et al. 1989); (2) BSTFA as derivatizing agent for hydroxyl and carboxylic  
298 compounds for GP and PP (Jaoui et al., 2004); and (3) direct injection (DI) method providing the capability for analysing  
299 slightly polar to non-polar compounds without the use of derivatization (Jaoui and Kamens, 2001). For the BSTFA and

300 DI methods, the analysis of laboratory generated GP and PP products from BnOH oxidation shows a series of organic  
301 compounds containing nitro, ketone, carboxylic acid, and/or alcoholic functional groups. Many of these compounds do  
302 not have authentic standards and their identifications were based on the interpretation of the mass spectra of the derivatized  
303 and/or underivatized compound (Jaoui and Kamens 2001; Jaoui et al., 2004, 2005). The identification should be regarded  
304 as tentative except for compounds that have authentic standards. For the BSTFA method, the recognition of characteristic  
305 ions was used to guide the analysis of mass spectra of the derivatives obtained in both electron ionization (EI) and chemical  
306 ionization (CI) using methane as reagent gas. BSTFA reacts with -COOH and -OH groups to form BSTFA derivatives.  
307 Characteristic ions are  $m/z$  73, 75, 147, and 149. Adduct ions in CI from the derivatives include  $m/z$   $M^+ + 73$ ,  $M^+ + 41$ ,  
308  $M^+ + 29$ , and  $M^+ + 1$ ; fragment ions include  $m/z$   $M^+ - 15$ ,  $M^+ - 73$ ,  $M^+ - 89$ ,  $M^+ - 117$ ,  $M^+ - 105$ ,  $M^+ - 133$ , and/or  
309  $M^+ - 207$ . The approach used for the identification is as follows: peaks detected in blank and background chamber samples  
310 were eliminated first. A peak was associated with a reaction product only if its corresponding mass spectrum was  
311 consistent with the fragmentation pattern of the BSTFA derivatization reagent. All recorded spectra were compared with  
312 spectra derived from various reference compounds, authentic standard, NIST library, the PubChem website  
313 ([pubchem.ncbi.nlm.nih.gov](http://pubchem.ncbi.nlm.nih.gov)), and/or by MS assignment. While the off-line technique is an integrated technique that  
314 requires long sampling times, it does provide a sensitive method for products identification at the molecular level as well  
315 as measuring low concentrations of highly oxidized organic compounds, and semivolatile compounds in the GP. Thus,  
316 products found by this collection technique could be informative for possible precursors for the types of compounds that  
317 may form in the PP. In the following discussion, data are first presented to support tentative identifications of oxidation  
318 products in the GP and PP.

319 **Gas phase products.** GP measurements were made of major carbonyl products formed during the photooxidation of  
320 BnOH including formaldehyde, acetaldehyde, acetone, methacrolein, 2-butanone, BnAld, glyoxal, and methylglyoxal.  
321 Steady-state concentrations are given in Table 4. Under the conditions shown in Tables 1 and 2, high concentrations were  
322 observed for BnAld and glyoxal, and to a lesser extent formaldehyde in experiments with NO<sub>x</sub>, and high concentrations  
323 of formaldehyde, acetaldehyde, and to a lesser extent BnAld and glyoxal in the experiment without NO<sub>x</sub>. BnAld level  
324 was a factor of ~5 higher in NO<sub>x</sub> experiments compared to H<sub>2</sub>O<sub>2</sub> experiments, and formaldehyde a factor of ~36 lower.  
325 Glyoxal and methylglyoxal concentrations largely were similar in both NO<sub>x</sub> and H<sub>2</sub>O<sub>2</sub> experiments. The formation of

326 BnAld, glyoxal, and formaldehyde as major products (Table 4) have already been reported from the oxidation of BnOH  
327 with yields of 25 ( $\pm$  5), 20 ( $\pm$  2), and 3.0% ( $\pm$  0.2), respectively (Bernard et al., 2013; Harrison and Wells, 2012).

328 GP samples were also collected on five-channel annular denuders. Each denuder sample was extracted and analyzed  
329 directly with GC-MS without derivatization. The remaining extract was silylated, and GC-MS analyzed qualitatively.  
330 Typical total ion chromatograms (TIC) of GP products detected and identified in this study are shown in Figure 1. Figure  
331 1 shows portions of three TIC in +EI of GP samples taken from experiments ER889 at steady state (underivatized: Figure  
332 1a), ER892 (underivatized: Figure 1b), and ER889 (silylated derivatives: Figure 1c). Peaks assigned in Figure 1 were  
333 identified either by comparison with an authentic standard or by MS assignment. For clarity, only the main products are  
334 shown, although several peaks could not be structurally identified. SOA generated from BnOH photooxidation is  
335 dominated by oxygenated ring-opening products (see below). However, ring-retaining products were among the main  
336 products observed in the GP including semivolatile organic compounds (SVOCs) (Figure 1c). Chromatograms associated  
337 with the underivatized samples (Figure 1a, b) were used mainly to identify BnOH and BnAld in the system, although  
338 several additional peaks absent in the background chromatogram were observed. At steady state, BnOH was not reacted  
339 completely as it was detected in both systems only in the GP using both DI and BSTFA methods (Figure 1). BnAld was  
340 detected in both systems in the gas and particle phases, although it was not present with BSTFA method because of the  
341 absence of OH or COOH groups. Figure S3 shows EI mass spectra of BnAld identified using authentic standard, and  
342 those associated with three peaks eluting at 11.3, 12.0, and 12.8 min. Although no structural information could be  
343 associated with these three peaks, molecular weights of 152, 152, 138 Da (all derivatized and underivatized masses are  
344 Dalton (Da) but are not designated as such hereafter), were tentatively obtained.

345 Select GP products containing OH groups identified in the present study are summarized in Table 5. Table 5 contains  
346 proposed structures, molecular weights of the silylated derivatives ( $MW_{\text{BSTFA}}$ ) and underivatized compounds ( $MW$ ),  
347 formula, and the 5 most intense ions associated with BSTFA derivatives in EI mode. Table 5 shows if GP products are  
348 detected also in the PP. Figure S4 shows EI mass spectra associated with selected peaks observed in Figure 1c, including  
349 BnOH-1TMS, benzoic acid-1TMS, catechol-2TMS, and 2-hydroxybenzyl alcohol-2TMS. 2-Hydroxybenzyl alcohol-  
350 2TMS (2OHBnOH) peak eluted at 21.4 min was one of the largest peaks detected in the chromatogram in Figure 3c. The  
351 2OHBnOH-2TMS EI mass spectrum (Figure S4, bottom) shows strong characteristic fragments ions at  $m/z$  73, 179 ( $M^+$   
352 - 89), 253 ( $M^+$  - 15), 268 ( $M^+$ ), and its corresponding CI mass spectrum shows ions at  $m/z$  253 ( $M^+$  - 15), 179 ( $M^+$  - 89)

353 and weak adducts at  $M^+ + 1$ ,  $M^+ + 29$ , and  $M^+ + 41$  that are consistent with the presence of two (-OH) groups, indicating  
354 a BSTFA derivatized molecular weight of 268 Da. Bernard et al (2013) have identified 2OHBnOH and catechol in the  
355 GP of the reaction of BnOH and OH radicals. In our study, catechol was observed only in the H<sub>2</sub>O<sub>2</sub> system in the PP.  
356 Additional peaks were observed, which their mass spectra are consistent with products bearing OH and/or COOH groups,  
357 however, their structural identification could not be obtained due to lack of authentic standards and the complexity of the  
358 interpretation of their mass spectra. BnAld was reported to undergo secondary reactions (Sankar et al., 2014) and may  
359 play an important role as precursor for some oxygenated species observed in this study.

360 **Particle phase products.** One of the advantages of conducting experiments in SS mode is collecting sufficient gas and  
361 aerosol masses on denuders and filters for qualitative and quantitative offline analysis. In this study, aerosol collected on  
362 GF filters were solvent extracted, with the resulting extracts subjected to BSTFA derivatization followed by GC-MS  
363 analysis. SOA generated from both NO<sub>x</sub> and H<sub>2</sub>O<sub>2</sub> systems was dominated by oxygenated organic compounds, for which  
364 mass spectra for more than 50 species have been recorded. These species may have undergone several generations of  
365 atmospheric oxidation. Several individual large peaks have been detected in addition to a significant number of small  
366 peaks as shown in Figure 2. Figure 2 shows portions between 9 and 28 min of the TIC chromatograms of the silylated  
367 derivatives of the aerosol extracts associated with BnOH/NO<sub>x</sub> (top) and BnOH/H<sub>2</sub>O<sub>2</sub> (bottom). The portion after 28 min  
368 is discussed in the next section. The chromatograms in Figure 2 can be directly compared because the chamber air sampled  
369 and the amount of extract analyzed for each system were the same. This evaluation revealed that more than 70% of peaks  
370 eluted from each system are identical, suggesting similar chemistry is involved in BnOH reaction products formed in the  
371 presence and absence of NO<sub>x</sub>. In addition, a series of peaks dominated by fragments with odd  $m/z$  were observed only in  
372 BnOH/NO<sub>x</sub> and their mass spectra were associated with nitrogen containing compounds as discussed in the NACs section  
373 below. This suggests that the composition of a portion of SOA produced in the presence of NO<sub>x</sub> is different than that  
374 formed in the absence of NO<sub>x</sub>, which can be clearly illustrated by the filters and extracts color shown in Figure 2 (bottom).  
375 Consistent with the presence of nitroaromatics, filter F2 and methanol extract (E2) has lost most of the color seen in F1  
376 and E1. The presence of NO<sub>x</sub> in the system produced material (filter F1) of a deep brown color. Most species structurally  
377 identified in this study have not been reported in the literature, and mass spectra associated with several peaks are provided  
378 either in the main manuscript or in the SI. Additional reaction products (e.g., oligomers, organonitrates) might have been  
379 present in the SOA but could not be detected based on the analytical techniques used in this study. Note that formulae, in  
380 particular chemical structure, could not be obtained for several peaks recorded in this study due to challenges interpreting

381 their mass spectra. A set of compounds identified and detected before 28 min in the present study are summarized in  
382 Table 5.

383 Ring retaining products (e.g., 2-hydroxy benzyl alcohol, benzoic acid, 4-hydroxy benzoic acid, and catechol) were  
384 detected in the PP in both systems. As noted above, some ring-retaining products were detected also in the GP as shown  
385 in Table 5. Salicylaldehyde and 3-hydroxybenzaldehyde were present only in the GP. These two hydroxy-aldehydes may  
386 undergo additional secondary reactions leading to some ring-opening products observed in this study. Representative EI  
387 mass spectra of the TMS-derivatives associated with four compounds are shown in figure 3 including benzoic acid,  
388 benzene-1,2-diol (catechol), 4-hydroxybenzoic acid, and 2-hydroxybenzyl alcohol. Additional EI and CI mass spectra are  
389 shown in figures S4 and S5 in the SI. The EI mass spectrum of the BSTFA derivative of 2-hydroxybenzyl alcohol  
390 displayed in figure 3 shows abundant fragment ions at  $m/z$  73, 147, 267 ( $M^+$ ), 253 ( $M^+ - 15$ ), and 179 ( $M^+ - 89$ ), and  
391 weak ions at  $m/z$  91, 223 and 163. The corresponding CI mass spectrum displayed in figure S4d shows abundant fragment  
392 ions at  $m/z$  268 ( $M^+$ ), 253 ( $M^+ - 15$ ), and 179 ( $M^+ - 89$ ) and adduct ions at  $m/z$  293 ( $M^+ + 29$ ) and 309 ( $M^+ + 41$ ). This  
393 fragmentation pattern is consistent with the presence of a compound with two hydroxyl groups and a benzene ring ( $m/z$   
394 91) having molecular weight 268 for the BSTFA derivative, and MW 124 for its underivatized form. Similarly, the BSTFA  
395 EI mass spectrum of 4-hydroxybenzoic acid (Figure 3c) shows characteristic fragment ions at  $m/z$  73, 193 ( $M^+ - 89$ ), 223  
396 ( $M^+ - 60$ ), 267 ( $M^+ - 15$ ) and 282 ( $M^+$ ), and its CI mass spectrum fragment ions at  $m/z$  73, 193, 67 and adducts at 283,  
397 and 311. Again, these fragments and adducts are consistent with the presence of two (-OH) groups and a molecular weight  
398 of the derivatized compound of 282 and 138 for the underivatized compound. The presence of a peak at  $m/z$  153 ( $M^+ -$   
399 117) is consistent with a compound bearing an organic acid group. The EI mass spectra recorded in this study for 2-  
400 hydroxybenzyl alcohol and 4-hydroxybenzoic acid are identical to the reference NIST spectrum (webook.nist.gov). Figure  
401 S5 shows EI mass spectra associated with four peaks eluted at 12.86, 15.58, 16.24, and 19.78 min consistent with the  
402 fragmentation pattern of BSTFA derivatives, although their structures could not be obtained.

403 **Highly oxygenated compounds (HOCs).** Recent studies show that highly oxygenated compounds (e.g., HOMs) play an  
404 important role in understanding SOA formation (Berndt et al. 2016, Jaoui et al., 2019; 2021 and references therein, Piletic  
405 and Kleindienst, 2022). These compounds may result from several generations of atmospheric oxidation. In this study,  
406 several ring-opening products eluted late in the chromatograms ( $RT > 25$  min), with a relatively high O:C ratio of  $> 1.3$   
407 likely contributes to their condensation in the PP, were detected. Three groups of these oxidation products were detected

408 in the PP in both systems. Figure 4 shows the portion between 25 and 34 min of selected GC-MS extracted-ion  
409 chromatograms where these groups (color coded) elute and uses the selected ions  $m/z$  423, 437, and 525 (merged in one  
410 chromatogram) to best illustrate them: (a) BnOH/NO<sub>x</sub>; (b) BnOH/H<sub>2</sub>O<sub>2</sub>; (c) chamber background. Groups 1, 2, and 3  
411 consist of three (green), eight (blue) and four (red) peaks, respectively, and are completely absent from the background  
412 chromatogram (figure 4c). Results from a comprehensive interpretation of EI and CI mass spectra associated with peaks  
413 shown in figure 4 enabled the identification of several isomers associated with each group. Figure 5 displays three EI  
414 mass spectra associated with each group main peak, along with proposed structure and chemical formulae. Table 6 gives  
415 the major highly oxygenated compounds identified in this research, including the main peaks from each of these groups,  
416 in the order of their underivatized molecular weight. Table 6 gives the chemical formulas, O:C mass ratio, the five most  
417 abundant ions associated with each TMS derivative in methane-CI and EI modes, the molecular weights of the  
418 underivatized (MW) and TMS-derivatized compounds (MW<sub>BSTFA</sub>), and the proposed chemical structures of the  
419 compounds.

420 Group 1 consists of *meso*-tartaric acid (*mTA*) (Rt 26.04 min), and *L/D*-tartaric acids (*lTA/dTA*) (Rt 27.66 min)  
421 identified based on authentic standards. The mass spectra of BSTFA derivatives of *lTA* and *dTA* standards (Figure S6,  
422 SI) are very similar (eluting at the same time) and are only slightly different from the *mTA* (Figure S6: SI); however,  
423 *lTA/dTA* and *mTA* elute at two different retention times (Figure 4, S6). The peak associated with *mTA*, and *lTA/dTA* are  
424 among the largest peak observed in this portion of the chromatograms. Note, *lTA* isomer is the most abundant tartaric  
425 acid present in nature (DeBolt et al., 2006). The fragments and adducts observed for the peak eluting at 25.19 min are  
426 similar to those of *mTA* and *d-lTA* and are consistent with the presence of four OH groups, a MW of 452 for the  
427 derivatized compound and 164 for the underivatized compound, and a C<sub>4</sub>H<sub>6</sub>O<sub>6</sub> chemical formula. Tartaric acid has been  
428 reported in ambient aerosol (Rohrl and Lammel, 2002; Gowda et al., 2016) and in chamber 1,3-butadiene SOA (Jaoui et  
429 al., 2014). Recent studies suggest that tartaric acid and other hydroxy carboxylic acids undergo heterogeneous OH reaction  
430 in aqueous solution, with the presence and position of OH group(s) playing an important role in fragmentation and  
431 functionalization of organic aerosol (Cheng et al., 2016).

432 Group 2 consists of eight peaks (figure 4: blue) eluting between 28.5 and 31.5 min. The EI and CI mass spectra  
433 associated with each peak display similar fragment and adduct ions across the range of 50 to 600 Da. The interpretation  
434 of these mass spectra allows us to infer the molecular weight (MW) of the underivatized compounds as 164 and MW<sub>BSTFA</sub>  
435 of 452 for the TMS derivatives. The BSTFA CI mass spectrum of the peak eluted at 29.48 (largest peak) shows

436 characteristic fragment ions at  $m/z$  73, 437  $[M^+ - 15]$ , 363  $[M^+ - 89]$ , and 305  $[M^+ - 105]$ , and an adduct at 453  $[M^+ + 1]$ ,  
437 481  $[M^+ + 29]$ , and 493  $[M^+ + 41]$ . These fragments and adducts are consistent with the presence of four OH groups and  
438 an MW of 452 for the derivatized compound and 164 for the underivatized compound. The presence of peaks at  $m/z$  347  
439  $[M^+ - 105]$ , and 335 ( $M^+ - 117$ ) are consistent with a compound bearing alcoholic and carboxylic OH groups  
440 simultaneously. This mass spectrum is similar to the one from methyltartaric acid reported previously from isoprene  
441 oxidation by our group (Jaoui et al., 2019). The silylated methyltartaric acid mass spectrum (Jaoui et al., 2019) and mass  
442 spectra associated with group 2 are only slightly different, however, they elute at different retention times. The peaks have  
443 been tentatively identified as isomers of trihydroxy-oxo-pentanoic acid, with the structure of 4-oxo-D-arabonic acid  
444 isomer shown in Table 6.

445 Group 3 consists of four peaks eluting between 32.5 and 34 min (figure 4: red). The EI and CI mass spectra associated  
446 with each peak display similar fragment and adduct ions across the range of 50 to 600 Da. As a descriptive example, an  
447 EI mass spectrum is shown in Figure 5 for peak eluted at 33.1 min. A comprehensive interpretation of EI and CI mass  
448 spectra associated with group 3 peaks (Figures 4, 5), allows us to infer the molecular weight (MW) of the underivatized  
449 compounds as 180, and  $MW_{BSTFA}$  of 540 for the TMS derivatives, with a chemical formulae  $C_5H_8O_7$ . The compounds  
450 corresponding to these four peaks were identified as isomers of  $C_5$ -trihydroxydicarboxylic acids. This identification is  
451 tentative due to the absence of authentic standards, except for peak eluting at 33.47, which was identified as pentaric acid  
452 (Table 6) based on authentic standard. The spectra of BSTFA derivatives of the remaining three red peaks are only slightly  
453 different from the pentaric acid spectrum (Figure 6); however, they elute at different retention times. The EI mass spectra  
454 are also similar to those reported in the literature for a set of  $C_5$ -aldaric acids-TMS derivatives including xylaric, arabinaric  
455 and ribaric acids (Hinton et al., 2008; <https://pubchem.ncbi.nlm.nih.gov>). Figure 6 shows the structure of pentaric acid  
456 and its four isomers (a), the spectra associated with BSTFA derivative of pentaric acid observed in BnOH SOA (b: EI  
457 mode), (c: CI- $CH_4$  mode), and standard (d: EI mode). Figure 6 also shows the structure of the main fragments observed  
458 in BSTFA derivative of pentaric acid in EI mode including  $m/z$  at 540, 525, 407, 292, 147, and 73 Da. Pentaric acid and  
459 its isomers (aldaric acids) are reported to be formed from the oxidation of aldopentose (Hinton, 2008; Derrien et al., 2018),  
460 but no evidence has been provided for its presence in SOA samples. In the present study, we successfully identified aldaric  
461 acids from the oxidation of BnOH in SOA samples.

462

463 **Nitroaromatic compounds (NACs).** NACs of secondary origin are a possible contributor to urban OA and not only  
464 adversely affect human health and the environment but impact the aerosol optical properties and the atmospheric radiation  
465 balance. By understanding the sources of NACs in ambient particles and their chemical identities, we can evaluate their  
466 impact on the climate, environment, and human health. Recently, the analytical capabilities associated with BSTFA  
467 derivatization have been extended to NACs bearing hydroxyl and carboxylic acid groups (Jaoui et al., 2018). Mass spectra  
468 of most silylated NACs, especially methane-CI, are highly specific, reproducible, and produce characteristic fragments  
469 useful in determining structural information and molecular weight, when authentic standards are not available (Jaoui et  
470 al., 2018). In this study, a detailed analysis of mass spectra associated with peaks in chromatograms Figure 1c (GP) and  
471 Figure 2 top (PP) reveals the presence of several peaks presenting similar fragmentation patterns as those reported by  
472 Jaoui et al. (2018) for species bearing hydroxyl, carboxylic, nitro groups, and benzene ring. Figure 7 shows the portion  
473 between 23 and 42 min of two +EI extracted ion chromatograms for the BSTFA derivatives at  $m/z$  210, 165 (IS), 299 (IS),  
474 300, 298, 372, 388 (merged in one chromatogram) associated with BnOH/NO<sub>x</sub> (top) and BnOH/H<sub>2</sub>O<sub>2</sub> (bottom). The EI  
475 and/or CI mass spectra of selected nitroaromatic standards can be found in Jaoui et al. (2018), and additional representative  
476 subset of the derivatives are displayed in Figures S7 (SI). For clarity, figure 7 inset shows an expanded portion of the top  
477 chromatogram between 26.7 – 28 min. Table 7 contains proposed identification of NACs detected in this study, along  
478 with molecular weights, formulae, main 5 intense ions associated with CI and EI mass spectra of the derivatives, proposed  
479 structure, and the GP to PP peak area ratio.

480 NACs with the highest confidence assignment are those identified by comparing their retention times, EI, and CI  
481 mass spectra with those of reference standards, and NACs with low levels of confidence are those (1) that have been  
482 identified previously in ambient PM or in smog chamber studies, (2) their EI mass spectra exist in the literature, or (3)  
483 their molecular weights and numbers of OH, COOH, and NO<sub>2</sub> groups are simply consistent with the CI and EI mass  
484 spectrum (Jaoui et al., 2018). A total of fourteen peaks associated with NACs were detected in this study. 3-Nitrobenzyl  
485 alcohol, 4-nitrocatechol, 2-hydroxy-5-nitro benzyl alcohol, and 2-nitrophenol were identified based on authentic  
486 standards. Three peaks eluted at 33.76, 34.70, and 34.76 having similar mass spectra as 2-nitrophenol (main peak)  
487 eluted at 35.62 min were detected. They were tentatively associated with homologous series of 2-nitrophenol  
488 including 3-nitrobenzene-1,2,4-triol, 5-nitropyrogallol, and 4-nitro-1,2,3-benzenetriol (not shown in Table 7). Similarly,  
489 three additional peaks having similar mass spectra as 2-hydroxy-5-nitrobenzyl alcohol were observed and were tentatively  
490 associated with homologous series of 2-hydroxy-5-nitrobenzyl alcohol including 4-hydroxy-2-nitrobenzyl alcohol. The

491 EIC in figure 7 (top) includes a series of four peaks observed only in the PP eluting at 35.94, 36.60, 38.18 min, whose  
492 mass spectra were consistent with the presence of molecular weight 185 and 401 for the underivatized and derivatized  
493 compounds, respectively. Based on similarity of their mass spectra, they were tentatively identified as structural  
494 homologue of 3,4-dihydroxy-5-nitrobenzyl alcohol (Table 7) with  $C_7H_7NO_5$  formulae. As can be seen in figure 7 (bottom),  
495 NACs peaks were not detected in BnOH/H<sub>2</sub>O<sub>2</sub> SOA extract, consistent with the formation of NACs in the presence of  
496 NO<sub>x</sub>. All NACs were detected in both GPs and PP (Table 7), except 2-nitrophenol and 3,4-dihydroxy-5-  
497 nitrobenzyl alcohol and their isomers were observed only in the PP consistent with their low volatility. This result suggests  
498 that NACs may be formed in the GP, and partition to the PP for those with low volatility, although PP reactions may  
499 occur as suggested by Charan et al. (2020) who analyzed only PP. 4-Nitrocatechol and 2-nitrophenol were among  
500 the largest NAC peaks observed in our study (Figure 7). All three experiments conducted in this study were analyzed for  
501 NACs to probe reproducibility of the BSTFA method and showed consistent results. 2-Nitrophenol, 4-  
502 nitrocatechol and other NACs has been reported in PM collected in Pico Mountain Observatory, Pico Island in the Azores  
503 archipelago by Ikemori et al., (2019). A series of NACs have been reported recently by Charan et al. (2020) in BnOH  
504 SOA using off-line UPLC/ESIQ-ToFMS (ultra-high-performance liquid chromatography electrospray ionization  
505 quadrupole time of flight mass spectrometry), and the structure assigned to formulas obtained from MassLynk software  
506 was based on expected oxidation products and MS/MS analysis. These observations support the identification of NACs  
507 reported in this study. 4-Nitrophenol was reported in the GP by Bernard et al., (2013) at low yield and by Charan et al.  
508 2020 in SOA from the OH radical oxidation of BnOH but was not detected either in the GP or the PP in this study.

509

### 510 **3.3. Mechanism of product formation**

511 Based on known GP reactions for aromatic compounds, a schematic representation for the reaction of BnOH with OH is  
512 presented in schemes 1-3. It is developed to understand the chemistry leading to the main GP and PP products identified  
513 experimentally in this study including HOCs and NACs. These schemes incorporate the latest experimental, quantum and  
514 kinetic developments of the fate of peroxy/alkoxy benzoyl radicals including autooxidation (Wang, 2015; Sankar et al.  
515 2014, and Namysl et al. 2020). The lines shown in these schemes are either one step or multistep pathways. Rate constants  
516 at room temperature of BnOH with OH radical, O<sub>3</sub>, and NO<sub>3</sub> radical of  $2.8 \times 10^{-11}$ ,  $6 \times 10^{-19}$  (upper limit), and  $4.0 \times 10^{-15}$   
517 cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup>, respectively, have been reported in the literature (Harrison and Wells, 2009, 2012; Bernard et al.,  
518 2013). This suggests that the day-time oxidation of BnOH will be mainly initiated by OH radicals. The reaction for O<sub>3</sub>

519 and NO<sub>3</sub> radical are not included in schemes 1-3, although they are expected to be formed as minor products in our  
520 systems. Ozone is known to react primarily with compounds having double bonds and certainly not aromatic compounds.  
521 Ozone concentrations are low and given in Table 2. Likewise, the NO<sub>3</sub> reaction with aromatic compounds tends to be  
522 very slow and unlikely to have any impact in these systems. Moreover, given the O<sub>3</sub> + NO<sub>2</sub> reaction which gives NO<sub>3</sub>  
523 would only react with BnOH to a negligible degree.

524 The reaction of BnOH with OH radicals is initiated primarily by H atom abstraction from the external CH<sub>2</sub> group  
525 leading to BnAld, and OH addition to the aromatic *ipso* (C1) and *ortho* (C2 or C6) positions to form two  
526 alkyldihydroxyadducts R1 and R2 (scheme 1). The OH addition to the *para* (C3, C5) and *meta* (C4) position was reported  
527 to be not favourable based on theoretical study of Wang, (2015). Scheme 1 shows mechanistic pathways leading to the

528

529

530

**Scheme 1.** Initial reaction pathways proposed to produce selected products detected in this study (blue color) in the gas

531

or PP (Table 5). R1-2600 and R2-1300 intermediates undergo further reactions leading to ring-opening products as

532

shown in scheme 3.

533 formation of stable products (blue) including BnAld, 4-hydroxybenzyl alcohol, 2-hydroxybenzyl alcohol, phenol,  
534 formaldehyde, and catechol. The initial branching ratios shown in scheme 1 are those reported by Wang (2015), obtained  
535 by combining quantum chemistry calculations and experimental work from the literature. BnAld was observed in this  
536 study in the presence and absence of NO<sub>x</sub>, and its secondary chemistry may lead in part to oxygenated compounds  
537 observed in this study (Bernard et al., 2013). Due to large number of possible intermediates formed (Wang, 2015), only  
538 selected pathways energetically favourable leading to some products observed in this study are considered. We refer the  
539 readers to Wang (2015) paper for an in-depth theoretical analysis of mechanistic pathways leading to the formation of  
540 selected reaction products. The adduct R1 reacts rapidly through addition of O<sub>2</sub> to the ortho (C2) to produce peroxy  
541 radicals R1-2OO, The O<sub>2</sub> addition to para position (C4) leading to R1-4OO peroxy radicals (not shown in Scheme 1) was  
542 found to be endothermic, therefore negligible (Wang, 2015). Radicals R1-2OO undergo intramolecular H-shifts or ring  
543 closures to form a stable bicyclic intermediate R1-26OO (red). Similarly, R2 reacts rapidly with O<sub>2</sub> to form peroxy radical  
544 R2-1OO intermediate, which itself undergoes intramolecular H-shifts or ring closures to form a stable bicyclic  
545 intermediate R2-13OO (red). R1-26OO and R2-13OO intermediates undergo further reactions leading to ring-opening  
546 products as shown in scheme 3 below. 2-Hydroxybenzyl alcohol was proposed by Wang (2015) to form through the  
547 reaction of R2 with O<sub>2</sub> involving rapid direct H-abstraction. A possible formation pathway of phenol is decomposition of  
548 the peroxy radicals R1-2OO and R2-1OO through CH<sub>2</sub>OH radical elimination (Bernard et al., 2013). As in Wang (2015),  
549 the reverse reaction that gives R1 + O<sub>2</sub> is certainly competitive with the cyclization. Moreover, this reversible reaction  
550 sustains the concentration of R1 with the radical now delocalized within the aromatic structure rather than associated with  
551 the substituent O<sub>2</sub>. By this approach, reactions of R1 lead to the formation of phenol and subsequent formation of catechol  
552 as shown in Scheme 1. However, we do not have quantitative product data that would give insight to the R1-2OO and  
553 R2-1OO decomposition (reverse) rate with respect to the O<sub>2</sub>-cyclization rate. Note that the R1 reaction to form the phenol  
554 is independent of NO<sub>2</sub> whereas the reaction of R1 to form nitrobenzyl alcohol is dependent on NO<sub>2</sub>.

555 CH<sub>2</sub>OH radical reacts rapidly with O<sub>2</sub> to produce formaldehyde. Catechol was proposed to originate from the reaction of  
556 OH radicals with phenol (Atkinson et al., 1992) and with 2-hydroxybenzyl alcohol (Bernard et al., 20013).

557 NACs observed in this study (Table 7) are expected to be formed through reaction of OH radicals with BnOH in the  
558 presence of NO<sub>2</sub>. Scheme 2 briefly summarizes the main mechanistic pathways leading to BnOH NACs, which follow  
559 similar chemistry as those reported for toluene, benzene, and xylenes (Jenkin et al., 2003; Vidovic et al., 2018) and  
560 summarized by Wang et al., (2019). The steps shown in scheme 2 are multi-steps and the reader should consult the

561 reference papers above for more in depth information. NACs are proposed to originate from secondary reactions of  
562 catechol, 1,3,5-trihydroxy benzene, and 4-hydroxybenzyl alcohol with OH radicals in the presence of NO<sub>2</sub> (scheme 2).  
563 These intermediates are proposed to be originated from R1, R2, and R3 adducts. Additional pathways could be initiated  
564 via less well understood aqueous-phase nitration (Kroflíc et al., 2018). 4-Nitrocatechol is proposed to be initiated through  
565 the reaction of catechol with OH radicals in the presence of NO<sub>x</sub> (Finewax et al., 2018). 4-Hydroxy-2-nitrobenzyl alcohol  
566 is proposed to be likely originated from the alkyldihydroxy-para-adduct formed from the OH addition to para position  
567 (scheme 2). 2-Nitrochloroglucinol and 3,4-dihydroxy-5-nitrobenzyl alcohol follow similar reactions involving R3 adduct,  
568 OH radicals, and NO<sub>2</sub>.

569 According to Wang (2015) calculation, at high NO<sub>2</sub> (100 ppbv) the reaction of R1 with NO<sub>2</sub> can compete to a minor  
570 degree with the reaction with O<sub>2</sub>, therefore R1 possibly forms minor amounts of nitrobenzyl alcohol. This is similar to  
571 that of other alkylbenzenes, such as toluene, although at much higher NO<sub>2</sub> concentrations (Wang, 2015). According to  
572 the Wang calculation at 100 ppb NO<sub>2</sub>, up to 30% of the R1 radical can form nitrobenzyl alcohol (unspecified nitro location  
573 on the ring). When including the R2 radical which forms negligible levels of nitrobenzyl alcohol, no more than 20% (and  
574 likely much less under our conditions) of the initial ring retaining radical would form nitrobenzyl alcohol. As noted in the  
575 caption to table 1, the initial NO<sub>x</sub> is 98% NO and thus there is an extremely low initial concentration of NO<sub>2</sub>. As the  
576 extent of reaction increases, the NO<sub>y</sub> concentration increases as do other more oxidized forms of NO<sub>x</sub>. Thus, the addition  
577 of NO<sub>2</sub> (~100 ppb) to the carbon-centered radical on the ring is of the same order as that described by Wang (2015) as  
578 being of minor importance compared to O<sub>2</sub> addition. Thus, even though NO<sub>y</sub> concentrations in these experiments are  
579 higher than ambient concentrations, we consider the findings and mechanisms of Wang (2015) to be relevant to this work.  
580 We only have an upper limit to the NO<sub>2</sub> concentration, that is, NO<sub>y</sub>-NO. NO<sub>y</sub> represents in the NO<sub>x</sub>-NO from the oxides  
581 of nitrogen (NO<sub>x</sub>) monitor. It is well known that the NO<sub>x</sub> monitor in the NO<sub>x</sub>-NO channel measures other oxidized  
582 organic compounds in addition to NO<sub>2</sub>.

583

584

585

586 **Scheme 2.** Proposed mechanism for selected NAC species observed in this study.

587

588 HOCs were detected in the PP from the oxidation of BnOH in both low and high NO<sub>x</sub> systems (Table 6). Mechanistic

589 pathways based on theoretical studies leading to several HOCs (e. g. HOMs) from the atmospheric oxidation of biogenic

590 and aromatic hydrocarbons have been reported recently in the literature involving unimolecular reaction through

602 proposed to be formed through the oxidation of butenedial and/or 2,3-epoxybutanal through classical oxidation of  
603 aldehydes and alkenes to carboxylic acid (not shown in scheme 3). Similarly, 2,3,5-trihydroxy-4-oxo-pentanoic acid and  
604 pentaric acid are proposed to arise from the oxidation of 5-hydroxy-4-oxo-2-pentenal, and 4-hydroxy-2,3-  
605 epoxy-pentanedial, respectively following similar mechanistic pathways reported by Jaoui et al. (2021) for the formation  
606 of methyltartaric acid from 4-hydroxy-2-methyl-but-2-enal involving peroxy and alkoxy radical isomerization (not  
607 reported here). In this study, a new mechanism is proposed in scheme 3 leading to the formation of 4-hydroxy-2,3-  
608 epoxy-pentanedial, which is the starting material for pentaric acid formation. It involves several intermediate steps  
609 including unimolecular H migration (e.g., 1,5-H shift), ring opening and decomposition. Formaldehyde and glyoxal  
610 observed in this study are also shown in scheme 3. The data used to support the secondary reactions of R2-13OO is  
611 primarily product data shown in Scheme 3 which shows fragmentation products from R2-13OO. These products have  
612 been well known for alkylbenzenes for many years. We have used analogous pathways for these alkylbenzenes to provide  
613 an understanding as to how observed fragmentation products of BnOH are formed. However, it is important to note that  
614 these fragmentation pathways follow from the formation of alkoxy radicals and not peroxy radicals. Thus, NO is required  
615 in the system. (Note:  $RO_2 + RO_2 \rightarrow 2RO + O_2$  is too slow to provide the alkoxy radicals needed for the fragmentation  
616 reaction to occur.) Similar pathways are also applicable for R1-26OO.

617

#### 618 **4. Summary**

619 In the present manuscript, laboratory experiments were conducted to investigate SOA formation from the oxidation  
620 of benzyl alcohol in the presence and absence of NO<sub>x</sub>. Chamber aerosol collected under these conditions has been  
621 analyzed for organic mass to organic carbon ratio, and aerosol yield. In addition, the chemical composition of the gas  
622 phase and SOA was analyzed using derivative-based methods followed by gas chromatography-mass spectrometry and  
623 high-performance liquid chromatography analysis of the derivative compounds. More than 50 oxygenated organic  
624 compounds in the gas and particle phases were identified. While a detailed non-targeted analysis has been made, our  
625 primary focus has been to examine highly oxygenated and nitroaromatic compounds. The major components include ring-  
626 opening products with high oxygen to carbon ratio (e. g. malic acid, tartaric acid, arabic acid, 2,3,5-trihydroxy-4-oxo-  
627 pentanoic acid, and pentaric acid) and ring-retaining products (e. g. benzaldehyde, benzoic acid, catechol, 3-nitrobenzyl  
628 alcohol, 4-nitrocatechol, 2-hydroxy-5-nitrobenzyl alcohol, 2-nitrophenol, 5-(hydroxymethyl)- 3-nitro-1,2-benzyl  
629 diol). The presence of some of these products in the gas and particle phases simultaneously provides evidence of their

630 gas/particle partitioning. These oxygenated oxidation products made dominant contributions to the SOA particle  
631 composition in both low and high NO<sub>x</sub> systems. Yields, organic mass to organic carbon ratio, and proposed reaction  
632 schemes for selected compounds are provided.

633 Finally, a set of reaction pathways are proposed that accounts for selected reaction products observed in this study  
634 from BnOH photooxidation in the presence of OH radicals, including NACs and HOCs. The proposed mechanism is  
635 based on (1) theoretical studies reported previously in the literature and (2) mechanisms associated with aromatics  
636 oxidation (e.g., benzene, toluene, xylenes...). New pathways were proposed for the formation of newly observed highly  
637 oxygenated compounds tartaric acid, 2,3,5-trihydroxy-4-oxopentanoic acid, and pentaric acid. Butenedial/2,3epoxy-  
638 butandial, 5-hydroxy-4-oxo-2-pentenal, and 4-hydroxy-2,3-exopentanedial were proposed as the starting intermediate  
639 species leading to these highly oxygenated compounds. While theoretical studies involving unimolecular reactions were  
640 developed focusing mainly on ring-containing products (Wang, 2015, Piletic and Kleindienst, 2022), similar theoretical  
641 investigations focusing on linear species (Jaoui et al., 2021) as HOCs reported in this study will help strengthen the  
642 pathways proposed here.

643 The results of this study potentially have atmospheric implications for areas impacted by benzyl alcohol including  
644 urban and indoor areas and contribute to understanding the formation of ambient SOA from oxygenated anthropogenic  
645 precursors. Nitroaromatics are pollutants of concern due to their toxicity, light-absorption properties, and relatively long  
646 residence times in the environment. HOCs may partition into pre-existing particles or be involved in new particle  
647 formation.

1006 **Table 5.** Summary of selected reaction products detected and identified either in gas-phase (GP), particle phase (PP) or  
 1007 both from BnOH/NO<sub>x</sub>, and BnOH/H<sub>2</sub>O<sub>2</sub> experiments. Tables 6 and 7 shows additional aerosol species with high oxygen  
 1008 to carbon ratio and/or nitro group. NA: not applicable. \*: underivatized m/z are given. \*: identified with authentic standard.

IUPAC/common nomenclature	Formula	m/z BSTFA (EI)	MW [MW <sub>BSTFA</sub> ] (g mol <sup>-1</sup> )	Proposed Structure	Detected
Benzyl alcohol (BnOH)	C <sub>7</sub> H <sub>8</sub> O	165, 91, 135, 180, 73	108 [180]		GP
Phenol	C <sub>6</sub> H <sub>6</sub> O	73, 151, 166, 94, 65	94 (166)		GP, PP
Benzaldehyde (BnAld)	C <sub>7</sub> H <sub>6</sub> O	106, 105, 77, 77, 51	106 (NA)		GP, PP
Benzene-1,2-diol (catechol)	C <sub>6</sub> H <sub>6</sub> O <sub>2</sub>	239, 255, 80, 283, 73	110 (254)		PP
Benzoic acid	C <sub>7</sub> H <sub>6</sub> O <sub>2</sub>	179, 105, 135, 77, 194	122 (194)		GP, PP
Salicylaldehyde	C <sub>7</sub> H <sub>6</sub> O <sub>2</sub>	179, 105, 135, 77, 194	122 (194)		GP
3-Hydroxy benzaldehyde	C <sub>7</sub> H <sub>6</sub> O <sub>2</sub>	179, 105, 135, 77, 194	122 (194)		GP
2-Hydroxybenzyl alcohol (salicyl alcohol)	C <sub>7</sub> H <sub>8</sub> O <sub>2</sub>	73, 253, 179, 268, 147	124 (268)		GP, PP
4-Hydroxybenzyl alcohol	C <sub>7</sub> H <sub>8</sub> O <sub>2</sub>	73, 179, 253, 268, 147	124 (268)		GP, PP
4-Hydroxybenzoic acid ( <i>p</i> -salicylic acid)	C <sub>7</sub> H <sub>6</sub> O <sub>3</sub>	267, 223, 193, 282, 73	138 (282)		PP [H <sub>2</sub> O <sub>2</sub> ]

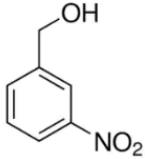

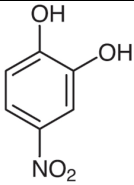

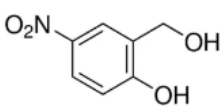

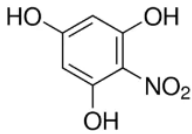

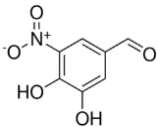

1009

1010 **Table 6.** Highly oxygenated products (O:C > 1.3) identified in benzyl alcohol photooxidation in the presence of NO<sub>x</sub>, or  
 1011 H<sub>2</sub>O<sub>2</sub>. \*: identified with authentic standard. *L*-Tartaric acid and *D*-tartaric acid co-elute. The structure of 4-oxo-*D*-arabonic  
 1012 acid isomer and 2,3,5-Trihydroxy-4-oxopentanal isomer are shown for trihydroxy-oxo-pentanoic acid, and trihydroxy-  
 1013 oxo-pentanal, respectively. Four peaks with similar fragments/adducts as pentaric acid were observed.

Nomenclature	Chemical Formulae	O/C Ratio (by wt)	<i>m/z</i> BSTFA Derivative (CI-CH <sub>4</sub> ); (EI)	MW (MW <sub>BSTFA</sub> )	Proposed Structure
Epoxy succinic acid (2 peaks)	C <sub>4</sub> H <sub>4</sub> O <sub>5</sub>	1.7	187, 261, 73, 277, 173 73, 173, 261, 129, 143	132 (276)	
2-Hydroxybutanedioic acid* (malic acid)	C <sub>4</sub> H <sub>6</sub> O <sub>5</sub>	1.7	233, 335, 73, 307, 351 73, 147, 233, 245, 335	134 (350)	
Trihydroxy-oxo-pentanal (5 peaks)	C <sub>5</sub> H <sub>8</sub> O <sub>5</sub>	1.3	73, 275, 203, 349, 393 147, 73, 349, 233, 259	148 (364)	
<i>meso</i> -Tartaric acid*	C <sub>4</sub> H <sub>6</sub> O <sub>6</sub>	2.0	423, 321, 277, 439, 73 73, 147, 292, 219, 423	150 (438)	
<i>L</i> -Tartaric acid*	C <sub>4</sub> H <sub>6</sub> O <sub>6</sub>	2.0	423, 321, 277, 439, 73 73, 147, 292, 219, 423	150 (438)	
Trihydroxy-oxo-pentanoic acid (8 peaks)	C <sub>5</sub> H <sub>8</sub> O <sub>6</sub>	1.6	73, 437, 363, 481, 493 217, 73, 147, 437, 292	164 (452)	
<i>D</i> -Arabinonic acid* (Arabic acid)	C <sub>5</sub> H <sub>10</sub> O <sub>6</sub>	1.6	361, 217, 73, 435, 525 204, 437, 73, 147, 319	166 (526)
