Abstract

The Amazon Basin is frequently influenced by the trans-Atlantic transport of African dust plumes during its wet season (January – April), which not only interrupts the near-pristine atmospheric condition in that season, but also provides nutrient inputs into the Amazon rainforest upon deposition. In this study, we use the chemical transport model GEOS-Chem to investigate the impact of the export of African mineral dust to the Amazon Basin during the period of 2013 – 2017, constrained by multiple datasets obtained from AERONET, MODIS, as well as Cayenne site and the Amazon Tall Tower Observatory (ATTO) site in the Amazon Basin. With optimized particle mass size distribution (PMSD) of dust aerosols, the model well captures observed AOD regarding both the mean value as well as the decline rate of the logarithm of AOD over the Atlantic Ocean along the transport path (AOaTP), implying the consistence with observed export efficiency of African dust along the trans-Atlantic transport. With an annual emission of $0.73 \pm 0.12 \text{ Pg yr}^{-1}$, African dust entering the Amazon Basin has surface concentrations of $5.7 \pm 1.3 \mu\text{g m}^{-3}$ (up to 15

35 $\mu\text{g m}^{-3}$ in the northeast corner) during the wet season, accounting for $40\% \pm 4.5\%$ (up
36 to 70%) of mass concentrations of total aerosols. Observed dust peaks over the
37 Amazon Basin are generally associated with relatively higher African dust emissions
38 (including Sahara and Sahel) and longer lifetime of dust along the trans-Atlantic
39 transport, namely higher export efficiency of African dust across the Atlantic Ocean.
40 The frequency of dust events in the Amazon Basin in the wet season is around 18%
41 averaged over the basin, with maxima over 60% at the northeast coast. During the
42 dust events, AOD over most of the Amazon Basin is dominated by dust. Associated
43 with dust deposition, we further estimate annual inputs of 52 ± 8.7 , 0.97 ± 0.16 and 21
44 $\pm 3.6 \text{ mg m}^{-2} \text{ yr}^{-1}$ for iron, phosphorus and magnesium deposited into the Amazon
45 rainforest, respectively, which may well compensate the hydrologic losses of nutrients
46 in the forest ecosystem.

47

48 **1 Introduction**

49 The desert over North Africa, being the world's largest dust source, contributes to
50 over 50% of global dust emission (Kok et al., 2021; Wang et al., 2016). Dust particles
51 are uplifted by strong surface winds, and then typically transported downwind for a
52 long distance, reaching Atlantic, Caribbean, America, and Europe (Prospero et al.,
53 1981; Ben-Ami et al., 2012; Yu et al., 2019; Swap et al., 1992; Prospero et al., 2014;
54 Wang et al., 2020). The emission varies on daily to seasonal and even decadal time
55 scales, largely affected by local wind speed, land surface cover, soil moisture, etc
56 (Ridley et al., 2014; Mahowald et al., 2006). Once present in the atmosphere, mineral
57 dust can degrade air quality downwind as well as modify the atmospheric radiative
58 balance via directly scattering and absorbing solar radiation (Ryder et al., 2013b), and
59 altering cloud properties by acting as cloud condensation nuclei or ice nuclei (Chen et
60 al., 1998; Demott et al., 2003; Mahowald and Kiehl, 2003; Dusek et al., 2006).
61 Additionally, mineral dust contains iron, phosphorous, and other nutrients, and could
62 affect ocean biogeochemistry and fertilize tropical forest upon downwind deposition
63 (Niedermeier et al., 2014; Rizzolo et al., 2017).

64 There is an increased concern about the impact of African dust exerted over the
65 Amazon basin, which being the world's largest rainforest, represents a valuable but
66 also vulnerable ecosystem, and is sensitive to any disturbance from climate changes
67 associated with human activities in the future (Andreae et al., 2015; Pöhlker et al.,
68 2019). During the wet season (January – April) Amazonian aerosols are generally
69 dominated by local biogenic aerosol, with remarkably low PM₁₀ mass concentrations
70 of a few $\mu\text{g m}^{-3}$ (Andreae et al., 2015; Martin et al., 2010a; Prass et al., 2021). The
71 near-pristine condition, however, is frequently interrupted by the transatlantic
72 transport of African dust toward the Amazon Basin (Andreae et al., 2015; Martin et
73 al., 2010b; Martin et al., 2010a; Talbot et al., 1990). The dusty episodes could
74 drastically increase the aerosol optical depth (AOD, by a factor of 4), mass
75 concentrations of coarse aerosol (with diameter $> 1 \mu\text{m}$, up to $100 \mu\text{g m}^{-3}$), as well as
76 crustal elements over the Amazon Basin (Ben-Ami et al., 2010; Pöhlker et al., 2019;
77 Moran-Zuloaga et al., 2018; Baars et al., 2011; Formenti et al., 2001). Therefore, there
78 is great interest in understanding factors controlling the export of African dust towards
79 the Amazon Basin and the impact they might have on the environment, ecosystem,
80 and climate.

81 Over the past decades, field measurements combined with satellite observation and
82 forward/back trajectory analysis have been conducted to explore the long-range
83 transport (LRT) of African dust toward the Amazon Basin (e.g. Ben-Ami et al., 2010;
84 Pöhlker et al., 2018; Prospero et al., 2020). The transatlantic transport of African dust
85 plumes is closely related to annual north-south oscillation of the intertropical
86 convergence zone (ITCZ) (Moran-Zuloaga et al., 2018; Ben-Ami et al., 2012),
87 favoring the path towards the Amazon Basin in the late boreal winter and spring
88 (December-April) as the ITCZ moves southward. In addition to the annual oscillation
89 of ITCZ, the export efficiency of African dust towards the Amazon Basin also highly
90 depends on the lifetime of mineral dust, which is largely affected by the
91 meteorological condition (e.g. precipitation). Dust particles are subject to wet removal
92 when they are within or underneath precipitating clouds. For instance, Yu et al. (2020)

93 argued that El Djouf, in western Sahara, contributes more dust to the Amazon Basin
94 than the Bodélé depression as the transport paths of dust released from El Djouf are
95 less affected by the rainy cloud.

96 Besides meteorological conditions, dust size distribution can also influence its
97 lifetime and consequently the export efficiency of African dust towards the Amazon
98 Basin. Previous studies have observed that volume/mass fractions of coarse mode dust
99 particles, giant particles in particular, tend to be reduced along the transport due to
100 higher gravitational settling velocities (Ryder et al., 2018; Ryder et al., 2013b; Ryder
101 et al., 2013a; Van Der Does et al., 2016). Moreover, the optical properties of mineral
102 dust are also strongly size dependent, especially for those in sub-micron range (Liu et
103 al., 2018; Di Biagio et al., 2019; Ysard et al., 2018). For instance, Ryder et al. (2013a)
104 reported a loss of 60 – 90% of particles with diameter $> 30 \mu\text{m}$ 12 h after uplift and
105 consequently an increase in the single scattering albedo from 0.92 to 0.95 associated
106 with the change in the size distribution of dust aerosols. Therefore, the size
107 distribution of dust particles is a key factor determining the efficiency of dust
108 transport and consequently the environmental and climate effect of the mineral dust
109 downwind (Mahowald et al., 2011a; Mahowald et al., 2011b).

110 It is worth mentioning that the LRT events bring not only mineral dust into the
111 Amazon Basin but also biomass burning aerosols from Africa as well as sea spray
112 aerosols (Wang et al., 2016; Holanda et al., 2020; Andreae et al., 1990; Talbot et al.,
113 1990; Ansmann et al., 2009; Baars et al., 2011), making it challenging to have a
114 quantitative assessment of the impact of African dust on the Amazon Basin. So far, a
115 few studies have attempted to quantify the impact of the LRT of African dust over the
116 Amazon Basin, but mainly focus on dust deposition only (e.g. Yu et al., 2015a; Ridley
117 et al., 2012; Yu et al., 2019). Estimates of annual dust deposition and dust deposition
118 rates into the Amazon Basin exhibit a wide range ($7.7\text{-}50 \text{ Tg yr}^{-1}$ and $0.8\text{-}19 \text{ g m}^{-2} \text{ yr}^{-1}$,
119 respectively), attributed to the application of different methods and the intrinsic
120 uncertainties associated with each method (Kok et al., 2021; Yu et al., 2015b;
121 Kaufman, 2005; Swap et al., 1992). For example, the results based on Cloud-Aerosol

122 Lidar and Infrared Pathfinder Satellite Observations (CALIPSO) is subject to the
123 uncertainty associated with the Cloud-Aerosol Lidar with Orthogonal Polarization
124 (CALIOP) extinction, vertical profile shape, dust discrimination, diurnal variations of
125 dust transport as well as the below-cloud dust missed by CALIOP (Yu et al., 2015a).
126 While models could be considered as a useful tool to comprehensively assess the
127 transatlantic transport of African dust towards the Amazon Basin and the consequent
128 impact over the Amazon Basin, there exist considerable differences among model
129 results, attributed to the uncertainties associated with the dust parameterization in the
130 model, including emission schemes, dust size distribution, dust deposition, etc (Kim
131 et al., 2014; Huneus et al., 2011; Mahowald et al., 2014). Observational constraints
132 on the modelling results along the transport from source regions to receptor regions
133 are thus in urgent need to accomplish a better evaluation of factors controlling the
134 LRT of African dust and its overall impact over the Amazon Basin.
135 Here, we present a detailed multiyear simulation of the export of African dust across
136 the Atlantic and its impact over the Amazon Basin (around 8.8×10^6 km², see Figure
137 1 for defined area) during 2013 – 2017 with the GEOS-Chem (chemical transport
138 model). The aims of this study are: (1) to evaluate the model performance of dust
139 simulation including the particle mass size distribution (PMSD), optical properties,
140 mass concentrations as well as the export efficiency of African dust towards the
141 Amazon Basin; (2) to analyze factors controlling the export of African dust towards
142 the Amazon Basin; and (3) to give a comprehensive examination of the impact of
143 African dust over the Amazon Basin, including surface aerosol concentrations, AOD
144 and nutrient inputs upon deposition.

145

146 **2 Methodology**

147 **2.1 GEOS-Chem model**

148 **2.1.1 Model overview**

149 In this study we use the GEOS-Chem model version 12.0.0 (www.geos-chem.org) to
150 perform a global aerosol simulation with a horizontal resolution of $2^\circ \times 2.5^\circ$. The

151 GEOS-Chem is driven by assimilated meteorological data GEOS-FP from the NASA
152 Global Modeling and Assimilation Office (GMAO) (Lucchesi, 2013) with a native
153 horizontal resolution of $0.25^\circ \times 0.3125^\circ$, which is then degraded to $2^\circ \times 2.5^\circ$ for the
154 input to GEOS-Chem. We initialize the model with a 1-year spin-up followed by an
155 aerosol simulation from 2013 to 2017.

156 The aerosol simulation is an offline simulation for aerosol tracers including black
157 carbon (BC), organic aerosols (OA), and sulfate-nitrate-ammonium aerosols in fine
158 mode ($\leq 1 \mu\text{m}$ in diameter), sea salt in both fine and coarse ($> 1 \mu\text{m}$ in diameter)
159 modes, and mineral dust in four size bins covering the size range of $0.2 - 12 \mu\text{m}$ in
160 diameter. Aerosol optical properties used for aerosol optical depth (AOD) calculation
161 are mainly based on Global Aerosol Data Set (Koepke et al., 1997), with
162 modifications in aerosol size distributions (Jaeglé et al., 2011; Drury et al., 2010;
163 Wang et al., 2003a; Wang et al., 2003b), hygroscopic growth factor of organic
164 aerosols (Jimenez et al., 2009), and the refractive index of dust (Sinyuk et al., 2003).
165 AOD in the model is then calculated online at selected wavelengths assuming
166 lognormal size distributions of externally mixed aerosols and accounts for
167 hygroscopic growth (Martin et al., 2003).

168 Wet deposition in GEOS-Chem, based on the scheme of Liu et al. (2001), accounts for
169 scavenging in both convective updrafts and large-scale precipitation. Further updates
170 by Wang et al. (2011) are also applied, accounting for ice/snow scavenging as well as
171 the impaction scavenging in convective updrafts. Dry deposition in the model follows
172 the standard resistance-in-series scheme by Wesely (2007), accounting for turbulent
173 transfer and gravitational settling (Wang et al., 1998; Zhang et al., 2001).

174 **2.1.2 Dust emission and PMSD schemes in the model**

175 The emission of mineral dust is based on the dust entrainment and deposition (DEAD)
176 mobilization scheme of Zender et al. (2003) in the GEOS-Chem model. The DEAD
177 scheme calculates the total vertical dust flux based on the total horizontal saltation
178 flux (Q_s) using the theory of White (1979). The Q_s depends mainly on the surface
179 wind friction velocity and the threshold friction velocity, which is determined by soil

180 type, soil moisture content, and surface roughness. For more details of the DEAD
181 scheme, readers are referred to Duncan Fairlie et al. (2007).
182 Freshly emitted dust particles are divided into four size bins in GEOS-Chem: 0.1 –
183 1.0 μm , 1.0 – 1.8 μm , 1.8 – 3.0 μm , and 3.0 – 6.0 μm in radius. The first size bin is
184 further divided into four sub-bins (0.1 – 0.18 μm , 0.18 – 0.3 μm , 0.3 – 0.6 μm , and
185 0.6 – 1.0 μm in radius) for the calculation of optical properties. While total dust
186 emissions are not affected, optical properties, atmospheric lifetime and downwind
187 concentrations of dust particles are sensitive to different PMSD schemes. Table 1
188 shows 3 different PMSD schemes tested in this study: V12, V12_C and V12_F.
189 Scheme V12, which is derived based on scale-invariant fragmentation theory (Kok,
190 2011) with modification in tunable parameters (Zhang et al., 2013), is a default set in
191 GEOS-Chem. However, this scheme has been only evaluated for US/Asian dust, not
192 for Africa. On the other hand, V12_C was used in older versions of GEOS-Chem and
193 constrained from aircraft measurements during the Saharan Dust Experiment (Ridley
194 et al., 2012; Highwood et al., 2003). In addition, we derived V12_F based on the
195 measurements during the Fennec aircraft observations also focusing on Saharan dust.
196 Among all the three PMSD, V12_C has the largest mass fraction in the first bin
197 (relatively small particles) and the lowest fraction in the last bin (large ones). In
198 contrast, V12_F has the most dust distributed in the last bin ($\sim 70\%$) and only a little
199 (around 5%) in the first bin (0.1 – 1.0 μm). Simulated mass extinction efficiency
200 (MEE, also shown in Table 1) at wavelength of 550 nm for dust particles in the first
201 sub-bin (0.1 – 0.18 μm) is $3.13 \text{ m}^2 \text{ g}^{-1}$ and decreases to $0.16 \text{ m}^2 \text{ g}^{-1}$ for those in the last
202 bin (3.0 – 6.0 μm). The lifetime of dust aerosols against deposition are 5.1, 2.2, 1.7
203 and 0.86 d in the four bins (from small to large size), respectively. Therefore, although
204 with the same emission, total dust AOD, lifetime, and downwind concentrations could
205 vary greatly with PMSD upon emissions. In this study, we will evaluate these three
206 PMSD schemes and the impact on AOD, dust concentrations as well as its export
207 efficiency along the trans-Atlantic transport from Africa to the Amazon Basin.

208 **2.2 Observations**

209 The study uses observations from multiple datasets obtained from AERONET,
210 MODIS, as well as Cayenne site and the Amazon Tall Tower Observatory (ATTO) site
211 to constrain model results regarding the simulation of the dust export from Africa to
212 the Amazon Basin. Table 2 summarizes these observations, including the parameters,
213 the spatio-temporal coverage, and the corresponding application in the model. The
214 daily data of AOD (at wavelength of 675 nm) and particle volume size distribution
215 (PVSD) from AERONET level 2.0
216 (aeronet.gsfc.nasa.gov/new_web/download_all_v3_aod.html, last access on Jun. 22,
217 2021(Dubovik et al., 2002)) during the year of 2013 – 2017 is used in the study to
218 evaluate dust emissions and its PMSD over the source regions in Africa in the model.
219 The PVSD data provided by AERONET is a column-integrated aerosol volume size
220 distribution and with a size range of 0.05 – 15.0 μm . It is then converted to PMSD
221 using the same densities as in the model. Only sites with valid data accounting for
222 more than 30% of the total are considered in this study. In addition, to minimize the
223 influence of aerosols other than dust, only data dominated by dust (simulated dust
224 contribution to column-integrated aerosols mass concentrations > 95%) is used for the
225 comparison of PMSD. There are a few sites not far from the coast and could be
226 influenced by sea salt. With the above data screening, the sea salt contribution to total
227 aerosol mass is less than 0.5%. For the comparison of AOD, the criterion is less
228 stringent to have more data points available and uses data dominated by coarse
229 aerosols (the contribution of fine aerosol to total aerosol volume < 3%). This criterion
230 does not exclude sea salt and the contribution of sea salt to AOD could be up to 30%
231 at the Capo_Verde site (22.9° W,16.7° N) over the east of the Atlantic Ocean.
232 The study also uses observed PMSD over central Sahara during Fennec Campaign
233 (africanclimateoxford.net/projects/fennec/, last access: 22 June 2021) for the
234 comparison with AERONET and our model results. Aiming to investigate dust
235 microphysical and optical properties, 42 profiles of size distribution (0.1 – 300 μm in
236 diameter) over both the Sahara and the Atlantic Ocean, were sampled from in-situ
237 aircraft measurements during Fennec campaign. For more detailed description of the

238 aircraft measurements, readers are referred to Ryder et al. (2013a).
239 In addition to AERONET AOD data, level 3 daily AOD (at wavelength of 550 nm)
240 data from the moderate resolution imaging spectroradiometers (MODIS) installed on
241 Terra and Aqua platforms
242 (<https://ladsweb.modaps.eosdis.nasa.gov/archive/allData/61/>, last access: 22 June
243 2021) is applied in the study to evaluate the trans-Atlantic transport of dust plumes
244 from Africa toward Amazon Basin. For comparison, we degraded the original
245 horizontal resolution of MODIS data ($1^\circ \times 1^\circ$) to $2^\circ \times 2.5^\circ$, consistent with the model
246 outputs.
247 Finally, daily PM_{10} mass concentrations during wet season (from January to April) in
248 2014 measured at Cayenne, French Guiana (52.3097° W, 4.9489° N, located in the
249 northeast coast of the Amazon Basin, <https://doi.org/10.17604/vrsh-w974>, marked in
250 Figure 1) and long-term aerosol measurements at the Amazon Tall Tower
251 Observatory, Brazil (59.0056° W, 2.1459° S, located in central Amazon Basin,
252 also marked in Figure 1) are used in this study to further evaluate the model
253 performance regarding the influence of the LRT of African dust over the Amazon
254 Basin. The measurement at Cayenne site is carried out on a cooperative basis by
255 personnel of ATMO-Guyane, a non-profit organization. The PM_{10} samples are
256 measured by a Taper Element Oscillating Microbalance (TEOM, model 1400 series,
257 ThermoFisher Scientific) and then are returned to Miami for analysis (Prospero et al.,
258 2020). Readers are referred to Prospero et al. (2020) for detailed description of the site
259 and the data. The ATTO site was established in 2012 for the long-term monitoring of
260 climatic, biogeochemical, and atmospheric conditions in the Amazon rainforest.
261 Detailed description of the site and the measurements there could be found in Andreae
262 et al. (2015). In this study, we only use the particle number size distribution from an
263 Optical Particle Sizer (OPS, TSI model 3330; size range of 0.3 – 10 μm in diameter,
264 divided into 16 size bins) and a Scanning Mobility Particle Sizer (SMPS, TSI model
265 3080, St. Paul, MU, USA; size range of 10 – 430 nm in diameter, divided into 104
266 size bins) over the period from 2014 to 2016. The number size distribution is

267 converted to mass concentrations assuming spherical particles with a constant density
268 of 1.5 g cm^{-3} (Pöschl et al., 2010).

269

270 **3 Model evaluation**

271 Here we evaluate three different PMSD schemes regarding the model performance of
272 dust simulation through the comparison with observed mass size distribution of
273 column-integrated aerosol over Africa, AOD over both Africa and the Atlantic Ocean,
274 as well as PM_{10} and dust concentrations in the Amazon Basin. Figure 2 shows the
275 mass fractions of column-integrated aerosols retrieved from AERONET sites
276 compared with model results based on different PMSD schemes. The location of the
277 selected AERONET sites with valid data are marked in Figure 1 as purple symbols
278 (including asterisks and circles). The mean mass fractions for each bin from
279 AERONET data are 17%, 27%, 38%, 17%, respectively. The comparison indicates the
280 model results based on V12_C agrees better with the observations, with much smaller
281 mean absolute deviation (MAD) of 2.8, followed by 4.2 for V12 and 18 for V12_F. In
282 other words, the model results with other PMSD schemes (V12_F in particular)
283 greatly underestimate the mass fractions in the first bin and overestimate the mass
284 fractions in the last bin. During the Fennec campaign, the aircraft sampled two strong
285 Saharan dust outbreaks with AOD up to 1.1, which may be associated with strong
286 winds favoring the uplift of large particles.

287 Figure 3 shows the times series of daily AOD at wavelength of 675 nm during the
288 year of 2013 – 2017 from both AERONET and model results. The locations of the
289 selected AERONET sites with valid data over northern Africa are shown in Figure 1
290 as purple circles. The Capo_Verde site over the east of the Atlantic Ocean is also
291 included to show the model performance over the ocean in addition to the land.

292 Although different PSD schemes have little influence on the correlation between
293 AERONET and model results with most r around 0.6 – 0.7, the normalized mean bias
294 (NMB) has been significantly improved in V12_C, with a range of -12% – 11% (vs. -
295 33% – -11% and -42% – -19% for V12 and V12_F, respectively). The severe

296 underestimation in AOD from V12 and V12_F could be attributed to their relatively
297 higher dust fractions distributed in larger size bins with lower MEE.

298 In addition, we also compare the spatial distributions of simulated AOD over the
299 Atlantic Ocean with MODIS AOD (at 550 nm) averaged over 2013 – 2017 in Figure
300 4a-d. There is a clear decreasing trend in MODIS AOD along the trans-Atlantic
301 transport from Africa towards South America. Although all simulations show similar
302 spatial distributions with declining trends of AOD along the transport, the results from
303 V12_C are the most consistent with MODIS data with the highest r of 0.89 and the
304 smallest NMB of 6.5% among the three schemes (vs. r of 0.85 and 0.81 and NMB of -
305 13% and -19% for V12 and V12_F, respectively). Note that the model results based
306 on V12_C tends to overestimate MODIS AOD over Africa while no significant
307 systematic bias is found between V12_C and AERONET AOD. Wang et al. (2016)
308 sampled MODIS data at AERONET sites over Africa and found that MODIS retrieval
309 underestimate AERONET AOD at most sites with NMB of -12% – -36%, which
310 partly explain the large difference between model V12_C and MODIS AOD.

311 Assuming first-order removal of aerosol along the transport, we could derive the
312 removal rates of aerosols, estimated as the gradient of the logarithm of AOD
313 ($\log(\text{AOD})$) against the distance over the Atlantic Ocean along the transport path
314 (AOaTP, 20° – 50° W and 5° S – 25° N, Figure 4e). The decline rate of MODIS
315 $\log(\text{AOD})$ is $0.019 \pm 0.0025 \text{ degree}^{-1}$. A similar decline rate of $0.019 \pm 0.0029 \text{ degree}^{-1}$
316 is found for simulated $\log(\text{AOD})$ based on V12_C. In contrast, simulations with V12
317 and V12_F exhibit relatively steeper slopes of 0.021 ± 0.0040 and 0.021 ± 0.0041 ,
318 respectively, implying too much aerosol removal and thus lower export efficiency
319 along the transport. To specify the impact of different PMSD on the export efficiency
320 of dust aerosols towards the Amazon Basin, Figure 4f also shows simulated dust AOD
321 (DOD) along the transect from 20° to 50° W. The DOD from V12_C decreases from
322 0.15 ± 0.018 to 0.049 ± 0.088 along the transport, with a decreasing rate of $0.016 \pm$
323 $0.0014 \text{ degree}^{-1}$. In contrast, DOD decreases from 0.097 ± 0.012 to 0.028 ± 0.085 with
324 a slope of 0.018 ± 0.0016 for V12 and decreases from 0.080 ± 0.090 to 0.025 ± 0.084

325 with a slope of 0.017 ± 0.0014 for V12_F.

326 Lying in the trade wind belt, Cayenne has been taken as the gate of African dust.

327 Hence, the comparison between simulated and observed dust concentrations at

328 Cayenne site could evaluate model performance in reproducing the arrival of African

329 dust to the Amazon Basin. As shown in Figure 5a, the simulation from V12_C shows

330 excellent agreement between simulated dust and observed PM₁₀ concentration during

331 wet season, with r around 0.85 and NMB of -39%. The correlation from the other two

332 simulations is similar ($r = 0.86$), but the corresponding NMB is much larger (-57% for

333 V12 and -80% for V12_F). Based on the regression line between observed

334 concentrations of PM₁₀ and dust at the same site, Prospero et al. (2020) obtained a

335 regional background value of PM₁₀ ranging from 17 to 22 $\mu\text{g m}^{-3}$, largely attributed to

336 sea salt aerosol, and a value of 0.9 for the slope, suggesting PM₁₀ values above this

337 range as a proxy for advected dust. Consistent with their results, the regression line

338 between simulated dust and PM₁₀ from V12_C in this study shows a background

339 value of PM₁₀ around 23 $\mu\text{g m}^{-3}$, with a value of the slope around 1.0, and the dust

340 contribution to PM₁₀ is around $53\% \pm 20\%$. In contrast, the regression lines from V12

341 and V12_F are much steeper, with the slope of 1.4 and 2.1, respectively, and the dust

342 contributions are relatively smaller, 44% in V12 and 34% in V12_F.

343 We also compare simulated dust concentrations with observed coarse particles at

344 ATTO site in central Amazon in wet season during 2014 – 2016 in Figure 5b. The

345 correlation between observed and simulated data are similar for different PMSD

346 schemes with r of 0.63 – 0.65. But the bias of V12_C is negligible (NMB = -0.27%)

347 while both V12 and V12_F tend to underestimate the coarse aerosol concentrations

348 with NMB of -36% and -55%, respectively. The dust contribution to coarse aerosols

349 is above 80% in V12_C, but less than 70% in V12_F. This again implies relatively

350 higher export efficiency of African dust aerosols towards the Amazon Basin with

351 V12_C associated with their relatively higher dust fractions distributed in smaller size

352 bins.

353 Overall, compared with V12 and V12_F schemes, model results based on V12_C are

354 more consistent with the multiple observed data sets, including column-integrated
355 particle size distribution, AOD and surface coarse aerosol concentrations obtained
356 either over sources or downwind of the sources. Therefore, we use the model results
357 from V12_C (hereinafter referred to as model results unless noted otherwise) to
358 investigate the transatlantic transport of dust from Africa and its impact over the
359 Amazon Basin in the following sections.

360

361 **4 Results and discussion**

362 **4.1 Dust emissions**

363 Figure 1 shows the spatial distribution of simulated dust emissions and Table 3 lists
364 seasonal and annual dust emissions in northern Africa (17.5° W – 40° E, 10° N – 35°
365 N) for the period of 2013 – 2017. Simulated annual dust emission from northern
366 Africa is 0.73 ± 0.12 Pg yr⁻¹, contributing more than 70% of the global dust emission
367 (0.99 ± 0.20 Pg yr⁻¹). The result is in the range of $0.42 - 2.05$ Pg yr⁻¹ reported by Kim
368 et al. (2014), who evaluated five AeroCom II global models regarding the dust
369 simulation over similar regions.

370 There exists a strong seasonality in the dust emission from northern Africa, peaking in
371 spring and winter (up to 1.2 Pg yr⁻¹) and reaching the minimum in fall (around 0.33
372 Pg yr⁻¹) in general. Previous studies have also pointed out that dust emissions over
373 different African regions show distinct variations (Bakker et al., 2019; Shao et al.,
374 2010), attributed to differences in geographical properties (Knippertz et al., 2007),
375 vegetation cover (Mahowald et al., 2006; Kim et al., 2017), and meteorological
376 mechanisms on a local scale (Alizadeh-Choobari et al., 2014; Wang et al., 2017;
377 Roberts and Knippertz, 2012). Consequently, there exists substantial seasonal change
378 in dust source regions. For instance, during boreal winter, the Bodélé Depression in
379 northern Chad is found to be the most active triggered by the Harmattan winds, while
380 the northwestern African dust sources become less active in contrast with the
381 condition in boreal summer (Ben-Ami et al., 2012; Prospero et al., 2014). Therefore,
382 we further analyze the emission variability over five different source regions in

383 northern Africa (Figure 1 and Table S1). On an annual basis, the contribution to total
384 northern African dust emission is the largest from Region A (west Sahara, $36\% \pm$
385 4.0%), followed by Region D (central Sahel including the Bodélé Depression, $21\% \pm$
386 4.7%), Region B (central Sahara, $13\% \pm 2.6\%$), Region C (east Sahara, $12\% \pm 1.0\%$),
387 and Region E (west Sahel, $6.5\% \pm 0.64\%$). The emission fluxes, however, are the
388 most intensive in Region D, up to $11 \pm 2.1 \text{ g month}^{-1} \text{ m}^{-2}$ and are generally below 5 g
389 $\text{month}^{-1} \text{ m}^{-2}$ over the other regions.

390 Concerning the seasonality, higher dust emission tends to occur in boreal spring and
391 winter, with the largest emission flux of $19 \pm 4.7 \text{ g month}^{-1} \text{ m}^{-2}$ from Region D. As
392 shown in Figure 6 and S1, the emissions peak in boreal spring for Region A, B and C,
393 but in winter for Region D and E. There is also a secondary peak in summer
394 emissions for Region E. Correlation analysis between dust emissions and
395 meteorological variables suggests that the seasonality is mainly driven by high surface
396 wind speeds (with r of 0.79-0.96 and 0.68-0.97 for the 75th and 95th percentiles of 10-
397 m wind speeds, respectively). Apparent negative correlation is also found between
398 precipitation (soil moisture, Figure S1) and dust emission in Region D with r of -0.69
399 (-0.67).

400 Similar seasonality is also reported by Cowie et al. (2014), who suggested that the
401 strongest dust season in winter in central Sahel is driven by strong harmattan winds
402 and frequent Low level Jet breakdown, and the second peak in summer in west Sahel
403 could be explained by the summer monsoon combined with the Sahara Heat Low. The
404 study also suggested the dominance of strong wind frequency in the seasonal variation
405 of the emission frequencies. Fiedler et al. (2013) also found a maximum of emission
406 flux over the Bodélé Depression in winter and the highest emission flux in spring in
407 west Sahara. The study suggested that near-surface peak winds associated with
408 Nocturnal Low-Level Jets is a driver of mineral dust emissions. Negative correlation
409 between dust emissions and soil moisture has also been revealed by Yu et al. (2017)
410 and Pierre et al. (2012), as the decreased vegetation growth in response to dry soil
411 would result in enhanced dust emissions.

412 It is also worth noting that the interannual variation in dust emission is much larger
413 during the wet season ($0.96 \pm 0.25 \text{ Pg yr}^{-1}$, Table 3) than on an annual basis ($0.73 \pm$
414 0.12 Pg yr^{-1}). Moreover, while the annual emissions gradually decrease from 2013 to
415 2017, the emissions during the wet season peak in 2015. The obviously different
416 behavior between the annual emissions and emissions during the wet season suggests
417 that predictions of future impact of African dust emissions over the Amazon Basin in
418 response to climate change should focus on the wet season rather than the annual
419 average, as the former is more related to the export of African dust towards the
420 Amazon Basin.

421 **4.2 Transatlantic transport of African dust**

422 The amount of African dust reaching the Amazon Basin depends not only on the dust
423 emission fluxes, but also the transport path. Associated with the annual oscillation of
424 ITCZ, the outflow of African dust moves slightly southwest toward South America in
425 boreal winter and spring, and moves west towards the Caribbean in boreal summer and
426 fall (Moran-Zuloaga et al., 2018; Ben-Ami et al., 2012). Therefore, although higher
427 dust load over the coastal region of North Africa is found in summer ($> 500 \text{ mg m}^{-2}$),
428 dust reaching the Amazon Basin is less than 10 mg m^{-2} . In contrast, dust load over the
429 Amazon Basin could reach up to 50 mg m^{-2} in spring and winter.

430 In addition to the transport path, the changes in dust column burden along the
431 transport towards the Amazon Basin are also sensitive to its removal rate, namely the
432 lifetime against deposition over the Atlantic. Assuming first-order removal of dust
433 aerosols, we further derived seasonal e-folding lifetime (hereinafter referred to as
434 lifetime, τ) of simulated dust during 2013 – 2017, based on the logarithm of the dust
435 column burden against travel time over the AOaTP (Figure 7) using Equation 1:

$$436 \quad \tau = \frac{L}{v \times slope} \quad (1)$$

437 where L is the distance of 1-degree longitude averaged over $5^\circ \text{ S} - 25^\circ \text{ N}$ in unit of m
438 degree^{-1} ; v is the wind speed in unit of m s^{-1} ; and $slope$ is the gradient of the linear
439 trend line based on the logarithm of dust burden against the distance in degree
440 between 20° W and 50° W .

441 Estimated dust lifetime is the shortest ($1.4 \pm 0.098 \text{ d}$) in winter, followed by fall and

442 spring (1.9 ± 0.33 d and 2.3 ± 0.31 d, respectively), while the lifetime in summer is
443 the longest (4.2 ± 0.68 d). The interannual variability of the lifetime is small in winter
444 with relative standard deviation (RSD) of 7.0%, but relatively large in fall with RSD
445 of 17%. The short lifetime in winter is generally associated with high deposition flux
446 (including both dry and wet deposition). As shown in Figure 8, the largest dust
447 deposition flux (> 1000 ng m⁻² s⁻¹) is found over the source regions in northern Africa,
448 especially in spring and winter, and is mainly due to dry deposition (accounting for
449 more than 80%). As a result, 48% – 64% of total emission in northern Africa is
450 deposited within the source region (Table S2). The deposition flux over the AOaTP,
451 also shows strong seasonality, with a maximum of ~ 530 ng m⁻² s⁻¹ in winter and a
452 minimum of ~ 180 ng m⁻² s⁻¹ in fall, and is mainly driven by wet deposition
453 (accounting for 76% on average). The deposition over the AOaTP accounts for 20%
454 of total emission in northern Africa in winter, in contrast to 7.7% in spring, consistent
455 with the relatively shorter lifetime in winter discussed above.

456 The seasonality in the deposition fluxes and the consequent dust lifetime depends not
457 only on precipitation but also the vertical pathways of dust transport across the
458 Atlantic. Dust aerosols aloft at higher altitude reach further west and have relatively
459 longer lifetime. Significant differences in dust vertical distributions along the
460 transport pathways have been revealed from the CALIOP measurements, which show
461 that more dust is transported above 2km in summer while the dust layer is the
462 shallowest in winter (Liu et al., 2012).

463 **4.3 The influence of African dust over the Amazon Basin**

464 **4.3.1 Surface aerosol concentrations**

465 Figure 9 shows the time series of observed and simulated aerosol mass concentrations
466 at ATTO in January – June for the period of 2014 – 2016. Observed mean concentration
467 in wet season is 9.3 ± 7.6 $\mu\text{g m}^{-3}$, of which 83% is from coarse aerosol (7.7 $\mu\text{g m}^{-3}$),
468 while simulated concentration is 11 ± 6.7 $\mu\text{g m}^{-3}$, with dust contribution of 65% (7.2 $\mu\text{g m}^{-3}$).
469 The slight model bias could be to some extent explained by the difference in
470 background concentrations (1.9 and 5.1 $\mu\text{g m}^{-3}$ for the observation and model data,
471 respectively). Most of observed peaks are found in February – March of 2014 and 2016,

472 and in February – April of 2015. The high correlation (r of 0.52 – 0.71) between
473 observed coarse aerosols and simulated dust concentrations suggests that observed
474 strong variation in coarse aerosols is mainly driven by the influence of dust. Rizzolo et
475 al. (2017) conducted aerosol measurements at ATTO from 19 March to 24 April 2015.
476 The study showed the arrival of African dust between 3 and 6 April when the highest
477 concentrations of PM₁₀, soluble Fe (III) and Fe (II) were recorded at ATTO. The peak
478 value of 23 $\mu\text{g m}^{-3}$ for PM₁₀ was observed on 5 April. This dust event is well reproduced
479 in this study with the peak value of 28 $\mu\text{g m}^{-3}$ for PM₁₀ on the same day and the dust
480 contribution to PM₁₀ reaching above 70%. The co-occurrence of elevated sea salt
481 concentration (reaching 2.5 $\mu\text{g m}^{-3}$) during this event is also found in this study,
482 consistent with previous studies which show mixed transport of African dust and marine
483 aerosol to the basin (Wang et al., 2016; Ben-Ami et al., 2010; Rizzolo et al., 2017;
484 Adachi et al., 2020).

485 The dust peaks are generally associated with large dust emission and/or efficient
486 trans-Atlantic transport (e.g. relatively longer lifetime). For example, the relatively
487 higher dust concentrations in the wet season of 2015 (except for February) are
488 generally associated with higher emissions (1.2 – 1.5 Pg yr⁻¹) compared with the year
489 of 2014 and 2016 (0.68 – 1.0 Pg yr⁻¹, see Table S3). On the other hand, although
490 emissions in February 2016 (0.95 Pg yr⁻¹) is slightly lower than those in February
491 2014 (1.2 Pg yr⁻¹), the relatively longer lifetime (1.7 d vs. 1.5 d) may help explain the
492 high dust concentrations during that period. It should be noted that the lifetime
493 estimated here represents the export efficiency averaged over a relatively large
494 domain and a long-time scale (e.g. one month). Besides, the influence of African dust
495 on the ATTO site is also subject to the variations of transport paths and precipitation
496 fields.

497 Over the whole Amazon Basin, simulated mean surface dust concentrations in the wet
498 season of 2013 – 2017 are $5.7 \pm 1.3 \mu\text{g m}^{-3}$, with a maximum of $7.9 \mu\text{g m}^{-3}$ in 2015
499 driven mainly by the relatively high dust emission flux. The maxima of surface dust
500 concentrations are found in the northeast corner of rainforest (over $15 \mu\text{g m}^{-3}$) with a
501 clearly decreasing trend towards southwestern direction (Figure 10). The dust
502 contribution to surface aerosol concentrations averaged over the whole basin is $40\% \pm$

503 4.5%, again with the maximum of 48% found in 2015. The location with the largest
504 dust contributions (up to 70% in the north corner) slightly shifted inland compared to
505 the spatial distribution of dust concentration. This could be explained by relatively
506 higher influence of sea salt aerosols along the coast (around 30-50% near the coast of
507 South America). Although the emission fluxes of both sea salt and dust are largely
508 determined by surface winds, the interannual variability of dust concentrations is
509 larger than sea salt over the Amazon Basin (20% vs. 10%) as the former is also
510 sensitive to the export efficiency across the Atlantic Ocean as discussed above.
511 Figure 10c also shows the frequency of dust events over the Amazon Basin, estimated
512 as the number of days when daily surface dust concentrations reaching the threshold
513 of $9 \mu\text{g m}^{-3}$ (Moran-Zuloaga et al., 2018) divided by the total number of days in the
514 wet season of 2013 – 2017. Dust frequency averaged over the whole region is around
515 $18\% \pm 4.6\%$ and decreases from 50 – 60% at the northeast coast to $< 1\%$ in southern
516 inland. The frequency of dust events at ATTO site is around 32%, close to the median
517 of the range. The interannual variation of the frequency (represented by RSD),
518 however, has an opposite trend, gradually increasing from 10% at the northeast coast
519 to over 100% in southern inland (36% at ATTO). During dust events, the dust mass
520 concentration at ATTO reaches $16 \pm 2.9 \mu\text{g m}^{-3}$ (three times as high as that over the
521 whole wet season), accounting for around $75\% \pm 5.3\%$ of total aerosol (Figure 10d).
522 Similarly, under the influence of the long-range transport of Saharan dust plumes,
523 Moran-Zuloaga et al. (2018) observed mass concentrations $14 \pm 12 \mu\text{g m}^{-3}$ for coarse
524 aerosol at the same site, accounting for 93% of total observed aerosol.

525

526 **4.3.2 AOD**

527 The contribution of DOD to AOD at 550 nm over most areas of the Amazon Basin
528 (Figure 11) is in the range of 10 – 50% ($23\% \pm 4.4\%$ on average) during the wet
529 season of 2013 – 2017, with maxima in the northern Amazon Basin. The dust
530 contribution to total AOD is relatively smaller than that to surface aerosol
531 concentrations, mainly because of the relatively lower MEE of dust aerosols

532 compared to other aerosols. There also exists large difference in DOD between the
533 whole wet season and dust events: 0.021 ± 0.0055 vs. 0.055 ± 0.0076 averaged over
534 the Amazon Basin. A maximum of 0.31 on a daily basis is found on 1 Mar 2016 at the
535 northeast corner (55° W, 4° N) of the Amazon Basin during the study period. During
536 dust events, dust aerosols dominate AOD (40% – 60%) over most regions of the
537 Amazon Basin. At ATTO site, DOD is 0.034 ± 0.0088 and 0.063 ± 0.0087 , accounting
538 for 37% and 53% of AOD over the whole wet season and dust events, respectively.
539 The largest dust contribution (up to 81%) with DOD of 0.18 at ATTO site is found on
540 24 Jan 2015. Consistent with our results, previous studies by Baars et al. (2011) and
541 Baars et al. (2012) reported DOD (532 nm) of up to 0.18 and AOD of ~ 0.14 when
542 affected by strong influence of Saharan dust at a similar Amazon site ($60^\circ 2.3'$ W, 2°
543 $35.9'$ S).

544

545 **4.3.3 Dust deposition and related nutrient input**

546 The spatial distribution of dust deposition over the Amazon Basin is also shown in
547 Figure 8. The mean dust deposition flux in wet season is 2.0 ± 0.35 $\text{g m}^{-2} \text{yr}^{-1}$, much
548 higher than in dry seasons (August to November, 0.35 ± 0.16 $\text{g m}^{-2} \text{yr}^{-1}$). The
549 maximum (2.6 $\text{g m}^{-2} \text{yr}^{-1}$) is found in the year 2015 due to relatively large dust
550 emission and efficient trans-Atlantic transport. With emission of 0.96 ± 0.25 Pg yr^{-1} in
551 wet season (0.73 ± 0.12 Pg yr^{-1} on annual average), only 1.9% (1.4%) of African dust
552 is deposited into the Amazon Basin (dominated by wet deposition) while relatively
553 large part is deposited over the AOaTP (13% in the wet season and 14% on annual
554 average) and northern Africa (49% in the wet season).

555 Assuming mass fractions of 4.4%, 0.082%, and 1.8% for iron, phosphorus, and
556 magnesium respectively in the African dust (Bristow et al., 2010; Chiemeka et al.,
557 2007), we derive deposition fluxes of 88 ± 15 $\text{mg m}^{-2} \text{yr}^{-1}$, 1.6 ± 0.29 $\text{mg m}^{-2} \text{yr}^{-1}$ and
558 36 ± 6.3 $\text{mg m}^{-2} \text{yr}^{-1}$ for iron, phosphorus and magnesium respectively into the
559 Amazon rainforest during the wet season and 52 ± 8.7 , 0.97 ± 0.16 and 21 ± 3.6 mg
560 $\text{m}^{-2} \text{yr}^{-1}$ on annual average (Figure 12). It should be noted that there exists large spatial

561 variation of nutrient input into the Amazon Basin associated with the patterns of dust
562 burden and dust deposition flux. The deposition flux decreases from over 70 mg m^{-2}
563 yr^{-1} at northeast coast to less than $7 \text{ mg m}^{-2} \text{ yr}^{-1}$ in inland for magnesium and
564 decreases from $> 9 \text{ mg m}^{-2} \text{ yr}^{-1}$ at northeast coast to less than $1 \text{ mg m}^{-2} \text{ yr}^{-1}$ in
565 southwestern Basin for phosphorus during the wet season. Similarly, the deposition
566 flux of iron during the wet season decreases from over $500 \text{ mg m}^{-2} \text{ yr}^{-1}$ at northeast
567 coast to less than $15 \text{ mg m}^{-2} \text{ yr}^{-1}$ in the southwest and is above $50 \text{ mg m}^{-2} \text{ yr}^{-1}$ in most
568 of the Amazon Basin. It seems that the nutrient input from Africa dust may play a
569 significant role in the northeastern part of the Amazon Basin, not in the southwest.
570 Table 4 summarized the estimates of dust and associated phosphorus deposition into
571 the Amazon Basin from previous studies. The estimated fluxes of dust and associated
572 phosphorus deposition are in the range of $0.81 - 19 \text{ g m}^{-2} \text{ yr}^{-1}$ and $0.48 - 16 \text{ mg m}^{-2}$
573 yr^{-1} . The large range is mainly driven by the high values ($19 \text{ g m}^{-2} \text{ yr}^{-1}$ and 16 mg m^{-2}
574 yr^{-1} for dust and associated phosphorus, respectively) from the study of Swap et al.
575 (1992). Based on observations during storm events and dust climatology, the study
576 estimated dust importation into the northeastern basin, which is most subject to the
577 intrusion of African dust. Besides the discrepancy in defined regions, the wide range
578 could also be partly explained by the application of different methods and associated
579 intrinsic uncertainties as mentioned in the Introduction. For instance, the estimates
580 from Swap et al. (1992) are mainly based on 1-month field measurements at three
581 sites located in the northeastern basin. Assumption about air exchange rate across the
582 coast to the basin, duration of dust storms as well as dust concentrations contained in
583 the dust plumes had to been made to extrapolate the dust deposition into the Amazon
584 Basin. Similarly, bias could also arise from insufficient observations available to
585 constrain models or satellite retrievals. Additional uncertainty may also stem from the
586 assumption about the P mass fraction, ranging from 0.07% to 0.108%. Our results are
587 similar to the finding of Prospero et al. (2020), which has also been constrained by the
588 observation at Cayenne.
589 According to Salati and Vose (1984), the total amount of phosphorous and magnesium

590 is 21.6 g m^{-2} and 29.8 g m^{-2} , respectively, in the ecosystem of the Amazon Basin (14.7
591 and 2.3 g m^{-2} respectively in the soil). On the other hand, Vitousek and Sanford
592 (1986) reported a loss of $0.8 - 4 \text{ mg m}^{-2} \text{ yr}^{-1}$ for phosphorus and $810 \text{ mg m}^{-2} \text{ yr}^{-1}$ for
593 magnesium in Brazilian ecosystem to surface waters. Estimated nutrient input from
594 African dust in our study accounts for 0.011% and 1.6% of total phosphorous and
595 magnesium in the soil over the Amazon Basin during the wet season (0.0066% and
596 0.91% on annual average), and could almost compensate the hydrologic losses of
597 phosphorous in Brazilian forest ecosystem. Similarly, Abouchami et al. (2013)
598 pointed out that most of the Amazonian rainforest is a system with an internal
599 recycling of nutrients. But the extra influx of nutrients from African dust might
600 account for a significant portion of the net outflux, i.e. dissolved discharge of nutrients
601 into rivers. Keep in mind that the estimates of nutrients influx are subject to the
602 uncertainties in the estimates of dust flux as well as the mass fractions of nutrients
603 contained in the dust. In addition, marine aerosols and biomassburning aerosols
604 mixed with the LRT of African dust may also play a role for certain essential nutrients
605 (Prospero et al., 2020; Abouchami et al., 2013). More observations including the mass
606 fraction of nutrient in dust aerosols and the deposition fluxes of those elements in the
607 Amazon Basin are necessarily required in the future work to better evaluate the
608 nutrient input associated with the African dust intrusion.

609

610 **5 Conclusion**

611 In this study, we use the GEOS-Chem model with optimized particle mass size
612 distribution (PMSD) of dust aerosols to investigate the influence of the export of
613 African dust towards the Amazon Basin during 2013 – 2017. The model performance
614 is constrained by multiple datasets obtained from AERONET, MODIS, as well as
615 Cayenne and ATTO sites in the Amazon Basin. The optimized PMSD in this study
616 well captures observed AOD regarding both the mean value as well as the decline rate
617 of the logarithm of AOD over the Atlantic Ocean along the transport path (AOaTP),
618 while the other two PMSD schemes tend to overestimate the decline rate by 11% and

619 underestimate the mean value by up to ~40%.

620 Simulated dust emission from northern Africa is $0.73 \pm 0.12 \text{ Pg yr}^{-1}$, accounting for
621 more than 70% of global dust emission. There exists a strong seasonality in dust
622 emission with peaks in spring or winter, which varies with source regions. The
623 correlation analysis suggests high surface wind speeds and low soil moisture as a
624 major driver for dust emissions. In addition to the transport path associated with the
625 oscillation of ITCZ, the export efficiency of African dust towards the Amazon basin is
626 sensitive to the removal of dust aerosol along the trans-Atlantic transport, which
627 depends on both assumed PMSD of dust aerosols in the model and meteorological
628 fields (i.e. precipitation and vertical transport path). The study further estimates the e-
629 folding lifetime of dust aerosols along the trans-Atlantic transport based on the
630 logarithm of the dust column burden against travel time over the AOaTP. The shortest
631 lifetime (1.4 d) is found for winter associated with high deposition flux, while the
632 highest dust burden over the AOaTP is found in summer mainly associated with its
633 longer lifetime (4.2 d).

634 Simulated surface dust concentration averaged over the whole Amazon Basin is $5.7 \pm$
635 $1.3 \mu\text{g m}^{-3}$ during the wet season of 2013 – 2017, contributing $40\% \pm 4.5\%$ to total
636 surface aerosols. Observed dust peaks at the ATTO site are generally associated with
637 large dust emission and/or efficient trans-Atlantic transport. The frequency of dust
638 events is $18\% \pm 4.6\%$ averaged over the Amazon Basin and up to 50% – 60% at the
639 northeast coast. During the dust events, DOD is around 0.055 ± 0.0076 and dominate
640 total AOD over most of the Amazon Basin. Associated with the deposition of African
641 dust, the study estimated annual inputs of 52 ± 8.7 , 0.97 ± 0.16 and $21 \pm 3.6 \text{ mg m}^{-2}$
642 yr^{-1} for iron, phosphorus and magnesium into the Amazon rainforest, which may well
643 compensate the hydrologic losses of nutrients in the forest ecosystem.

1069

1070 **Table 1.** Mass fractions (%) of dust emitted in each bin for different particle mass size
 1071 distribution (PMSD) schemes tested in GEOS-Chem.

Scheme	bin 1				bin 2	bin 3	bin 4
	sub-bin 1	sub-bin 2	sub-bin 3	sub-bin 4			
	(0.1 – 0.18) ^a (3.1) ^b	(0.18 – 0.3) ^a (4.3) ^b	(0.3 – 0.6) ^a (2.7) ^b	(0.6 – 1.0) ^a (0.96) ^b			
V12	0.7	3.32	24.87	71.11	19.2	34.9	38.2
V12_C	6	12	24	58.00	25.3	32.2	30.2
V12_F	3.9	8.06	43	45.04	11.9	15.6	67

1072 ^a size range in radius (μm) for each bin

1073 ^b mass extinction efficiency (MEE) at wavelength of 550 nm in unit of $\text{m}^2 \text{g}^{-1}$ for dust particles in
 1074 each bin in the GEOS-Chem mod

1075

1076 **Table 2.** Summary of the observations used in this study, including the parameters,
 1077 the spatio-temporal coverage, and the corresponding application in the model.

Datasets	Parameters	Locations	Periods (resolution)	Application
AERONET	AOD	northern Africa, the Atlantic Ocean	2013 – 2017 (daily)	Model AOD evaluation over northern Africa and the Atlantic Ocean
	PVSD ^a	northern Africa	2013 – 2017 (daily)	Model dust PMSD evaluation
Fennec Campaign	PMSD ^b	Over Mali and Algeria, Africa	17 – 28 June, 2011	Model dust PMSD evaluation
MODIS	AOD	northern Africa and the Atlantic Ocean	2013 – 2017 (daily)	Model AOD evaluation over northern Africa and the Atlantic Ocean
Cayenne	PM ₁₀	52.3097° W, 4.9489° N (France)	January – April, 2014 (daily)	Model dust mass concentration evaluation at the coast of South America
ATTO	PNSD ^c	59.0056° W, 2.1459° S (Brazil)	January – April, 2014 – 2016 (5 min)	Model dust mass concentration evaluation at the central Amazon Basin

1078 ^a particle volume size distribution; ^b particle mass size distribution; ^c particle number size
 1079 distribution

1080 **Table 3.** Annual and seasonal dust emissions (Pg yr^{-1}) in northern Africa ($17.5^\circ \text{W} -$
 1081 $40^\circ \text{E}, 10^\circ \text{N} - 35^\circ \text{N}$)^a.

Year	Spring	Summer	Fall	Winter	Annual (Wet season)

Figure 1. Simulated annual dust emissions in GEOS-Chem, averaged from 2013 to 2017. The location of AERONET sites used in Figure 2 are marked as purple symbols, of which circles represent the sites used in Figure 3. The region of the Amazon Basin is defined by purple lines. The location of Cayenne site in the northeast coast of South America and ATTO site in the central Amazon Basin are marked as green and red diamonds, respectively. The red rectangle illustrates the area of northern Africa (17.5° W – 40° E, 10° N – 35° N) and the orange rectangles shows the areas of five major source regions described in the text (A: 15° W – 10° E, 21° N – 35° N; B: 10° E – 25° E, 25° N – 35° N; C: 25° E – 35° E, 15° N – 32° N; D: 12.5° E – 23° E, 13° N – 21° N; E: 17° W – 5° W, 15° N – 21° N).

1114

1115

1116 **Figure 2.** Boxplots of the mass fractions of column-integrated aerosols in the four size bins (in
1117 radius) retrieved from AERONET sites over Africa compared with model results based on different
1118 PMSD schemes. The triangles represent the mean values.

1119

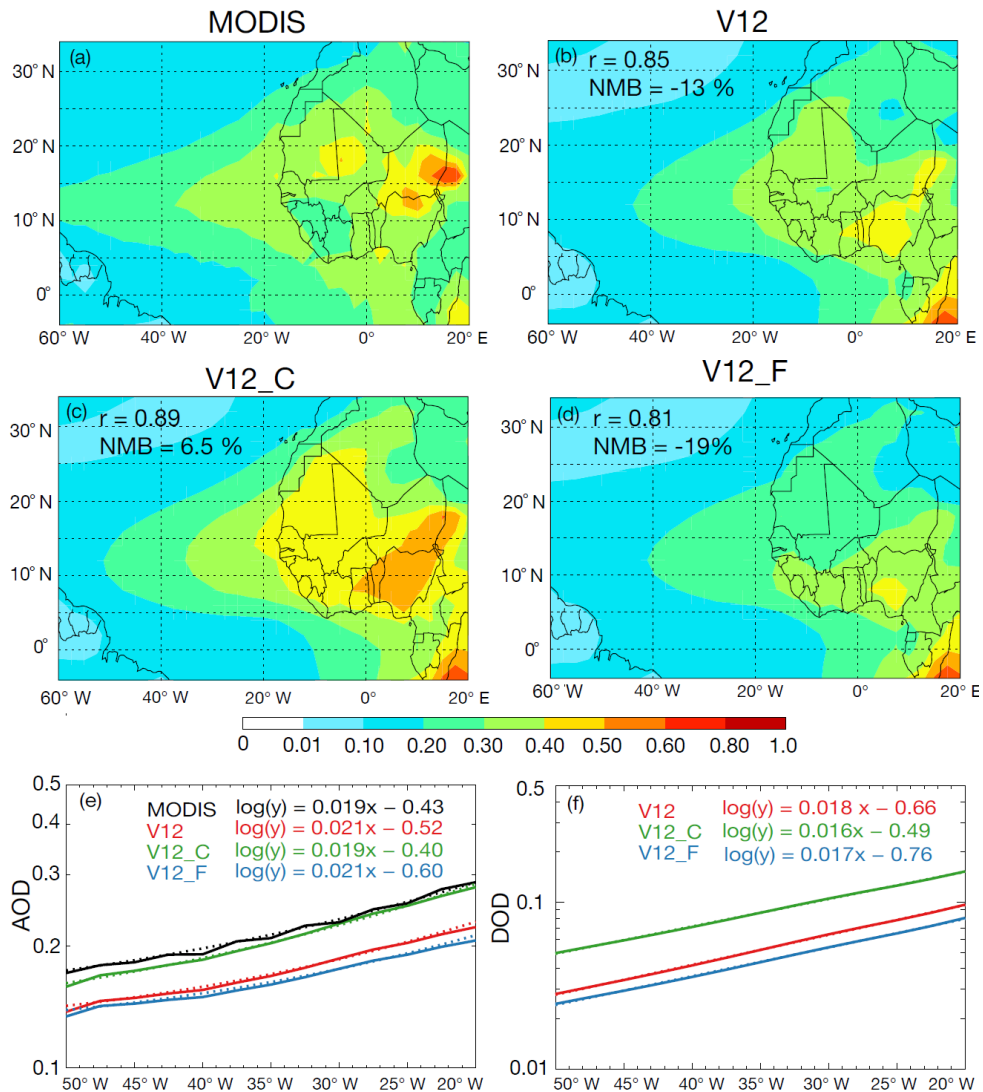

1120

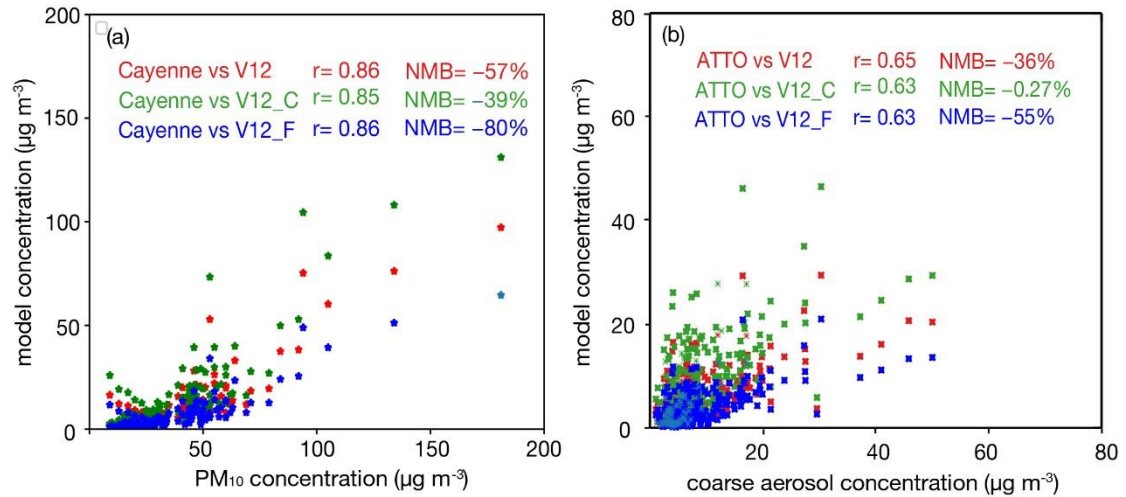

1121 **Figure 3.** Time series of AERONET (black lines) and simulated daily AOD (at wavelength of 675

1122 nm) during 2013 – 2017. Normalized mean bias (NMB) and correlation (r) statistics between the

1123 AERONET and simulated data are shown as inset.
 1124
 1125

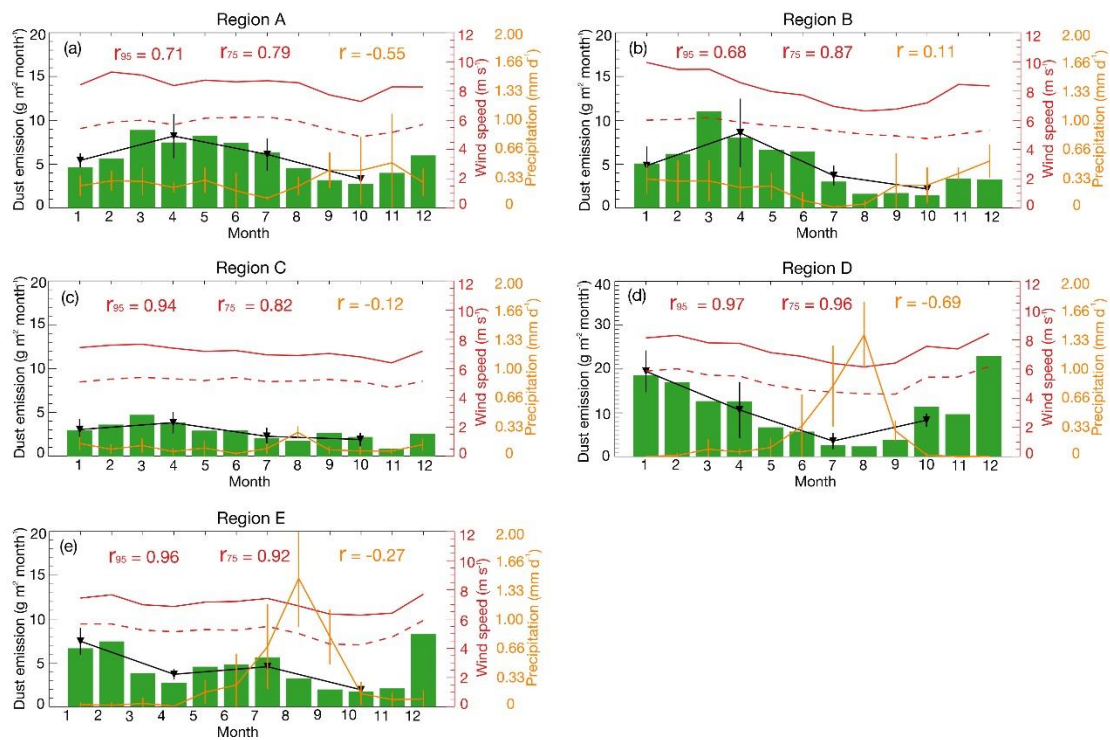

1126
 1127 **Figure 4.** (a) – (d) Spatial distributions of observed and simulated AOD (at 550 nm) over the region
 1128 of 60° W – 20° E and 10° N – 35° N averaged over 2013 – 2017. Normalized mean bias (NMB) and
 1129 correlation coefficient (r) between the simulations and MODIS AOD are shown as inset. (e) MODIS
 1130 (black) and simulated (color) AOD and (f) simulated dust optical depth (DOD) at 550 nm along the
 1131 transect from 20° to 50° W, averaged over 5° S – 25° N for the period 2013 – 2017. The solid lines
 1132 represent averaged data and the dashed lines are the logarithmic trend lines.
 1133

1134

1135 **Figure 5.** Scatter plots of (a) observed PM_{10} and simulated dust concentrations at Cayenne site
 1136 during wet season of 2014 and (b) observed coarse aerosol (PM_{1-10}) and simulated dust
 1137 concentrations at ATTO site during wet season of 2014-2016. Normalized mean bias (NMB) and
 1138 correlation (r) statistics between the observation and simulation are shown as inset.
 1139

1140

1141 **Figure 6.** Monthly dust emission fluxes together with the 95th percentile hourly 10-m wind speeds
 1142 (red solid lines), the 75th percentile hourly 10-m wind speeds (red dotted lines) and precipitation
 1143 (yellow lines) over the five major source regions averaged from 2013 to 2017. Seasonal emission
 1144 fluxes of dust are also shown as black lines. The correlation coefficients (r) between the dust
 1145 emission fluxes and different meteorological variables are also shown in each panel.

1146

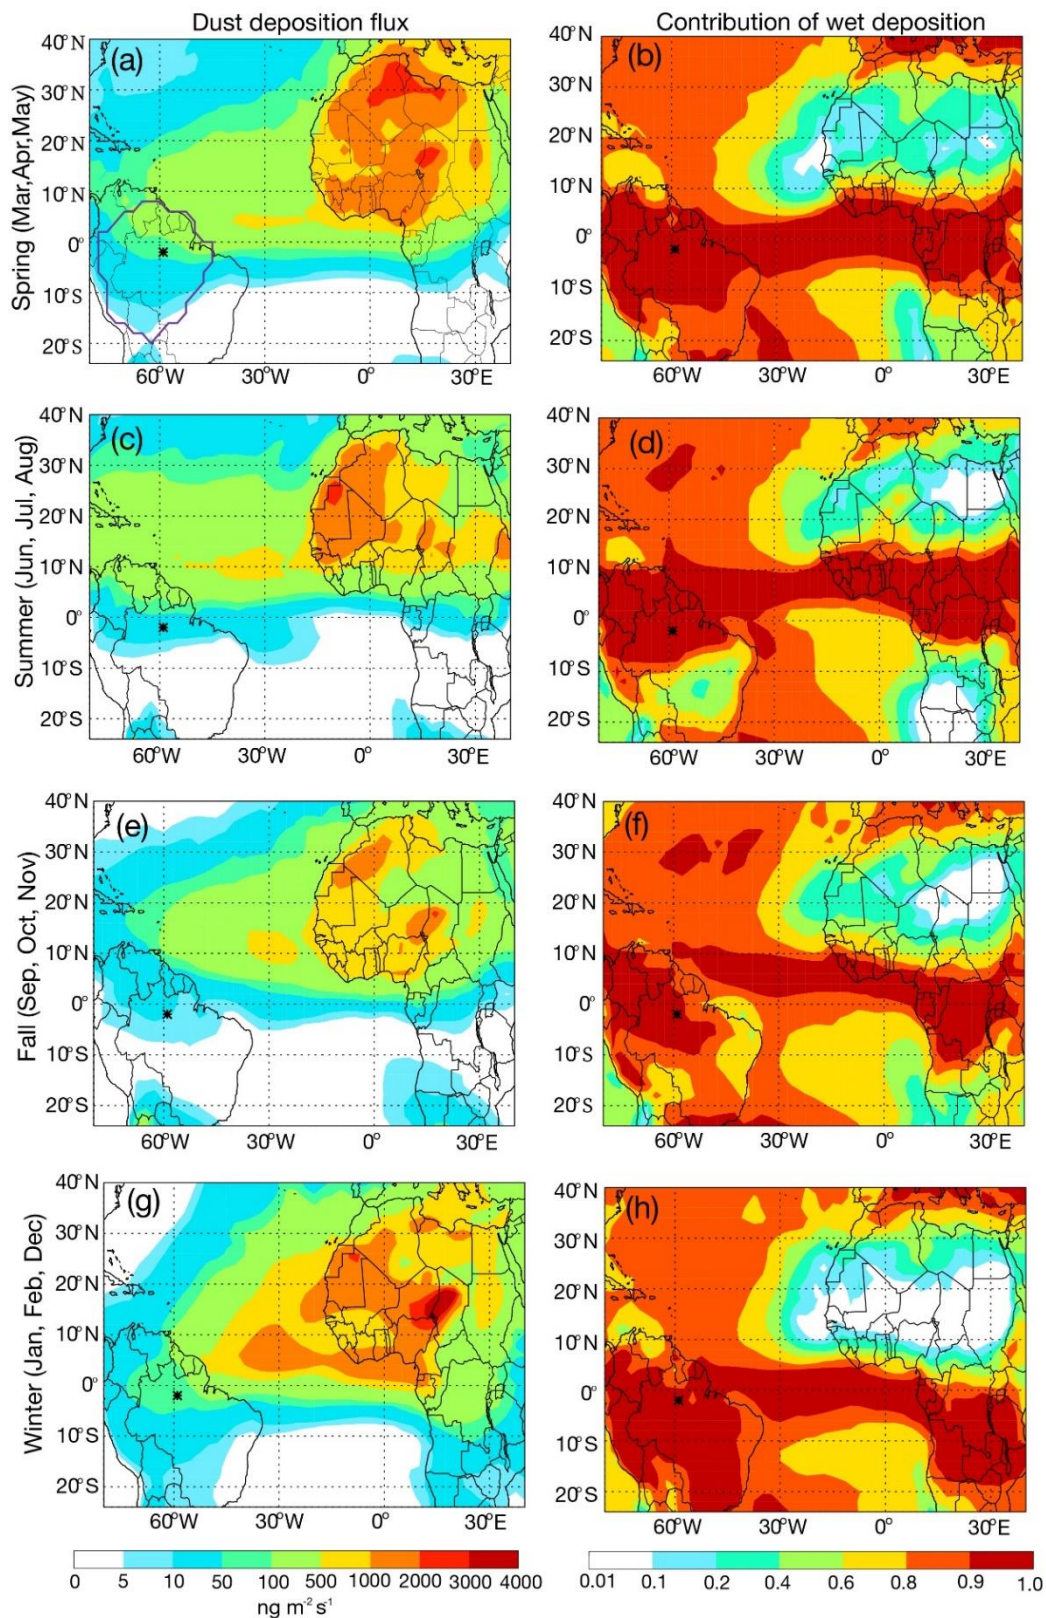

1147

1148

1149 **Figure 7.** Seasonal e-folding lifetime derived from the logarithm of simulated dust column burden
1150 against travel time along the transect from 20° W to 50° W averaged over 5° S – 25° N during the
1151 period of 2013 – 2017. The triangles represent the mean values, and the bottom and top sides of the
1152 boxes represent the minimums and maximums.
