37 **Abstract**

38

39 This study examines carbohydrates, amino acids, and lipids as important contributors to  
40 organic carbon (OC) in the tropical Atlantic Ocean at the Cape Verde Atmospheric Observatory  
41 (CVAO). The above compounds were measured in both surface seawater and in ambient  
42 submicron aerosol particles to investigate their sea-to-air transfer, including their enrichment  
43 in the sea surface microlayer (SML), potential atmospheric in situ formation or degradation,  
44 and their oceanic contribution to the ambient marine aerosol particles.

45 In bulk seawater and the SML, similar distributions among species were found for the lipids  
46 and carbohydrates with moderate SML enrichments (enrichment factor  $EF_{SML} = 1.3 \pm 0.2$  and  
47  $1.1 \pm 0.5$  respectively). In contrast, the amino acids exhibited a higher enrichment in the SML  
48 with an average ~~EF<sub>SML</sub>~~ of  ~~$2.3 \pm 0.4$~~   ~~$2.4 \pm 0.3$~~  although ~~they are being~~ less surface-active than  
49 lipids. The same compounds studied in the seawater were found on the ambient submicron  
50 aerosol particles whereas the lipids were more pronounced enriched ( $EF_{aer.} = 1.6 \times 10^5$ )  
51 compared to the amino acids and carbohydrates ( $EF_{aer.} = 1.5 \times 10^3$  and  $1.3 \times 10^3$  respectively),  
52 likely due to their high surface activity and/or the lipophilic character. Detailed molecular  
53 analysis of the seawater and aerosol particles revealed changes in the relative ~~composition~~  
54 ~~abundance~~ of the ~~single-individual~~ organic compounds. They were most pronounced for the  
55 amino acids and are likely related to an in situ atmospheric processing by biotic and/or abiotic  
56 reactions.

57 On average 49% of the OC on the aerosol particles ( $\triangleq 97 \text{ ng m}^{-3}$ ) could be attributed to the  
58 specific components or component groups investigated in this study. The majority (43%) was  
59 composed of lipids. Carbohydrates and amino acids made up less than 1% of the OC. This  
60 shows that carbohydrates, at least ~~when~~ resolved via molecular measurements of single  
61 sugars, do not comprise a very large fraction of OC on marine aerosol particles, in contrast to  
62 other studies. However, carbohydrate-like compounds are also present in the high lipid  
63 fraction (e.g., as glycolipids), but their chemical composition could not be revealed by the  
64 measurements performed here.

65 Previously determined OC components at the CVAO, ~~in detail~~ ~~specifically~~ amines, oxalic acid,  
66 and carbonyls, comprised an OC fraction of around 6%.

67 Since the identified compounds constituted about 50% of the OC and belong to the rather  
68 short-lived biogenic material probably originating from the surface ocean, a pronounced  
69 coupling between ocean and atmosphere was indicated for this oligotrophic region. The  
70 remaining, non-identified OC fraction might in part contain recalcitrant OC, however, this  
71 fraction does not constitute the vast majority of OC in the ~~here investigated~~ aerosol particles  
72 ~~here investigated~~.

80

## 1 Introduction

81 Marine aerosol particles, their composition, sources and connection to the upper ocean are  
82 not yet fully understood, however important ~~to assign, first of all, marine particle composition~~  
83 ~~to the most important contribution of primary sources and involved processes. Marine~~  
84 ~~particle composition as they then~~ impacts the carbon cycle and, radiative properties of aerosol  
85 particles, ~~and the function of aerosol particles as cloud condensation nuclei (CCN) and ice-~~  
86 ~~nucleating particles (INP), i.e. marine aerosol-cloud interaction~~ (Abbatt et al., 2019; Brooks and  
87 Thornton, 2018; Burrows et al., 2013; Gantt and Meskhidze, 2013; Pagnone et al., 2019; Patel  
88 and Rastogi, 2020). Furthermore, the function of (marine) aerosol particles as cloud  
89 condensation nuclei (CCN) and ice-nucleating particles (INP), i.e. marine aerosol-cloud  
90 interaction is still elusive. Important information about marine CCN is still missing (e.g.  
91 Bertram et al., 2018). Ocean-derived INPs have been suggested to play a dominant role in  
92 determining INP concentrations in near-surface air over remote areas such as the Southern  
93 Ocean, but their source strength in other oceanic regions and knowledge of which  
94 physicochemical properties determine INP efficiency remain largely unknown (Burrows et al.,  
95 2013; McCluskey et al., 2018a; McCluskey et al., 2018b). Marine aerosol particles, notably in  
96 the sub-micrometer range, have been shown to contain a large part of organic carbon (OC) in  
97 field experiments as well as in laboratory studies, where nascent aerosol particles are  
98 generated by artificial bubble-bursting mechanisms (Facchini et al., 2008; Keene et al.,  
99 2007; O'Dowd et al., 2004). Notably, the laboratory experiments, where sources other than  
100 the ocean (such as long-range transport) can be excluded, suggest that a certain part of the  
101 OC on the aerosol particles is transferred directly from the ocean via bubble bursting (Facchini  
102 et al., 2008; Keene et al., 2007). The mechanisms of the OC enrichment finally observed in  
103 aerosol particles are not yet fully understood but are likely due to complex interaction at the  
104 ocean surface when air bubbles rise and break. Air bubbles collect (organic) matter at their  
105 surface (the gas/water interface) when they ascend through the water column and when  
106 bursting, they produce film and jet droplets that transfer the OC to the atmosphere and form  
107 aerosol particles. At the ocean surface, the air bubbles enter the uppermost layer and the  
108 direct interface between the ocean and the atmosphere called the sea surface microlayer  
109 (SML) (Engel et al., 2017). The SML is described as a gel-like matrix that accumulates various  
110 organic and inorganic material (Cunliffe et al., 2013). The influence of the SML on the bubble  
111 bursting and the emission of OC into the atmosphere is difficult to determine and still  
112 controversial (Engel et al., 2017).

113 Based on the OC to sodium ratios in the ocean and the atmosphere, the OC in marine  
114 aerosol particles has shown to be strongly enriched compared to seawater concentrations. OC  
115 aerosol enrichment factors ( $EF_{aer.}$ ) of the order of  $10^2$  in supermicron aerosol particles and of  
116 the orders of  $10^3$  to  $10^5$  in submicron aerosol particles have been reported (Quinn et al., 2015  
117 and references therein). However, individual chemical groups, such as amino acids, can be  
118 even more enriched and  $EF_{aer.}$  as high as  $10^7$  for these particular compounds have been

119 measured in submicron particles resulting from bubble bursting experiments within a tank  
120 study (Triesch et al., 2021c). The OC transfer from the ocean to the atmosphere is likely highly  
121 chemo-selective and a hydrophobic nature as well as surface-active properties of organic  
122 compounds probably favour their transfer from the sea to the air (Rastelli et al., 2017;Schmitt-  
123 Kopplin et al., 2012).

124 An important ~~aspect component to~~for understanding the OC on ~~the~~ marine aerosol  
125 particles is the connection to oceanic bio-productivity. Several studies suggested that the  
126 marine aerosol composition is directly coupled to the productivity in the ocean, showing that  
127 at elevated chlorophyll-a (chl-a) concentrations in the seawater the OC on the aerosol particles  
128 is significantly higher when compared to the low oceanic productivity (O'Dowd et al.,  
129 2004;Facchini et al., 2008). A coupling between oceanic bio-productivity and aerosol  
130 composition is probably not straightforward. Wang et al., (2015) showed that two successive  
131 phytoplankton blooms in the tank seawater resulted in sea spray aerosols (SSA) with vastly  
132 different compositions and properties. Other studies, however, propose that the OC transfer  
133 from the ocean to aerosol particles is non-correlated to oceanic bio-productivity. Quinn et al.,  
134 (2014) suggested that the high reservoir of dissolved organic carbon (DOC) in the ocean is  
135 responsible for the organic enrichment in freshly emitted sea spray aerosol, thus dominating  
136 over any influence of recent local biological activity based on chlorophyll concentrations.  
137 Following this, Kieber et al., (2016) proposed that the major component in submicron sea-  
138 spray particles is of recalcitrant nature with a stability of months to millennia. They suggested  
139 that this persistent form of OC can very efficiently be transferred to the atmosphere via bubble  
140 bursting. Although they did not perform a detailed chemical analysis, they concluded that the  
141 recalcitrant organic matter exhibits surface-active properties. Applying natural abundance  
142 radiocarbon (<sup>14</sup>C) measurements it was recently suggested that 19 to 40% of the OC associated  
143 with freshly produced marine aerosol particles was refractory dissolved organic carbon (rDOC)  
144 (Beaupre et al., 2019).

145 In addition to the direct, or primary transfer of organic compounds from the ocean to  
146 the atmosphere, atmospheric processing changes the composition. Once released from the  
147 ocean to the atmosphere, organic matter can be acidified within seconds due to a pH change  
148 in the atmospheric particles or undergo fast photochemical oxidation (Kieber et al., 2016).  
149 Moreover, biogenic in situ formation and degradation can change the OC composition in  
150 marine aerosol particles and marine cloud water (Bianco et al., 2019;Malfatti et al.,  
151 2019;Matulova et al., 2014). Ervens and Amato (2020) provided a framework for estimating  
152 the production of secondary biological aerosol mass in clouds through microbial cell growth  
153 and multiplication. This pathway could be a significant source of biological aerosol material  
154 (Ervens and Amato, 2020;Khaled et al., 2021;Zhang et al., 2021). In other recent studies, the  
155 in situ formation of amino acids by biotic and abiotic processes in cloud water was measured  
156 and modelled (Jaber et al., 2021) and gel-like, organic particles, originally present in the ocean,  
157 were suggested to form in situ in the marine atmosphere via biotic and/or abiotic pathways  
158 (Haddrell and Thomas, 2017;Klein et al., 2016;van Pinxteren et al., 2022). Nevertheless,  
159 despite ~~a few~~some studies, the atmospheric in situ transformation of marine organic  
160 compounds and its significance has not yet been extensively studied ~~so far~~.

161 To understand the transfer processes of OC from the ocean to the aerosol particles,  
162 potential atmospheric OC in situ formation as well as the coupling of the OC on the aerosol  
163 particles to processes in the ocean, it is crucial to unravel the chemical composition of the  
164 aerosol OC content. In the present study, we investigated samples from the tropical Atlantic  
165 Ocean at the CVAO. The focus of this study was on the analysis of amino acids and  
166 carbohydrates, as well as of lipid components, as these OC groups are reported as the major  
167 marine organic matter groups in the seawater and therefore likely transferred to the aerosol  
168 particles via bubble bursting (Burrows et al., 2014). We investigated these compounds on  
169 marine aerosol particles and in the ocean SML and bulk water. Specifically, we followed the  
170 concentrations and speciation of OC from the sea to the atmospheric particles, which helps to  
171 evaluate the enrichment factors of the various targeted compounds between the  
172 compartments. The results will help to gain a better understanding of the chemical  
173 composition of marine aerosol particles in this tropical location, its transfer from the ocean  
174 and in situ formation, and finally, help to elucidate the coupling of marine aerosol particles to  
175 the surface ocean in an oligotrophic region.

176

## 177 2. Material and methods

### 178 2.1 Aerosol and seawater sampling during the campaign

179

180 A field campaign (MarParCloud) was carried out at the Cape Verde Atmospheric Observatory  
181 (CVAO, 16°51'49'N, 24°52'02'E) in autumn 2017 (13.09.2017 – 13.10.2017) and the sampling  
182 sites are illustrated and explained in detail in van Pinxteren et al., (2020). The CVAO is a remote  
183 marine station in the tropical Atlantic Ocean located on the northeast coast of Sao Vicente  
184 island and described in Carpenter et al., (2010) and Fomba et al., (2014). The ocean around  
185 the Cape Verde Islands has the lowest surface chlorophyll in the North Atlantic Ocean with  
186 values below 0.2  $\mu\text{g L}^{-1}$  during the major part for the majority of each year with periodic events  
187 of slightly elevated concentrations up to 0.7  $\mu\text{g L}^{-1}$  (van Pinxteren et al., 2020 and refs therein).

188 Submicron aerosol particles were sampled on preheated 150 mm quartz fiber filters  
189 (Munktell, MK 360) at a flow rate of about 700 L min<sup>-1</sup> with a high volume PM<sub>1</sub> aerosol sampler  
190 (Digitel, Riemer, Germany) installed on the 30 m height tower at the coastline. The sampling  
191 times were usually set to 24 h and are listed in Tab. S4 and S5, as well as in Triesch et al., 2021b  
192 and in van Pinxteren et al., 2020). Regarding the aerosol sampling system, it needs to be  
193 underlined that artefact problems and overestimations due to gas phase absorption and  
194 underestimations due to re-volatilisations of the analytes from the filters cannot be accounted  
195 for and represent a certain level of uncertainty.

196 -The seawater samples were taken at Bahia das Gatas, a coastal site that is situated  
197 upwind and of the CVAO about 4 km northwest of the CVAO in front of the station (Fig. S1).  
198 Fishing boats were rented to drive to go out on the open ocean and the SML was sampled with  
199 the a typical glass plate technique as one typical SML sampling strategy (Cunliffe and Wurl,  
200 2014). To this end, a glass plate with a sampling area of 2000 cm<sup>2</sup> was vertically immersed into  
201 the water and then slowly drawn upwards with a withdrawal rate between 5 and 10 cm s<sup>-1</sup>.

202 The surface film adheres to the surface of the glass and is removed using framed Teflon wipers  
203 (Stolle et al., 2010;van Pinxteren et al., 2012). Bulk seawater was collected with a specially  
204 designed device consisting of a plastic bottle mounted on a telescopic rod. The bottle was  
205 opened underwater at depth of 1 m with a specifically conceived seal-opener.

206 For the sampling of the oceanic water samples, great care was taken that all parts that  
207 were in contact with the sample (glass plate, bottles) underwent an intense cleaning with 10%  
208 HCl and rinsing with ultrapure water (resistivity = 18.2 MΩ cm) prior to the campaign and in  
209 between sampling to avoid contamination and carry over problems.

210 After the sampling, all seawater and aerosol samples were stored frozen at -20°C,  
211 transported in a reefer at -20 °C to the TROPOS laboratories where they were stored frozen  
212 until analysis.

213

## 214 2.2 Chemical analysis

215

### 216 2.2.1. Seawater and aerosol analysis: general considerations

217

218 Within the seawater analysis, we measured the dissolved amino acids (DAA) and  
219 dissolved carbohydrates (DCHO) in the DOC fraction, as DOC represents by far the largest pool  
220 of organic material in the ocean (Riebesell et al., 2011). DOC is the fraction of OC that passes  
221 through a GF-F filter of ~~0.2~~–0.7 μm pore size (Wurl, 2009), however, filter pore sizes between  
222 0.2 and 1.2 μm are often applied e.g. due to requirements of the analytical system (e.g.  
223 (Romankevich, 1984;Zäncker et al., 2017). (e.g. Zäncker et al., 2017). The lipid measurements  
224 (from the same samples) were taken from Triesch et al., (2021b), are included in the DOC  
225 fraction as well, being filtered via a 0.7 μm pore-sized filter (GF-F, Whatmann) and extracted  
226 in an organic solvent, and refer to dissolved lipids (DL).

227 For the aerosol particles (PM<sub>1</sub>), we focused on the water-soluble organic (WSOC)  
228 fraction of the amino acids (AA<sub>aer.</sub>) and carbohydrates (CHO<sub>aer.</sub>). The lipids, however, were  
229 extracted with an organic solvent and filtered (analogous to seawater), hence-meaning they  
230 comprise the organic-soluble organic fraction of the aerosol particles (Lipids<sub>aer.</sub>).

231

### 232 2.2.2. Analytical methods

233

234 For the analysis of the DCHO and CHO<sub>aer.</sub> as well as and the DAA and AA<sub>aer.</sub>, molecular-  
235 resolved techniques were applied. DCHO in filtered (0.2 μm Millex syringe filters) and  
236 desalinated SML and bulk water samples as well as CHO<sub>aer.</sub> in the filtered PM<sub>1</sub> extracts were  
237 quantified using High-Performance Anion-Exchange Chromatography coupled with Pulsed  
238 Amperometric Detection (HPAEC-PAD) (Zeppenfeld et al., 2020;Zeppenfeld et al., 2021). After  
239 an acid hydrolysis (0.8 M HCl, 100°C, 20 h) the monosaccharides fucose (Fuc), rhamnose (Rha),  
240 arabinose (Ara), galactose (Gal), glucose (Glc), xylose (Xyl), mannose (Man), galactosamine  
241 (GalN), glucosamine (GlcN), muramic acid (MurAc), galacturonic acid (GalAc) and glucuronic  
242 acid (GlcAc) were measured.

243 For the DAA analysis, seawater samples (25.5 mL) were desalinated and concentrated  
244 to a few mL as described in Triesch et al., (2021a). For the AA<sub>aer.</sub> from PM<sub>1</sub> particles, an aqueous  
245 extract of the amino acids was prepared by shaking a piece of the filter in 2 mL water. After a  
246 filtration step (filter pore size: 0.2 µm) 25 µL of ascorbic acid (20 mg mL<sup>-1</sup>, purity 99 %, Sigma-  
247 Aldrich, St. Louis, Missouri, USA) was added to a 200 µL aliquot of the desalted seawater /  
248 aqueous filter extract to avoid the oxidation of the obtained amino acids as ~~discussed~~  
249 suggested in Mandalakis et al., (2010). Following the addition of 250 µL HCl (Supra-quality,  
250 ROTIPURAN®Supra 35%, Carl Roth, Karlsruhe, Germany), the hydrolysis was performed at  
251 110 °C for 20 h. After cooling to room temperature, the hydrolysed filtrate was evaporated,  
252 resolved in 500 µL milliQ-water (Millipore Elix 3 and Element A10, Merck Millipore, Darmstadt,  
253 Germany), filtered, derivatized using AccQ-Tag™ precolumn derivatization method (Waters,  
254 Eschborn, Germany), and measured by ultra-high performance liquid chromatography with  
255 electrospray ionization and Orbitrap mass spectrometry (UHPLC/ESI-Orbitrap-MS), as  
256 described in Triesch et al., (2021a). The analytes ~~comprise-include~~ the amino acids glycine  
257 (Gly), alanine (Ala), serine (Ser), glutamic acid (Glu), threonine (Thr), proline (Pro), tyrosine  
258 (Tyr), valine (Val), phenylalanine (Phe), aspartic acid (Asp), isoleucine (Ile), leucine (Leu),  
259 methionine (Met), glutamine (Gln) and γ-aminobutyric acid (GABA) (purity ≥ 99 %, Sigma-  
260 Aldrich, St. Louis, Missouri, USA).

261 The DL and Lipids<sub>aer.</sub> measurements were taken from Triesch et al., (2021b), where the  
262 analysis were done with a semi-molecular technique. For a better understanding of the data,  
263 a short description is given in the following: the dissolved fraction of seawater samples  
264 (obtained after filtration through pre-combusted 0.7 µm GF/F filters) and aerosol filters were  
265 extracted with dichloromethane according to specific protocols after adding 2-hexadecanone  
266 as an internal standard, as described in more detail in Triesch et al. (2021b). Seawater or  
267 aerosol filters were extracted with dichloromethane and filtered via GFF (Whatmann, pore  
268 size: 0.7 µm) described in more detail in Triesch et al., (2021b). The ~~filtered~~ extract was  
269 analysed with thin-layer chromatography (TLC). Lipid classes were separated on Chromarods  
270 SIII and calibrated with an external calibration with a mixture of standard lipids by a  
271 chromatograph flame ionisation detector (FID) Iatroscan MKVI (Iatron, Japan). The separation  
272 scheme included elution steps in the solvent systems with increasing polarity. The lipid classes  
273 included hydrocarbons (HC), fatty acid methyl esters (ME), free fatty acids (FFA), alcohols  
274 (ALC), 1,3-diacylglycerols (1,3 DG), 1,2-diacylglycerols (1,2 DG), monoacylglycerols (MG), wax  
275 esters (WE), triacylglycerols (TG), pigments (PIG), phospholipids (PP) including  
276 phosphatidylglycerols (PG), phosphatidylethanolamine (PE), phosphatidylcholines (PC), as  
277 well as glycolipids (GL) which cover sulfoquinovosyldiacylglycerols (SQDG), monogalactosyl-  
278 diacylglycerols (MGDG), digalactosyldiacylglycerols (DGDG) and sterols (ST). It needs to be  
279 underlined that, as no single lipid compound but rather lipid groups (based on varying polarity  
280 in the TLC system) were measured, the lipid results can be classified as analysis on a semi-  
281 molecular level.

282 Organic carbon (OC) on the aerosol particles (PM<sub>1</sub> samples) was measured by means  
283 of a thermal-optical method using the Sunset Laboratory Dual-Optical Carbonaceous Analyzer  
284 (Sunset Laboratory Inc., U.S.A.) from a filter piece with an area of 1.5 cm<sup>2</sup>. The EUSAAR 2

285 temperature protocol was utilized, and a charring correction was applied (Cavalli et al., 2010).  
286 The correction value for pyrolytic carbon was determined based on measurements of a sample  
287 transmission using a 678 nm laser. Samples were thermally desorbed from the filter medium  
288 under an inert He-atmosphere followed by an oxidizing O<sub>2</sub>/He-atmosphere while applying  
289 carefully controlled heating ramps. A flame ionization detector was used to quantify methane  
290 following a catalytic methanation of CO<sub>2</sub>.

291 Sodium was measured from filtered (0.45 µm syringe filter), aqueous extracts of the  
292 PM<sub>1</sub> samples using ion chromatography (more details in Zeppenfeld et al., 2021 and van  
293 Pinxteren et al., 2022). The details on sampling and the sample treatment are summarized in  
294 Tab. S1.

295 Atmospheric concentrations were calculated from the measured analyte  
296 concentrations on the filter or in the filter extract. The masses of the analytes on the filter were  
297 extrapolated to the total filter and related to the collected air volume that flowed through the  
298 filter.

299

### 300 2.2.3 Detection limits and blank handling

301

302 Detection limits were 0.5-2.5 µg L<sup>-1</sup> (DAA) and 0.1-0.2 pg m<sup>-3</sup> (AA<sub>aer</sub>) (Triesch et al.,  
303 2021a;Triesch et al., 2021c) and 0.13-0.7 µg L<sup>-1</sup> (DCHO) and 0.5-5 pg m<sup>-3</sup> (CHO<sub>aer</sub>) (Zeppenfeld  
304 et al., 2021). Regarding the lipids, -the method was carefully optimized for seawater analysis  
305 (Gašparović et al., 2015, 2017) and adopted for aerosol particle analytics as described in  
306 Triesch et al., (2021b). The detection limits were determined as the analyte concentrations  
307 corresponding to a signal-to-noise (S/N) ratio of 3 ranged from 0.06 to 0.33 µg as reported  
308 previously in Penezić et al. (2022).

309 For the seawater analysis, field blanks were taken by filling high-purity water in pre-  
310 cleaned plastic bottles and handled the same as the seawater samples. The seawater blanks  
311 in general below 10% and for the lipids always below 15% (Triesch et al. 2021b). All data are  
312 blank corrected by subtracting the field blank values from the samples.

313 Field blanks for aerosol particles were prepared using pre-baked quartz fiber filters  
314 without an active sampling and treated according to the same procedure as the field samples.  
315 The concentrations of the target analytes were calculated by external calibration. Each sample  
316 was measured twice with a relative standard deviation of typically < 10 %, and field blanks,  
317 which were for most compounds negligible and for the lipid classes always below 20% of the  
318 real aerosol particle sample, were subtracted. All presented values are corrected for the field  
319 blank.

320

321

### 322 2.3 Enrichment factors

323

324 The SML enrichment factor (EF<sub>SML</sub>) was calculated by dividing the concentration of the  
325 analyte in the SML with the concentration of the analyte in the bulk water after equation (1):

326

$$EF_{SML} = \frac{c(\text{analyte})_{SML}}{c(\text{analyte})_{bulk\ water}} \quad (1)$$

328

329 An enrichment in the SML is indicated with  $EF_{SML} > 1$  and a depletion in the SML with  $EF_{SML} < 1$ .

330 The enrichment factor of aerosol ( $EF_{aer.}$ ) is a quantitative metric for comparing  
 331 compounds in the ocean and in the atmosphere. The  $EF_{aer.}$  concept is mainly applied to closed  
 332 systems (Quinn et al., 2015 and refs. therein; Rastelli et al., 2017) as degradation and formation  
 333 pathways on aerosol particles including photochemical and biotic atmospheric reactions and  
 334 contributions from other (non-marine) sources are excluded from this parameter.  
 335 Nevertheless, for comparison purposes, it is useful to apply the  $EF_{aer.}$  to open systems as well,  
 336 as shown in several studies (Russell et al., 2010; Triesch et al., 2021a; Triesch et al., 2021b; van  
 337 Pinxteren et al., 2017; Zeppenfeld et al., 2021). To this end, the concentration of the analyte  
 338 of interest in each compartment is related to the respective sodium concentration (equation  
 339 2), because sodium is regarded as a conservative sea salt tracer transferred to the atmosphere  
 340 in the process of bubble bursting (Sander et al., 2003).

341

$$EF_{aer.} = \frac{c(\text{analyte})_{aer.}/c(Na^+)_{aer.}}{c(\text{analyte})_{seawater}/c(Na^+)_{seawater}} \quad (2)$$

343

344 To account for the different timescales for ocean and atmospheric processes and to  
 345 improve robustness, we applied the average concentration values of the respective compound  
 346 groups in seawater and on aerosol particles as done by (Zeppenfeld et al., 2021; van Pinxteren  
 347 et al., 2022). It should be noted that  $EF_{SML}$  and  $EF_{aer.}$  comparisons include samples from the  
 348 same campaign but not necessarily from the same exact date (details in Tab.1 and Tab S2-S5).  
 349 However, as our focus was not on showing trends within the campaign (this was covered by  
 350 Triesch et al., 2021a,b) but rather on comparing the three different OC groups with each other,  
 351 the usage of average values is justified. To investigate the variability of the  $EF_{aer.}$ , the minimum  
 352 ratio of  $c(\text{analyte})_{aer.}/c(Na^+)_{aer.}$  vs. the maximum ratio of  $c(\text{analyte})_{seawater}/c(Na^+)_{seawater}$  was applied  
 353 and vice versa. As seawater concentration, the bulk water or the SML concentration can be  
 354 applied.

355 Statistical significance was evaluated using the analysis of variance (ANOVA).

356

357

### 358 3. Results and Discussion

#### 359 3.1 SML and ~~b~~Bulk water

##### 360 3.1.1 Concentration and composition of the dissolved amino acids (DAA), dissolved 361 carbohydrates (DCHO) and dissolved lipids (DL)

362 Figure 1 shows the analyte concentrations in the bulk ocean water (DAA:  $80 \pm 53 \mu\text{g L}^{-1}$   
 363  $^1$ , DCHO:  $78 \pm 15 \mu\text{g L}^{-1}$ , DL:  $70 \pm 25 \mu\text{g L}^{-1}$ ) and in the SML (DAA:  $190 \pm 238 \mu\text{g L}^{-1}$ , DCHO:  $85 \pm$   
 364  $30 \mu\text{g L}^{-1}$ , DL:  $83 \pm 24 \mu\text{g L}^{-1}$ ). Hence, the average concentrations for DCHO and DL are similar

365 in the bulk water and in the SML (detailed values in Sect. 2.2.2, Tab. 1 and DL concentrations  
 366 can be found in Triesch et al., (2021b)). For the DAA, however, SML concentrations show a  
 367 larger variability compared to the other compounds and ~~compared to the~~ bulk water.  
 368 However, despite the variability of the DAA in the SML, they are not statistically different to  
 369 the other two compound groups (DL and DCHO) as well as to the DAA in the bulk water (Anova  
 370 one way,  $p > 0.5$  at the 0.5 level) that is different in the case of free amino acids (FAA). In total,  
 371 no significant difference is present between the compound groups within the SML and the  
 372 ULW (Anova one way,  $p > 0.5$  at the 0.5 level). -Resulting from the higher SML concentrations,  
 373 the average SML enrichment factors of DAA is  $2.34 \pm 0.3$  (Tab.1) and therefore higher  
 374 compared to the DCHO ( $EF_{SML} = 1.1 \pm 0.5$ ) and DL ( $EF_{SML} = 1.3 \pm 0.2$ ). The high variability of the  
 375 DAA concentrations agreed well with the ~~free amino acids (FAA)~~ that comprise the sum of  
 376 unbound individual amino acids i.e. not bound in a peptide or protein and were measured at  
 377 this location during the MarParCloud campaign (Triesch et al., 2021a). However, the FAA in  
 378 the SML were significantly higher compared to the FAA in the bulk water (Triesch et al., 2021a).  
 379 ~~In addition,~~ other studies have pointed out highly variable amino acid concentrations as well,  
 380 for example, Zänker et al., (2017) showed FAA concentrations between 32 and 1268 nmol L<sup>-1</sup>  
 381 and DAA varied between 202 and 2007 nmol L<sup>-1</sup> (for comparison: the here presented DAA  
 382 values correspond on average to 1064 nmol L<sup>-1</sup> in the bulk water and 2536 nmol L<sup>-1</sup> in the  
 383 SML). High enrichments of FAA in the SML were reported (Kuznetsova and Lee,  
 384 2002;Kuznetsova et al., 2004;Reinthalder et al., 2008;van Pinxteren et al., 2012;Engel and  
 385 Galgani, 2016) with FAA enrichments up to 300 in the SML of the Cape Verde seawaters  
 386 (Triesch et al., 2021a). A preferential enrichment of FAA over dissolved combined amino acids  
 387 as a consistent microlayer feature was proposed (Kuznetsova et al., 2004).

388

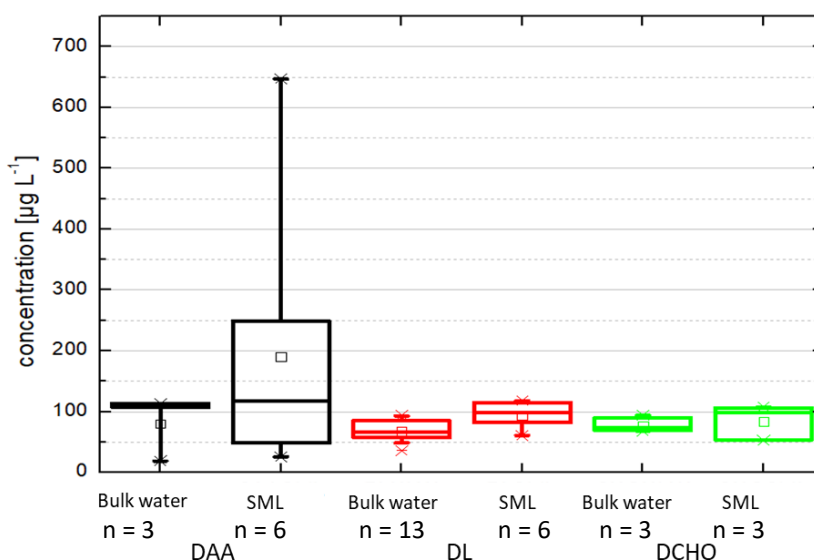

Figure 1

389

390

391

392

Regarding the composition of the individual DAA measured here, clear differences  
 between the SML and the bulk water characteristics were observed (Fig. 2, blue and orange  
 bars, data in Tab. S21 - 54). Besides the higher concentrations in the SML, some DAA were

393 only present in the SML and not in the bulk water (below detection limit). This was most  
 394 pronounced for Glu, but also evident for Tyr and Iso (detailed values in Tab. S32).

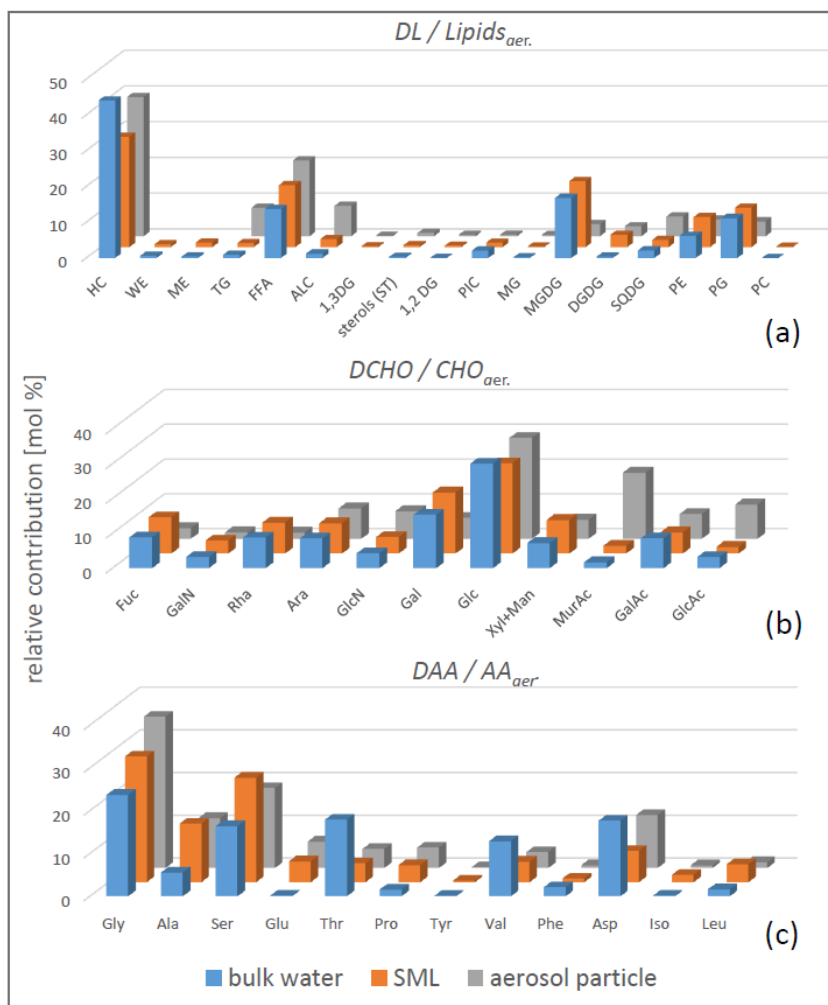

Figure 2

395 In contrast to the DAA, the DCHO enrichment in the SML was less pronounced with an  
 396  $EF_{SML}$  of  $1.1 \pm 0.5$  (Tab. 1), similar to SML enrichment values obtained for DCHO close to the  
 397 Peruvian upwelling regime (Zänker et al., 2017) and the Antarctic Peninsula (Zeppenfeld et  
 398 al., 2021). Regarding the relative composition, the DCHO showed a very homogeneous pattern  
 399 and were similar in the SML and the bulk water (Fig. 2, blue and orange bars).

401 The enrichment of the DL ( $EF_{SML} = 1.3 \pm 0.2$ , Tab. 1) was very similar to the DCHO  
 402 enrichment and is discussed in Triesch et al., (2021b). From the individual lipid components  
 403 and the lipolysis index, it was concluded that the lipids were degraded only to a small extent  
 404 (Triesch et al., 2021b).

405 Altogether, the high and varying concentrations and enrichments of DAA in the SML in  
 406 contrast to the DCHO and DL concentrations underline that significant changes occur for the  
 407 DAA in the SML that are less pronounced for the other two compound groups. However, it is  
 408 important to mention that the number of samples that have been analysed is different and  
 409 limited (Tab. 1 and Fig. 1) and samples from partly different dates of the campaign have been  
 410 analysed and compared.

411

### 412 3.1.2 Discussion of the SML enrichment

413

#### 414 3.1.2.1 Surface vs bulk SML

415

416 The SML enrichment of DOC components is generally attributed to diffusion, turbulent  
417 mixing, as well as scavenging, and transport of surface-active matter from rising gas bubbles  
418 in the water column (Liss and Duce, 1997). Within the ~~groups here~~-investigated ~~group~~here,  
419 the DL are the most hydrophobic compounds and are generally classified as highly surface-  
420 active compounds (Burrows et al., 2014). Although the surface-activity parameters (e.g.  
421 octanol-water partition coefficient, density, Topological Polar Surface Area) of the individual  
422 lipids differ among each other (values in Triesch et al., (2021b)), the lipids are overall more  
423 non-polar and surface active compared to the carbohydrates and amino acids (values in  
424 Triesch et al., 2021a ). Nevertheless, the enrichment of the DL in the SML was significantly  
425 lower compared to the carbohydrates and amino acids. This was obvious from a comparison  
426 of the averaged values as well as from single samples obtained at the same date (03.10.2017  
427 and 07.10.2017, values in Tab. S2, S3, and Triesch et al. 2021b).

428 One explanation for the finding lies in the sampled SML thickness. With the glass plate  
429 technique, an SML thickness of about 100  $\mu\text{m}$  ~~is has typically been~~ sampled ~~and reported for~~  
430 ~~the CVAO area~~ (van Pinxteren et al., 2017). Hence, the 100  $\mu\text{m}$ -thick SML might be very well-  
431 mixed with regards to the soluble amino acids and carbohydrates, however the surface-active  
432 compounds, such as ~~the~~ lipids, are potentially located on the very top and form a thin (nm-  
433 thick) monolayer. In the literature, the SML is described either as a series of sub-layers of wet  
434 and dry surfactants (Hardy, 1982) or as a gelatinous matrix (Sieburth, 1983). Independent of  
435 the model, it can ~~well~~-be expected that a gradient along the surface likely forms with  
436 surfactants at the very top of the layer. The formation of a lipid-rich nanolayer on the very top  
437 agrees with surface-sensitive spectroscopy measurements that are able to tackle the  
438 uppermost layer and found strong indications for a nanolayer dominated by soluble  
439 surfactants (Lass and Friedrichs, 2011) and hydrophobic low molecular weight lipids (Frka et  
440 al., 2012). The nanolayer ~~is~~, however, ~~not accessible~~~~cannot be probed~~ with currently applied  
441 ~~bulk~~-SML sampling methods. Therefore, the measured SML concentrations may represent a  
442 very diluted (likely highly lipid-enriched) layer. Consequently, the SML structure is even more  
443 complex, which needs to be considered, ~~notably~~-~~particularly~~ when discussing lipid  
444 enrichments in the SML. Here, a combination of bulk measurements with dedicated surface  
445 probing appears highly desirable.

446

#### 447 3.1.2.2 Details of SML enrichment mechanisms

448

##### 449 (i) Co-adsorption ~~and complexation~~

450

451 Regarding the DAA in detail, it is interesting to note that some compounds are  
452 exclusively present in the SML, as mentioned above. They belong to hydrophilic (Glu),  
453 hydrophobic (Iso) and neutral (Tyr) fractions of amino acids, underlining that their occurrence

454 in the SML might not be related (solely) to their physicochemical properties. Besides an air  
455 bubble-driven transfer to the surface, enrichment in the SML can be supported by co-  
456 adsorption mechanisms. Less surface-active compounds (e.g. amino acids and carbohydrates)  
457 can be attached due to ionic interactions/coulomb interactions to the head groups of the air  
458 bubble-attached surfactants (e.g. lipids) that mediate their enrichment in the SML (Burrows  
459 et al., 2016;Hasenecz et al., 2019;Link et al., 2019;Schill et al., 2018). Co-adsorption can  
460 provide an explanation for the high occurrence of non-surface active, very soluble  
461 compounds, such as carbohydrates. A recent laboratory study showed different mechanisms  
462 for the co-adsorption of polysaccharides that form a second calcium-bridges sublayer  
463 underneath the monolayer whereas monosaccharides intercalate and induce reorganisation  
464 within the nanolayer (Vazques de Vasquez et al., 2022). However, in the current study, only a  
465 small SML enrichment of the DCHO and, hence, no indication for a strong co-adsorption was  
466 observed.

467

468 (ii) In-situ processing: Abiotic vs. biotic

469

470 Further explanations for the accumulation of dissolved compounds require ~~an~~ in situ  
471 formation or degradation by SML-specific reactions that might be triggered by distinct  
472 environmental conditions in the SML. Biotic pathways and abiotic SML-specific  
473 (photo)chemical reactions may strongly impact OC cycling at the sea surface (Liss and Duce,  
474 1997). The high abundance of the amino acid Glu in the SML observed here was also reported  
475 in the FAA fraction by Triesch et al., (2021a) and can likely be explained by in situ formation.  
476 In incubated cloud water as another marine compartment, Glu has been shown to be  
477 produced via biotic and abiotic mechanisms, e.g. via the oxidation of proline (Jaber et al., 2021  
478 and refs. therein) and such processes may be relevant in the ocean surface as well. Regarding  
479 biotic processes, it is well-known that microorganisms have complex and highly  
480 interconnected enzymatic networks and ~~are able to~~can biodegrade or biosynthesize organic  
481 compounds (KEEG pathway). Kuznetsova and Lee (2002) suggested that stressed  
482 microorganisms, rich in dissolved and combined amino acids, may be leached and released  
483 them, which in turn affects the pools of both these compounds in seawater. Although such  
484 formation mechanisms generally happen in the upper ocean, there are indications for SML-  
485 specific processes. Along a transect from upwelling regions toward oligotrophic gyres it was  
486 found that while in the bulk water a clear trend toward degradation of amino acids was  
487 observed, the production and degradation patterns of amino acids in the SML were much  
488 more complex (Reinthaler et al., 2008). This is indicative of the role of the SML in the  
489 production of labile DOC driven by coupled microbial and photochemical processes. Similarly,  
490 Kuznetsova and Lee (2001) observed that peptide turnover was always faster in the SML than  
491 in subsurface waters likely due to the greater concentrations of DOC in the SML. The authors  
492 concluded that the accumulation of organic and inorganic compounds in the SML leads to a  
493 more nutritious medium for microbial growth and consequently enzymatic hydrolytic activity  
494 compared to the bulk water. Connecting this to the results presented here, this might suggest  
495 that changes induced by abiotic and biotic processing need to be considered when regarding

496 the SML composition. Although such reactions likely also affect lipids and carbohydrates, they  
497 seem to be most pronounced for amino acids.

498

499

500 (iii) Microbial nitrogen fixation at the sea-air interface

501

502 A further mechanism contributing to the high and variable SML enrichment of the DAA

503 at the current location might be ~~a~~-microbial nitrogen fixation at the sea-air interface.

504 Measurements showed that cyanobacteria are a very pronounced phytoplankton group in this

505 region (Franklin et al., 2009; Hepach et al., 2014; Zindler et al., 2012), which was dominant

506 during the MarParCloud campaign (van Pinxteren et al., 2020). Cyanobacteria are able to take

507 up nitrogen from the atmosphere (Zehr, 2011). Earlier studies showed that cyanobacteria-

508 fixed nitrogen is incorporated into amino acids (specifically glutamine (Carpenter et al., 1992)).

509 The calculated net amino acids release from cyanobacteria colonies (*Trichodesmium*

510 *thiebautii*) revealed that nitrogen fixation and the biogeochemical turnover of ambient amino

511 acids are an important source of recently fixed (“new”) nitrogen within the oceanic surface

512 water (Capone et al., 1994). These considerations are, however, highly speculative and

513 demand further studies to investigate if nitrogen fixation and biosynthesis via cyanobacteria,

514 which ~~occurs broadly is often observed~~ in subtropical and tropical oceans (Montoya et al.,

515 2007), might establish a considerable route for amino acid formation and enrichment in the

516 SML from the atmospheric side.

517

518 (iv) Concluding remarks towards the SML enrichment

519

520 Although SML enrichment factors for amino acids, carbohydrates, and lipids have been

521 reported in the available literature, they have not previously been shown in such detailed

522 analysis for samples collected from the same site as ~~was the case shown~~ here. From this study

523 it can be concluded that the amino acids are strongly enriched in the SML compared to

524 carbohydrates and lipids, even under the same environmental conditions. In a recent study

525 we showed a strong enhancement of other nitrogen-containing species (aliphatic amines) in

526 the SML at this location, while the amine concentration in the bulk water was often not

527 detectable (van Pinxteren et al., 2019). This suggests that the pronounced SML enrichment

528 specifically exists for nitrogen-containing organic species. In addition, the absence of a relation

529 of the SML enrichment to physical compound parameters (e.g. hydrophobicity) suggests that

530 enrichment processes based on physicochemical properties (e.g. surface-activity) alone do not

531 drive SML enrichment. Rather, an SML in situ formation mechanism impacts the abundance

532 of amino acids and likely nitrogen-containing organic species in general.

533

534 3.2. Aerosol particles

535 3.2.1 Concentration and composition

536

537 After evaluating the concentrations of the analytes in seawater and the SML, in the  
538 next step, their presence in the aerosol particles was investigated. The concentrations of AA<sub>aer</sub>  
539 and CHO<sub>aer</sub> were 2.4 ± 1.1 ng m<sup>-3</sup> and 1.0 ± 1.1 ng m<sup>-3</sup>, respectively (Fig. 3, Tab. 1) and not  
540 significantly different ULW (Anova one way, p > 0.5 at the 0.5 level).

541

542 Compared to results from the Polar Regions, the CHO<sub>aer</sub> concentrations in the tropical  
543 Atlantic Ocean analysed here are at the lower end. Leck et al., (2013) determined  
544 carbohydrates during the Arctic summer and found 0.7 - 20 ng m<sup>-3</sup> in submicron particles.  
545 Zeppenfeld et al., (2021) found carbohydrate concentrations between 0.2 - 11.3 ng m<sup>-3</sup> in PM<sub>10</sub>  
546 atmospheric particles, in the Western Antarctic Peninsula, which contributed about 3% to the  
547 OC. The same holds true for amino acids, the concentrations found here are slightly lower as  
548 reported for other marine regions, e.g. FAA in Antarctic aerosol particles were on average 4.6  
549 ng m<sup>-3</sup> in Antarctic aerosol (Barbaro et al., 2015). Triesch et al., (2021a) found FAA  
550 concentrations between 1.5 and 3.0 ng m<sup>-3</sup> in the aerosol particles from the Cape Verdes. The  
551 AA<sub>aer</sub> are generally in the same order of magnitude compared to other marine locations  
552 (Matos et al., 2016; Matsumoto and Uematsu, 2005; Renard et al., 2022; Wedyan and Preston,  
553 2008). However, concentrations of amino acid and carbohydrates in urban, rural, and forest  
554 areas are significantly higher (2-3 orders of magnitudes) compared to the values and the  
555 spectrum of compounds is strongly shifted (e.g. (Dominutti et al., 2022; Samake et al.,  
556 2019; Zhu et al., 2022).

557 Comparing the data obtained here with those ~~provided by~~ from analytical techniques  
558 that use functional group information (FT-IR) has shown ~~ed~~ that the latter techniques often  
559 ~~report~~ attribute a large fraction of alcohol (hydroxyl) functional groups on the marine aerosol  
560 particles ~~identified and attributed to carbohydrates~~ (Cravigan et al., 2020; Frossard et al.,  
561 2014; Russell et al., 2010). According to Russell et al., (2010), the primary marine signal in  
562 submicron marine aerosol over the North Atlantic and Arctic Oceans is made on average for  
563 88% of hydroxyl groups corresponding to carbohydrate-like material. Such high fractions of  
564 carbohydrates were not found in the chromatographic analysis of CHO<sub>aer</sub> presented here, nor  
565 in other studies using similar methodologies (e.g. Zeppenfeld et al., 2021). In a recent study,

566 using thermal desorption mass spectrometry, it was suggested that carbohydrates only  
567 represented a minor fraction of the FT-IR alcohol group and another thermally stable fraction,  
568 different to carbohydrates, was the main contributor to the alcohol group (Lawler et al.,  
569 (2020)). Hence, previous FT-IR measurements might have over-predicted the carbohydrate  
570 fraction of marine aerosol particles and further (molecular-based) analysis should be  
571 conducted in comparison to resolve existing contradictions.

572 In contrast to the  $\text{CAA}_{\text{aer}}$  and  $\text{CHO}_{\text{aer}}$ , the  $\text{Lipid}_{\text{aer}}$  concentrations were  $120 \pm 43 \text{ ng m}^{-3}$  and  
573 therefore two orders of magnitude higher than the other two organic groups (Fig. 3, Tab. 1)  
574 The  $\text{Lipid}_{\text{aer}}$  were significantly higher than the  $\text{AA}_{\text{aer}}$  ( $p = 6.6\text{E-}13$ ) and the  $\text{CHO}_{\text{aer}}$  ( $p = 1.6\text{E-}7$ )  
575 (Anova one way, at the 0.5 level). One possible reason for the higher  $\text{Lipid}_{\text{aer}}$  concentration  
576 could lay in the difference in the extraction procedure (chapter 2.2) as  $\text{AA}_{\text{aer}}$  and  $\text{CHO}_{\text{aer}}$  were  
577 extracted in water, while the  $\text{Lipid}_{\text{aer}}$  were extracted in an organic solvent. Previous lipid  
578 analysis on a molecular level revealed concentrations between  $0.19 - 23 \text{ ng m}^{-3}$  for ALC and  
579 between  $2.5 - 38 \text{ ng m}^{-3}$  for free fatty acids on marine aerosol particles from the western North  
580 Pacific (Kawamura et al., 2003) and a recent study found marine fatty acid concentrations  
581 between  $50$  and  $90 \text{ ng m}^{-3}$  in coastal aerosol at Qingdao (Chen et al., 2021). Mochida et al.,  
582 (2002) observed saturated fatty acids (C14–C19) on marine aerosol particles over the northern  
583 Pacific in atmospheric concentration between  $0.8 - 24 \text{ ng m}^{-3}$ . Hence, these data are in the  
584 same order of magnitude as here measured lipid groups (ALC:  $6.3 \text{ ng m}^{-3}$ , free fatty acids:  $18.5$   
585  $\text{ ng m}^{-3}$ , values in Triesch et al., 2021b). Cochran et al. (2017) showed that lipid components  
586 (long-chain fatty acids) comprised a significant fraction of up to 75% of the identified organic  
587 constituents in aerosol particles from a sea spray tank.

588 A recent study using FT-ICR-MS found that among a large number of molecular  
589 formulas, large peak numbers were assigned to proteins and lignins (phenolic  
590 macromolecules) followed by carbohydrates and lipids in aerosol originating from the Arctic  
591 ocean (vs. non-ocean aerosol) (Choi et al., 2019).

592 High lipid fractions in marine aerosol particles were also reported from NMR  
593 measurements. Measurements of nascent aerosol particles produced from North Atlantic  
594 seawater showed that the water-soluble organic aerosol fraction was purely aliphatic with  
595 hydroxylated moieties of sugars, esters, and polyols, aliphatic groups adjacent to carbonyls,  
596 amides, and acids, as well as aliphatic chains with terminal methyl-groups, typical of lipids  
597 (Facchini et al., 2008). The water-insoluble organic fraction was dominated by  
598 lipopolysaccharides, known as phytoplankton exudate components. A recent study applying  
599 NMR analysis to artificially produced aerosol particles after bubbling seawater from offshore  
600 areas also showed proof of polyols and lipids (Decesari et al., 2020). NMR measurements of  
601 lipids are mainly qualitative, however, the high fraction of lipid-like components from other  
602 regions agrees well with the ~~here presented~~ high  $\text{Lipid}_{\text{aer}}$  concentrations presented here.

603 A high  $\text{Lipid}_{\text{aer}}$  concentration as observed in the present study agrees well with the modelling  
604 results of Burrows et al., (2014), where the ocean-atmosphere transfer was calculated  
605 according to the physicochemical properties of the distinct OC groups. Lipids, as the most  
606 surface active OC group comprise the largest fraction of the aerosol fraction, although their  
607 (modelled) concentration in the seawater is lower compared to carbohydrates and amino

608 acids (Burrows et al., 2014). In a latter model modification, where additional co-adsorption  
609 processes were included in the calculations, a more pronounced saccharidic fraction was  
610 determined on the aerosol particles from the model results (Burrows et al., 2016), that is  
611 different from the findings here, at least regarding the  $CHO_{aer}$  measured on a molecular level.  
612 However, it needs to be considered that the lipids analysed here include glycolipids (MGDG,  
613 DGDG, SQDG) which are components that have the solubility properties of a lipid but also  
614 contain one or more sugar molecules. The glycolipids comprise a non-negligible portion of the  
615 OC on the aerosol particles (values in Table S6 and S8). This underlines the complexity of  
616 attributing the OC to distinct organic groups and demonstrates that the applied analytical  
617 methods must be taken into account when comparing concentrations of substance groups.  
618 This is discussed in more detail in 3.4.1. Altogether, there seems to be a discrepancy between  
619 the measured concentrations and the modelled results underlining that the transfer of the  
620 organic compounds from the ocean to the atmosphere based on their physicochemical  
621 properties might not be the only mechanism.

622

### 623 3.2.2 Aerosol enrichment

624

#### 625 3.2.2.1 Aerosol enrichment factors

626 The finding that the  $Lipids_{aer}$  were much higher concentrated than the  $AA_{aer}$  and the  
627  $CHO_{aer}$ , resulted in a very different pattern compared to the similar seawater concentrations  
628 (Fig. 1 vs. Fig. 3). To quantitatively compare the seawater and the aerosol concentration, the  
629  $EF_{aer}$  was calculated (values in Tab.1).

630

631

#### ***Insert Table 1***

632

633 For the amino acids the  $EF_{aer}$  was between  $9.2 \times 10^2$  (related to the SML) and  $2.1 \times 10^3$   
634 (related to the bulk water) and on average  $1.5 \times 10^3$ . For the carbohydrates the  $EF_{aer}$  was  
635 between  $1.3 \times 10^3$  (related to the SML) and  $1.4 \times 10^3$  (related to the bulk water) and on average  
636  $1.3 \times 10^3$  and therefore similar to the  $EF_{aer}$  of the amino acids. For the lipids, however, the  $EF_{aer}$   
637 was two orders of magnitude higher ( $EF_{aer} = 1.4 \times 10^5$ , related to the SML;  $EF_{aer} = 1.7 \times 10^5$   
638 related to the bulk water,  $EF_{aer} = 1.6 \times 10^5$  on average, Tab. 1).

639

#### 640 3.2.2.2 Oceanic transfer and atmospheric in situ formation

641 The overall high enrichment of OC in the aerosol particles is explained by complex, not  
642 yet ~~finally-~~ resolved interactions at the ocean surface where organic matter is enriched ~~over~~  
643 relative to sodium during the formation of film and jet droplets. Burrows et al., (2014) applied  
644 a conceptual model ("slab" model) where all organics partition to the surface of a "slab" of  
645 oceanic water or to both the outer and inner surfaces of a bubble film. The organic enrichment  
646 is therefore significantly higher for the thinner bubble films (bubble film thicknesses: 0.01 to  
647 1  $\mu\text{m}$ ) than for the thicker SML (typically sampled SML thicknesses: 20 to 400  $\mu\text{m}$ ). This

648 mechanism can explain an  $EF_{aer.}$  of OC in submicron aerosol particles of  $10^2$  to  $10^3$  compared  
649 to the SML (Burrows et al., 2014). However,  $EF_{aer.}$  from ambient and laboratory-controlled  
650 observations show that for some compounds even higher  $EF_{aer.}$  are obtained. In a controlled  
651 tank study, Rastelli et al., (2017) found strong enrichments for lipids (up to  $1.4 \times 10^5$ ), as well as  
652 for proteins (up to  $1.2 \times 10^5$ ) and carbohydrates (up to  $1.0 \times 10^5$ , Tab. 1). A recent controlled  
653 bubble-bursting laboratory study showed that amino acids enrichments can be up to  $10^7$  in  
654 submicron SSA between 0.029 and 0.060  $\mu\text{m}$  (Triesch et al., 2021c). Similarly, Schmitt-Kopplin  
655 et al., (2012) showed that surface-active biomolecules are preferentially transferred from  
656 surface water into the atmosphere via bubble bursting. The ambient enrichment factor of the  
657 lipids ( $10^5$ ) shown here and in Triesch et al., (2021b) agreed well with laboratory-derived ones  
658 (Rastelli et al., 2017) indicating that the transfer mechanisms simulated in lab experiments  
659 agree with here performed observations in the field. Hence, the high surface activity and/or  
660 the lipophilic character of the lipid classes might explain their strong (chemo-selective)  
661 transfer to the aerosol particles. Even though the lipid composition on the aerosol particles  
662 slightly varied from the seawater concentration (Triesch et al., 2021b), their transfer is likely  
663 driven by their physicochemical properties (high surface activity and/or the lipophilic  
664 character). For the amino acids and carbohydrates, however, more complex mechanisms may  
665 determine their transfer to the atmosphere. Rastelli et al., (2017) suggested that diverse  
666 biological processes on the ocean drive the properties of proteins and carbohydrates in the  
667 ocean surface and in the atmosphere. Moreover, these compounds are known to be involved  
668 in marine gel-like particle formation, such as transparent polymer particles (TEP) and  
669 coomassie stained particles (CSP), observed in the ocean and more recently in the atmosphere  
670 (Aller et al., 2017; Kuznetsova et al., 2005; van Pinxteren et al., 2022) adding more complexity  
671 to the system. Hence not only a sea-to-air transfer but also atmospheric in situ formation and  
672 degradation might determine the concentration of the OC and notably of the amino acid and  
673 carbohydrates. This suggests that atmospheric processing plays an important role besides the  
674 physical-driven bubble bursting sea-air transfer of OC.

675

### 676 3.2.3 Limitations of the concept of an aerosol enrichment factor

677

678 When comparing OC in the ocean and the atmosphere, it needs to be considered that  
679 processes in the ocean and the atmosphere happen on different timescales. In addition, the  
680 seawater samples comprise spot samplings in the ocean while the sampling period of  $\text{PM}_{10}$   
681 aerosol particles at the CVAO covers a time span of 24h. These issues make a comparison  
682 between the ocean and atmospheric data very challenging. However, the air masses arriving  
683 at the CVAO often followed the water current (Pena-Izquierdo et al., 2012; van Pinxteren et  
684 al., 2017) and suggest a strong link between the upper ocean and the aerosol particles, as  
685 mainly winds drive the ocean currents in the upper 100 m of the ocean. Besides the ocean,  
686 Saharan dust is a strong aerosol source at the Cape Verde islands, most pronounced in the  
687 months December to February (Fomba et al., 2014). The backward trajectories during the time  
688 of the campaign (Fig. S2) as well as the mass concentrations of inorganic ions and mineral dust  
689 tracers on the aerosol particles measured during the campaign suggested a predominant

690 marine origin with low to medium dust influences (van Pinxteren et al., 2020). Moreover, dust  
691 generally influences the supermicron particles to a larger extent than the submicron particles  
692 analysed here (Fomba et al., 2013). Hence, although different factors certainly affect the  
693 aerosol composition, it is reasonable to assume a strong oceanic contribution.

694  
695

### 696 3.3. Seawater and aerosol particles: Comparison of the relative composition

697         Regarding the organic components on the aerosol particles, the same compounds that  
698 were present in the seawater were generally present on the aerosol particles (Fig. 2, grey bars,  
699 and values in Tab. S21 - 54). However, the relative composition of distinct compounds was, at  
700 least partly, different. Regarding the carbohydrate composition, the percentages of MurAc,  
701 GlcAc, and GlcN in the aerosol particles were higher compared to the seawater. MurAc and  
702 GlcN are important constituents in the cell walls of marine microorganisms and notably,  
703 MurAc serves as a proxy for bacterial biomass (Mimura and Romano, 1985). Its high  
704 concentration might indicate an enrichment of bacteria on the aerosol particles. Zeppenfeld  
705 et al., (2021) detected similar (biogenic) carbohydrates in particles sampled in the western  
706 Antarctic peninsula and suggested that marine bacteria in atmospheric particles may  
707 metabolize a part of the oceanic carbohydrates in a selective enzymatic way analogous to the  
708 bacterial processes in seawater. Such processes might explain the changed carbohydrate  
709 composition and are likely not restricted to a specific oceanic regime, as they seem to happen  
710 in the Southern Ocean (Zeppenfeld et al., 2021) as well as in the tropical Atlantic Ocean,  
711 observed here. The elevated relative occurrence of GlcAc found here agrees well with the  
712 recent finding of a high abundance of gel-like material in aerosol particles at the CVAO,  
713 strongly enriched towards sodium compared to seawater (van Pinxteren et al., 2022) as GlcAc  
714 is one main component of marine gelatinous exopolysaccharides (Casillo et al., 2018; Krembs  
715 et al., 2002). Regarding the lipids, surfactants such as free fatty acids as well as lipophilic  
716 compounds, such as hydrocarbons, had major contributions in the seawater and on the  
717 aerosol particles, respectively. However, TG, an energy storage lipid, had a higher contribution  
718 to the aerosol particles versus the ocean water. In addition, some other, minor-contributing  
719 lipid classes were partly different ~~in the two compartments~~within ocean and atmosphere  
720 (Triesch et al., 2021b).

The most remarkable difference in relative composition in seawater and in aerosol particles was found for amino acids, as some DAA were clearly present in the SML and in the aerosol particles but not in the bulk water (e.g. Iso and Glu, Fig. 4, individual values in Tab. S65). The amino acids generally differed a lot regarding their SML and bulk water composition. This was visible in the data set presented here for the DAA, and also reported for the FAA measured from the same campaign (Triesch et al., 2021a). Recently it was reported that the acidic amino acid Glu (in the form of FAA) is transferred to SSA to a large extent (Triesch et al., 2021c) and the results of the present study suggest that Glu might be transferred solely from the SML (and not from the bulk water) to the aerosol particles. However, besides the oceanic transfer, Glu can result from an in situ formation on the aerosol particles. Similarly to the seawater, Glu might form from biotic or abiotic reactions on the aerosol particles. From the ~~here performed~~ measurements performed here it is not possible to differentiate between a selective transfer of Glu from the SML and its biotic and abiotic in situ formation in aerosol particles. Recently, Jaber et al., (2021) and Renard et al., (2022) evaluated the atmospheric aging of the amino acids and considered biotic and abiotic (mainly oxidation) processing. Their calculations revealed different atmospheric lifetimes for the individual amino acids related to oxidation and biological processes, respectively. For example, the amino acids Ser and Ala are degraded quickly by biological processes (lifetime of a few hours) but are more stable towards oxidation (Renard et al., 2022). Such studies can help to understand the patterns of the amino acids as observed here and relate them to sources and atmospheric processing. The presence of Ser and Ala in the ~~here investigated~~ aerosol particles investigated here could therefore indicate that biodegradation of these compounds was not pronounced. However, additional studies are needed to better understand atmospheric biotic and abiotic processing. In

748 addition, the transfer of individual DAA exclusively from the SML shall be investigated in  
749 further research, preferably within characterized and controlled bubbling systems.

750

### 751 3.4 Contribution to aerosol particle OC

752

#### 753 3.4.1 Molecular and semi-molecular analysis

754 OC concentrations in marine aerosol particles during this campaign varied between  
755 0.13 and 0.31  $\mu\text{g m}^{-3}$  with an average value of 0.20  $\mu\text{g m}^{-3}$  (values in Tab. S76). This agreed well  
756 with previous OC measurements from the CVAO that were on average 0.27  $\mu\text{g m}^{-3}$  OC (van  
757 Pinxteren et al., 2017). To date, only a small percentage of OC on marine aerosol particles is  
758 characterised on a molecular level and organic biomarkers often comprise only a few percent  
759 of the OC (Chen et al., 2021). Fu et al., (2011) measured more than 140 different single organic  
760 species in marine aerosol from different oceanic areas, however the identified species  
761 composed less than 5.7% of the OC. Taking together the OC components described here  
762 (Lipids<sub>aer.</sub>, AA<sub>aer.</sub>, CHO<sub>aer.</sub>), the contribution of the identified components to the OC was  
763 calculated. Furthermore, the OC contribution of recently identified components from previous  
764 campaigns within the Cape Verde region, in detail: aliphatic amines, methane-sulfonic acid  
765 (MSA), oxalic acid and carbonyls (van Pinxteren et al., 2015) was included. The OC contribution  
766 of the single compounds and compound groups are shown in Fig. 5 (values in Tab. S87).  
767 Altogether, about 48% of the average OC could be explained by the identified components.  
768 Regarding the maximum (0.31  $\mu\text{g m}^{-3}$ ) and minimum (0.13  $\mu\text{g m}^{-3}$ ) OC concentrations within  
769 the campaign, the OC contributions of the respective compounds are between 31% (lower  
770 limit) and 74% (upper limit). The major identified OC fraction (related to the average OC) were  
771 the Lipids<sub>aer</sub> with 43%. They were followed by the aliphatic amines (4%) that is in good  
772 agreement with a recent CVAO study, where they contributed on average with 5% to the  
773 (water-soluble) OC (van Pinxteren et al., 2019). MSA (0.9%) and oxalic acid (0.3%) were minor  
774 OC contributors. Similarly, the CHO<sub>aer</sub> and the AA<sub>aer</sub> made up a minor percentage with 0.3 and  
775 0.4% respectively. Regarding the lipids, it needs to be ~~taken into account~~considered that the  
776 ~~here performed~~ analysis performed here was not based on the detection of individual analytes  
777 but on an organic solvent extraction of the particle constituents and extract separation by  
778 solvents with different polarities applied in the TLC. The analytical method has been optimized  
779 for seawater analysis. Within atmospheric processing, additional organic compounds can  
780 form, which might contain a hydrophobic part and are potentially included in the lipid analysis  
781 performed here. However, the large similarity of the lipid groups within the seawater and the  
782 aerosol particles, as well as the agreeing concentrations of the single lipid groups (FFA, ALC)  
783 to measurements from other marine stations with molecular techniques (GC-MS) suggests  
784 that the same compound classes were present in the particles. Future analysis of the lipid  
785 fraction with mass spectrometric techniques will help to better resolve this issue.

786

787

Figure 5

788

789

### 790 3.4.2 Non-identified, recalcitrant OC in aerosol particles

791

792            About 50% of the aerosol OC remained uncharacterized on a molecular and semi-  
 793 molecular level. The non-identified OC part may contain larger macromolecules that might be  
 794 composed of particulate or non-soluble forms in water (carbohydrates and proteins) or  
 795 organic solvents (lipids) that were removed in the performed analysis during the sample  
 796 preparation step. In addition, the unknown part might include component groups that belong  
 797 to the soluble carbohydrates or amino acids but are either too stable or too labile for the  
 798 sample preparation procedure (e.g. within the hydrolysis step). Moreover, other complex  
 799 molecules that cannot be captured with the ~~here applied~~ methods applied here likely add to  
 800 the unknown fraction including optical active parts summarized as chromophore dissolved  
 801 organic matter (CDOM), humic-like substances (HULIS), brown carbon and water-soluble  
 802 pigments. As mentioned above, NMR analysis showed that SSA contains a large fraction of  
 803 lipopolysaccharides comprising complex, macromolecular groups of sugars, esters, carbonyls  
 804 as well as acids and lipids (Facchini et al., 2008). However, these components have, not yet  
 805 been analysed in aerosol particles using chromatographic techniques. The uncharacterized  
 806 part may also contain particulate OC compounds, such as larger aggregates of marine gels or  
 807 gel-like particles like transparent exopolymer particles (TEP). High TEP number concentrations  
 808 in aerosol particles were recently identified in the Cape Verde region (van Pinxteren et al.,

809 2022) and high mass-concentrations of TEP (e.g.  $1.2 \mu\text{g m}^{-3}$  for  $\text{PM}_{10}$ ) were identified in the  
810 western North Atlantic atmosphere (Aller et al., 2017).

811 Kieber et al., (2016) suggested that the major OC component in submicron sea-spray  
812 particles is recalcitrant and recently Beaupre et al., (2019) proposed that 19 to 40% of the OC  
813 associated with freshly produced marine aerosol particles was refractory dissolved OC. This  
814 percentage agrees with the non-identified OC part from the present study. However, we  
815 cannot identify or classify the remaining OC fraction nor attribute it with certainty to the  
816 recalcitrant OC. Further studies of the OC, in tropical as well as in other areas of the world, are  
817 needed to continue resolving OC and related transfer and formation processes. Nevertheless,  
818 the potentially recalcitrant OC fraction in the ~~here investigated~~-oligotrophic region does not  
819 seem to constitute the majority of OC as reported by Kieber et al., (2016).

820

### 821 3.5 Sea-to-air fluxes of the individual OC groups

822

823 The CVAO is localized in an oligotrophic region and should therefore be reasonably  
824 representative of most of the Earth's ocean surface. POA emission rates are strongly varying,  
825 however modelling studies have estimated global submicron marine POA emission rates of  
826  $10 \pm 5 \text{ Tg yr}^{-1}$  (Gantt and Meskhidze, 2013). Based on this emission flux and the contribution of  
827 the compounds to the OC fraction, we estimated the fluxes of the DAA, DL, and DCHO.  
828 Accordingly, the annual rates of emission from the ocean to the atmosphere are  $0.03 \pm 0.01 \text{ Tg}$   
829  $\text{yr}^{-1}$  for DCHO,  $0.04 \pm 0.02 \text{ Tg yr}^{-1}$  for DAA, and  $4.2 \pm 2.1 \text{ Tg yr}^{-1}$  for DL. The unknown OC that  
830 includes the potentially recalcitrant components, has a sea-to-air flux of  $4.8 \pm 2.4 \text{ Tg yr}^{-1}$ .  
831 However, this approach only includes the bubble-bursting-mediated transfer of the respective  
832 compounds, neglects any potential seasonal changes and neglects additional sources and  
833 formation processes. Ervens and Amato (2020) investigated the global impact of bacterial  
834 processes on carbon mass in cloud water and estimated formation rates of  $3.7 \text{ Tg C yr}^{-1}$  of  
835 secondary biological aerosol that are in the range of the POA emissions via sea spray (Gantt  
836 and Meskhidze, 2013). Hence, the ~~here presented~~ emission fluxes presented here can change  
837 once such processes are quantified for these compounds.

838

## 839 4 Summary and Conclusions

840

841 A comprehensive chemical investigation of the OC in the tropical Atlantic Ocean and  
842 the atmosphere with a focus on its contribution to the OC on the marine aerosol particles in  
843 this particular region was performed.

844 Regarding seawater, a similar distribution of the DL and DCHO was found with a small  
845 SML enrichment. However, the DAA, and likely the N-containing compounds in general,  
846 exhibit a high and varying enrichment in the SML (although being less surface active than  
847 lipids). Although conclusions on the detailed processes that lead to the varying DAA  
848 concentrations and the high SML enrichments cannot be resolved here and the sample  
849 number is limited, the results ~~clearly suggest show~~ that processes leading to changes in the  
850 organic matter composition within the upper 100  $\mu\text{m}$  oceanic layer are more pronounced for

851 the group of amino acids (and possibly for nitrogen groups in general) compared to other  
852 organic compounds groups such as lipids and carbohydrates. The SML is probably a very  
853 complex, heterogeneous, seasonality-dependent, and reactive matrix forming a lipid-rich  
854 nanolayer.

855 The same compounds studied in the seawater were found on the ambient submicron aerosol  
856 particles and strongly enriched ~~towards~~ with respect to sea salt ( $EF_{aer.} = 10^3$  for the  
857 carbohydrates and the amino acids). To this end, the lipids were even ~~stronger~~ more enriched  
858 in the submicron aerosol particles ( $EF_{aer.} = 10^5$ ) compared to the other groups. This indicates a  
859 preferred transfer of the lipids (towards the carbohydrates and the amino acids) from the  
860 ocean to the atmosphere ~~that is probably~~ likely driven by their physicochemical properties  
861 (high surface-activity and/or the lipophilic character). Detailed molecular analysis of the  
862 seawater and aerosol particles revealed changes in the relative composition of the single  
863 compounds. They were most pronounced for the amino acids and are likely related to an in  
864 situ atmospheric processing by biotic and/or abiotic reactions that require further  
865 investigations. A high saccharide fraction, as described in other studies, could not be found on  
866 the aerosol particles, at least when regarding the molecular-resolved carbohydrate analysis.  
867 However, saccharidic-like components (e.g. glycolipids) are also included in the lipid fraction  
868 analysed here in non-negligible concentrations. This shows that when comparing the  
869 concentrations of substance groups, the analytical methods used must be taken into account.  
870 Nevertheless, even small concentrations of carbohydrates and amino acids on marine aerosol  
871 particles can have a high impact in their microphysical properties, e.g. as ice nucleating  
872 particles, and are worth further studying.

873 Altogether, the marine aerosol particles analysis applied here shows that half of the  
874 OC can be attributed to specific components or component groups. However, the molecular-  
875 level analysed fraction explains only a small part of the OC, the  $CHO_{aer}$  and  $AA_{aer}$  made up less  
876 than 1%. This shows that the typical representatives of carbohydrates and amino acids within  
877 the marine OC measured here can explain only a very small fraction of the organic composition  
878 of the aerosol particles on a molecular level. Amines, MSA, oxalic acid carbonyls comprise a  
879 fraction of around 6%. Lipid analysis ~~unravel~~ ~~reveals~~ reveals 43% of the OC on the aerosol  
880 particles, however, the  $Lipid_{aer}$  composition on a molecular level cannot be obtained from the  
881 ~~here performed~~ measurements performed here. Altogether, about 50% of the OC remained  
882 uncharacterized on a molecular and semi-molecular level. Regarding further marine aerosol  
883 analysis, it will be important to resolve the large part of lipid compounds in more detail, as  
884 well as getting molecular-level information on the remaining, unidentified OC. This shows the  
885 need for further detailed analytical OC studies in the marine environment to resolve formation  
886 and transfer mechanisms.

887 Nevertheless, the results obtained here show that even in such an oligotrophic region,  
888 at least half of the OC on the aerosol particles consists of rather short-lived biogenic material,  
889 likely from the surface ocean, as (qualitatively) suggested by other studies (Choi et al.,  
890 2019;Schmitt-Kopplin et al., 2012). The non-resolved OC might in part be of recalcitrant  
891 nature, as indicated in other studies (Beaupre et al., 2019;Kieber et al., 2016;Lawler et al.,  
892 2020). However, the (potentially) recalcitrant OC does not constitute the majority of the OC

893 in the oligotrophic Atlantic Ocean. Future studies should complement the ~~here achieved~~ data  
894 presented here with investigations of the particulate OC fraction.

895 Finally, since large parts of the open oceans are oligotrophic, the findings of this study  
896 might be relevant to the majority of the world oceans.

897

898 Data availability. The amino acid and carbohydrate data are listed in the SI. The lipid data are  
899 available through the World Data Centre PANGAEA under the following link:  
900 <https://doi.org/10.1594/PANGAEA.921832> (Triesch et al., 2020). Further data can be made  
901 available by the authors upon request.

910 Foundation) – Projektnummer 268020496 – TRR 172, within the Transregional Collaborative  
911 Research Center “Arctic Amplification: Climate Relevant Atmospheric and Surface Processes,  
912 and Feedback Mechanisms (AC)<sup>3</sup>” in sub-project B04. We thank the CVAO site manager Luis  
913 Neves, René Rabe and Susanne Fuchs for technical and laboratory assistance. We further  
914 acknowledge the professional support provided by the Ocean Science Centre Mindelo (OSCM)  
915 and the Instituto do Mar (IMar). SF acknowledges the support of the Croatian Science  
916 Foundation under IP-2018-01-3105 BiREADI project. Finally, the authors thank Simeon Schum  
917 for the review of the English language and two anonymous referees for their helpful input.  
918 The study contributes to the international SOLAS program.

919

920 Author contributions

921 MvP led the MarParCloud campaign with support from KWF and HH. SZ performed the  
922 analytical measurements of the carbohydrates and supported the data analysis. SF was in  
923 charge of the lipid measurements. NT performed the measurements of the amino acids. MvP  
924 performed the data interpretation and wrote the manuscript with contributions from all  
925 authors.

926

927 Competing interest

928 The authors declare that they have no conflict of interest.

**Caption of Figures:**

Figure 1: Box and whisker plot of the concentrations in seawater ( $\mu\text{g L}^{-1}$ ), distinguished into SML and bulk water for the dissolved amino acids (DAA) in the SML ( $n = 6$ ) and in bulk water ( $n = 6$ ), the dissolved carbohydrates (DCHO) in the SML ( $n = 3$ ) and in bulk water ( $n = 3$ ) and for the dissolved lipids (DL) in the SML ( $n = 6$ ) and in bulk water ( $n = 13$ ). Each box encloses 50% of the data with the mean value represented as an open square and the median value represented as a line. The bottom of the box marks the 25% limit of the data, while the top marks the 75% limit. The lines extending from the top and bottom of each box are the 5% and 95% percentiles within the data set, while the asterisks indicate the data points lying outside of this range (“outliers”).

Figure 2: Bar graph showing the average of the relative compositions (mol%) of dissolved lipids (DL) and *Lipids<sub>aer.</sub>* (a), dissolved carbohydrates (DCHO) and *CHO<sub>aer.</sub>* (b) and dissolved amino acids (DAA) and *AA<sub>aer.</sub>* (c) in the bulk water (blue bars), the SML (orange bars), and the  $\text{PM}_{10}$  aerosol particles (grey bars). Mol% were calculated from the molar masses of the respective analytes. For the lipid groups, the molar masses of the surrogate standard (sec. 2.2.2 and Tab. S8) are applied. The relative mol fractions are relative to the total of each type (DAA, DCHO, and DL) analysed.

Figure 3: Box and whisker plot of the concentrations in the  $\text{PM}_{10}$  aerosol particles ( $\text{ng m}^{-3}$ );  $n = 8$  for *CHO<sub>aer.</sub>*,  $n = 7$  for *AA<sub>aer.</sub>*,  $n = 14$  for *Lipids<sub>aer.</sub>*. Each box encloses 50% of the data with the mean value represented as an open square and the median value represented as a line. The bottom of the box marks the 25% limit of the data, while the top marks the 75% limit. The lines extending from the top and bottom of each box are the 5% and 95% percentiles within the data set, while the asterisks indicate the data points lying outside of this range (“outliers”).

Figure 4: Scheme underlining the seawater (SML and bulk water) as well as the  $\text{PM}_{10}$  relative compositions of DL / *Lipids<sub>aer.</sub>*, DCHO / *CHO<sub>aer.</sub>* and DAA / *AA<sub>aer.</sub>*. Assignment: amino acids: neutral/polar: Phe, Gly, Ser, Tyr, neutral/non-polar: Thr, Ala, Pro, Val, Leu, Iso, acidic: Asp, Glu; carbohydrates: basic: GlcN, GalN, neutral: Fuc, Rha, Ara, Gal, Glc, Xyl, Man, acidic: MurAc, GasAc, GlAc; lipids: hydrocarbons (HC), sterols (ST), pigments (PIC), fatty acid methyl ester (MW), membrane component: WE, metabolic reserve: TC, degradation lipids: FFA, ALC, 1,3 DG, 1,2 DG, MG, glycolipids: MGDG, DGDG, SQDG, polar lipids: PE, PG, PC.

1344 Figure 5: Graph showing the identified and non-identified OC and the OC contribution of the  
 1345 respective organic compound groups in the PM<sub>1</sub> aerosol particles. The contribution of the  
 1346 measured organic compounds to the total OC fraction was calculated on a carbon basis.

 1358

1359 Table 1: Average concentrations of the organic groups and enrichment factor (EF) in the SML  
 1360 ( $EF_{SML}$ ) and in the aerosol particles ( $EF_{aer.}$ ) after equations 1 and 2. EF are calculated from the  
 1361 average concentrations of the respective groups (values in Tab. 1). For  $EF_{aer.}$  the average Na<sup>+</sup>  
 1362 concentration in seawater (1.0E+04 mg L<sup>-1</sup>) and the average Na<sup>+</sup> concentrations in the PM<sub>1</sub>  
 1363 particles from the MarParCloud campaign (100 ng m<sup>-3</sup>, values from Triesch et al., (2021b))  
 1364 were applied. To investigate the variability of the  $EF_{aer.}$ , the minimum ratio of  $c_{(analyte)aer.} / c_{(Na+)aer.}$  vs. the maximum ratio of  $c_{(analyte)seawater} / c_{(Na+)seawater}$  was applied (and vice versa) and  
 1365 the range of  $EF_{aer.}$  is given in brackets.  
 1366 For comparison, the last column lists the  $EF_{aer}$  for PM<sub>1</sub> from a chamber study (Rastelli et al.,  
 1367 2017).
