Figure S8. [NO$_2^-$]/[NO$_3^-$] in water-extract of aged particles.

Figure S9. RPA of total nitrate as a function of RPA of formate.

Figure S10. [Formate]/[K$^+$] as a function of [NO$_3^-$]/[K$^+$] in the water-extract of fresh and O3-Dark-aged incense burning particles.

Figure S11. The whisker-box plot of the [K$^+$] in the particle water-extract measured by IC normalized by the total counts of collected particles for IC measurement.

Figure S12. The difference of the average organic spectra of UV-aged particles and the NF ratio of UV-aged particles to fresh particles.

Figure S13. Relation between the particle collection efficiency of Polystyrene Latex particles and diameter in SPAMS.

Figure S14. Evolution of [NOx] under different OH exposure as a function of time.

Figure S15. The NF ratios of oxalate and malonate, and TOC ratios as a function of [O$_3$] in O$_3$+UV aging experiments.

Figure S16. The total organic content (TOC) ratios of aged to fresh particles extract.

Figure S17. Size distribution of O$_3$-UV-aged particles and their dicarboxylate-containing fractions.

Figure S18. The GF of KCl and KNO$_3$ particles as a function of RH.

Figure S19. The NF ratio of aged particles to fresh particles.
**Figure S20.** The NF of new organic peaks in aged particles.

**Table S1.** The classification of particles and RPA of total nitrate peaks of aged particles at different laser fluences.

**Table S2.** Potential peaks from the inorganics and elemental carbons.

**Text S1.** Estimation of the OH exposure.

SO₂ was used to calculate the OH exposure in the Go:PAM. The UVC lamps were turned on to warm up for ~30 min and turned off. Then, O₃ (300, 800, 1500 ppb) and SO₂ (~200 ppb) were introduced to the Go:PAM with the UVC lamps turned off until its initial concentration remained constant at steady-state conditions, which typically took around 5 min. The [SO₂] was recorded as [SO₂]_{Initial}. After that, the UVC lamps were turned on until the final [SO₂] stabilized and was recorded as [SO₂]_{Final}. The time scale for the stabilization of [SO₂] was around 4 min. The OH exposure at each condition is calculated using Eq. (A1):

\[
OH\ exposure = \frac{1}{k_{OH,SO_2}} \times -\ln \left( \frac{[SO_2]_{Final}}{[SO_2]_{Initial}} \right)
\]  

(A1)

where \(k_{OH,SO_2} = 9 \times 10^{-13} \text{ cm}^3 \text{ molec}^{-1}\) is the bimolecular rate constant between OH and SO₂ (Davis et al., 1979). The equation above is the result of integrating the differential rate equation for SO₂ and assuming pseudo-first order kinetics. The estimation of external OH reactivity (i.e., the OH reactivity with VOCs) requires VOC analysis and is not available in our study. Therefore, the OH exposure shown in this study may have been underestimated.

**Text S2.** Estimation of the mass hygroscopic growth factor (GF) by AIOMFAC model.

Based on the AIOMFAC model (Zuend et al., 2008), we obtained the weight fraction \(w\) of water and solutes (i.e., dry particles) in KNO₃ and KCl particles, respectively. Then, the GF is estimated as equation A2:

\[
GF = \frac{m_{wet}}{m_{dry}} = \frac{m_{dry} + m_{water}}{m_{dry}} = 1 + \frac{m_{water}}{m_{dry}} = 1 + \frac{w_{water}}{w_{dry}}
\]  

(A2)
where \( m_{\text{wet}} \), \( m_{\text{dry}} \), and \( m_{\text{water}} \) are the mass of wet particle, dry particle, and particulate water at different relative humidity (RH), respectively. The GF of KNO\(_3\) and KCl particles as a function of time is shown in Figure S18. We did not consider efflorescence in the figure since the efflorescence RH for the KNO\(_3\) and KCl are around 50\%, much lower than 80\% used in this study.

**Text S2.** The evolution of organic fragments.

We only showed NF ratios larger than 1 to focus on SOA formation. The positive spectra of both O\(_3\)-Dark-aged and O\(_3\)-UV-aged particles show NF increases for +30[NO] or [CH\(_2\)NH\(_2\)] (possibly due to nitrates, oxidized NOC, or amine), +44[CO\(_2\)] or [N\(_2\)O] (oxidized organics), +53[C\(_4\)H\(_5\)] and +69[C\(_3\)H\(_9\)] (aromatic hydrocarbons) (Wang et al., 2009; Silva et al., 2000; Dall'osto et al., 2013) (Figure S19). The negative spectra show increases for -137[C\(_8\)H\(_9\)O\(_2\)] (possibly methyl guaiacol) (Pagels et al., 2013; Gaie-Levrel et al., 2012) and -57[C\(_2\)HO\(_2\)] (a glyoxylate fragment) (Sullivan et al., 2007; Cheng et al., 2017), as well as -16[O]. O\(_3\)-UV-aged particles showed 200-folds and 10-folds NF increases for -137[C\(_8\)H\(_9\)O\(_2\)] and -57[C\(_2\)HO\(_2\)], respectively, significantly greater than that for UV-aged particles (~2-folds). Compared to OH chemistry, the UV photoactivity of compounds in particulates contributes minorly to organic chemistry (Figure S19).

Figure S20 show the NF of the new peaks in aged particles, which cannot (Dall’osto et al., 2009) be shown in the NF ratio plot due to their absence in fresh particles (zero denominator). O\(_3\)-Dark-aged particles show NF decreases of m/z +186 to +189 (probably PAHs) (Dall’osto et al., 2009) with increasing [O\(_3\)]. In contrast, O\(_3\)-UV-aged particles show NF increases of -31[CH\(_3\)O] or [HON], +123[C\(_7\)H\(_7\)O\(_2\)] and +124[C\(_7\)H\(_8\)O\(_2\)] (probably guaiacol) (Diab et al., 2015), and m/z +140 (probably HULIS) (Qin et al., 2006) with increasing OH exposure. These apparent changes in NF of organics fragments indicate the oxidative evolution of organics and likely formation of SOA, although the molecular characterization was hindered by severe fragmentation.
**Figure S1.** The schematic of the experimental set-up. The NOx analyzer and the VOC sensor were used only in the experiment for determining the gas removal efficiency and NOx decay under OH exposure.
Figure S2. The appearance of the incense sticks.

Figure S3. The emission spectrum of the UVC lamps.
Figure S4. RPA of summed nitrate peaks of aged incense burning particles in the presence and absence of charcoal absorber.

Figure S5. NF of oxalate and malonate of O$_3$-UV-aged incense burning particles (1500ppb O$_3$ + UV) in the presence and absence of a charcoal absorber.
Figure S6. Positive (K- and OC-) and negative spectra (-ON, -ONEC, -Cl, -N, and -ONN) of different categorizations of particles. The spectral characteristics of these categories are similar under different conditions.
Figure S7. APA of ON as a function of APA of total nitrate in fresh and O₃-Dark-aged particles.

Figure S8. [NO₂⁻]/[NO₃⁻] in water-extract of aged particles. Noted that the NO₂⁻ in 800ppb O₃+UV and 1500ppb O₃+UV experiments are undetectable.
Figure S9. RPA of total nitrate as a function of RPA of formate.

Figure S10. [Formate]/[K⁺] as a function of [NO₃⁻]/[K⁺] in the water-extract of fresh and O₃-Dark-aged incense burning particles.
Figure S11. The whisker-box plot of the [K⁺] in the particle water-extract measured by IC normalized by the total counts of collected particles for IC measurement. The error bar shows one standard deviation. We assume there was no new particle formation under ozone exposure since the WCPC showed comparable particle number concentration in the presence and absence of ozone.

Figure S12. (a) The difference (aged minus fresh) of the average organic spectra of UV-aged particles; (b) The NF ratio (aged to fresh) of UV-aged particles to fresh particles, as a function of m/z [-150, 150].
Figure S13. Relation between the particle collection efficiency of Polystyrene Latex particles and diameter in SPAMS.

Figure S14. Evolution of [NOx] under different OH exposure as a function of time. The shadings show one standard deviation. The [NOx] was equilibrated without O₃ and UV at 0 min.
Figure S15. The NF ratios (aged to fresh) of oxalate and malonate, and TOC ratios as a function of [O₃] in O₃+UV aging experiments.

Figure S16. The total organic content (TOC) ratios of aged to fresh particles extract.
Figure S17. Size distribution (0.2-2 μm) of O₃-UV-aged particles (at 1500 ppb O₃ and UV) and their dicarboxylate-containing fractions. The shadings show one standard deviation.

Figure S18. The GF of KCl and KNO₃ particles as a function of RH. The red line denotes 80% RH.
Figure S19. The NF ratio (aged to fresh) of (a) O$_3$-Dark-aged, (b) O$_3$-UV-aged particles to fresh particles, as a function of m/z [-150, 150].

Figure S20. The NF of new organic peaks in aged particles.
